Most of the time the historical categories of the book are entirely conventional—superficial generalities about "rising middle classes", or about scientific, industrial, political 'revolutions'. Its historical judgments are at times, indeed, out of date. Although footnote homage is duly paid to the late Sir Lewis Namier, the text (p. 366) still asserts that George III "was determined to impose an absolute rule on America as on England". When more original the authors are apt to be extravagant. The resistance to Charles I after 1630 is described as "the first major revolution in the world" (p. xvii). The assertion that "the experience of the French Revolution and of Napoleon, the philosophy of a Hegel, marks (*sic*) the transition from dynastic empires and tradition to nation states and charismatic authority" (p. xvi) leaves inexplicable the next hundred years of European history, which saw the creation of new dynastic empires in France and Germany and their cheerful survival in Austria-Hungary, Russia and Turkey.

Nor are the authors consistently true to their avowed method. How can they hope to explain the ideas of the late-seventeenth century, including their all-important scientific revolution, without giving much more systematic attention to events and conditions in the Netherlands, or a clearer picture of the English Civil War? They are shaky on economic history (even apart from allegations that historians neglect the steam-engine), and whether on enclosures in England or serfdom in Europe they commit vague and misleading assertions. They (or their indexer) confuses Robert Walpole with Horace: and to speak of Rousseau's "one-party view" is to misunderstand a vital part of his theory. On the Royal Society and the Lunar Society of Birmingham the authors have much to say that is interesting but scarcely original.

However, when all these substantial defects have been noted, the book has its uses and its value. It is, on the whole, a successful piece of intellectual regurgitation. It is written in a lively, easy style, confident if sometimes over-confident. It has excellent bibliographical notes and admirable brief summaries of the main historical controversies. It directs attention, at least, to the need to widen and deepen and experiment in the study of intellectual history. As a piece of popularization it is enterprising, efficient, and as good as most. It is not more than that.

D. THOMSON

A TEXT-BOOK OF SURFACE CHEMISTRY

Physical Chemistry of Surfaces

By Arthur W. Adamson. Pp. xiv+629. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1960.) 96*s*.

PROF. ADAMSON has written a very useful text-book of surface chemistry, well balanced, full, and as up to date as anyone is likely to achieve in these days of over-voluminous and often hasty publication. It covers most of the field, including chapters on capillarity, the thermodynamics of liquid-vapour interfaces, surface films on liquids, electrical aspects of surfaces, and long-range forces. Five chapters deal with solid surfaces, one being a brief introduction to chemisorption and catalysis; and in three more, various practical applications, including wetting and detergency, flotation of minerals, emulsions and foams, and friction and lubrication, are competently discussed.

Very sensibly, the author has made good use of several earlier books, and he has added, and usually succeeded in satisfactorily incorporating, a very large amount of later work. The book is written primarily for first-year graduate students in American universities, but it should also be valuable to senior undergraduates and to anyone desiring to learn the principles, and many of the details and applications, of the subject. Many, indeed, who have carried out considerable research on surfaces can learn much from this book, in those parts of surface chemistry in which they are not specialists.

The book is also remarkably clearly written, with numerous useful analogies: for example, the difficulty of defining the area of a surface is compared with the difficulty of deciding what should be taken as the coast-line of Maine. There are a number of problems for the reader to work out at the end of many of the chapters: some of these are ingenious, and admirably suited to test the student's understanding.

I have few criticisms: perhaps there are more mistakes in historical matters, assignment of priority in discovery, dates, and spelling of names, than might have been expected: but once detected, these can easily be rectified in future printings. In places, particularly in discussing heterogeneous catalysis, he follows the modern fashion of attaching names to theories and mechanisms, and these are not always those of the originators. Few people realize that it was Langmuir who, in 1922, published quite detailed and well-worked-out kinetics of catalytic oxidation, assuming reaction between adsorbed atoms of oxygen and molecules colliding from the gas phase: yet in this book, as unfortunately in much current literature, another name is given to this mechanism while Langmuir's name is attached to a mechanism which, so far as I am aware, he did not advocate. Too frequent attachment of names, according to current and sometimes local fashion rather than historical fact, renders a large majority of papers unreadable to anyone outside the immediate circle of specialists to which the author happens to belong, and should be avoided if possible in text-books.

Apart from these quite minor blemishes, Prof. Adamson has made a most valuable contribution to the literature of, and education in, surface chemistry, and deserves hearty congratulation. The same cannot be said of the publishers, who have fixed a price that may well put the book out of reach of large numbers who would profit by owning it.

N. K. ADAM

ADVANCES IN INORGANIC CHEMISTRY

Advances in Inorganic Chemistry and Radiochemistry

Vol. 2. Edited by H. J. Emeléus and A. G. Sharpe. Pp. viii+392. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1960.) 12 dollars.

THE titles of the reviews in this volume are as follows: "Stereochemistry of Ionic Solids", by J. D. Dunitz and L. E. Orgel: "Organometallic Compounds" by J. Eisch and H. Gilman; "Fluorine-containing Compounds of Sulphur" by G. H. Cady; "Amides and Imides of the Oxyacids of Sulphur" by M. Becke-Goehring; "Halides of the Actinide Elements" by J. J. Katz and I. Sheft; "Structures of Compounds Containing Chains of Sulphur Atoms" by O. Foss; "Chemical Reactivity of the Boron Hydrides and Related Compounds" by F. G. A. Stone; and "Mass Spectrometry in Nuclear Chemistry" by H. G. Thode, C. C. McMullen and K. Fritze.

From the long-term point of view, the most important articles are probably the first two, which attempt explanation as well as summary. The chapter by Dunitz and Orgel should be read by anyone professing a knowledge of structural inorganic chemistry. Three of the other chapters are devoted to various aspects of the chemistry of sulphur and reflect the current great interest in the chemistry of the elements of the second short row of the Periodic Table—although it is rather unfortunate that there is some overlap between the article on sulphur acid amides and a recent review on sulphur–nitrogen chemistry in *Progress in Inorganic Chemistry*. The chapter on mass spectrometry is devoted largely to the study and theory of fission yields. From the point of view of physical techniques this volume has two chapters devoted to results derived by X-ray crystallography. This should emphasize that the only absolute method of structural determination is by crystallography, and it is to be hoped that these reviews will stimulate further the interest of crystallographers in the structures of inorganic compounds.

Both in the standard of articles and of production, this volume is fully up to the high standard of the first of the series. The general state of health of inorganic chemistry is shown by its apparent ability to support both this series and the parallel series of *Progress in Inorganic Chemistry*. There is a risk that there will soon be almost as many chemists writing reviews as are carrying out original work, but at the moment *Advances in Inorganic Chemistry and Radiochemistry* is proving an extremely useful and informative series.

D. W. A. SHARP

GRAPHITE: AN IDEALLY IMPERFECT MATERIAL

Graphite and its Crystal Compounds

By Prof. A. R. Ubbelohde and F. A. Lewis. Pp. xii+217. (Oxford: Clarendon Press; London: Oxford University Press, 1960.) 35*s*. net.

GRAPHITE is perhaps the best example of the fact that the regular three-dimensional structure of solids, so clearly revealed by the early work of von Laue and the Braggs, is only a first approximation to the truth. A study of its physical and chemical properties, many of which have become of great technical importance, reveals the significance of imperfections in the solid and demonstrates how far we are from possessing any refined means of measuring crystal defects.

It is against this kind of background that Ubbelohde and Lewis have written their monograph *Graphite and Its Crystal Compounds*, which brings together the vast literature on this subject for the first time. The authors do full justice to the fact that it is a wide range of materials which they are describing and not a single well-defined substance. During the past twenty years the number of technical uses and demands for graphite have greatly multiplied: for example, nuclear reactors have called for graphites with closely specified properties, such as purity, high-density and non-permeability. These needs have stimulated research by every kind of modern technique, but, as the authors say, our knowledge is still very uneven and imperfect. Their book provides a basic text as a starting point for the many physicists, chemists, engineers and others who seek to understand some aspect of graphite in relation to the wider, still imperfect, picture.

Rather more than half the book deals with graphite itself, in four chapters. The first of these is written from a crystallographic point of view, and sets out our present knowledge of 'ideal' graphite and the physical and chemical departures from this perfect model which make up the wide range of materials which are known and used. Emphasis is placed on the conception of graphite as the extreme case of the large aromatic molecule. Succeeding chapters deal with the more mechanical physical properties such as compressibility, elastic moduli and frictional behaviour and with the thermal properties and the thermodynamics of the graphite-diamond transformation. The latter discussion is followed by an account of related substances such as silicon, silicon carbide, boron nitride and borazon. Chapter 4, the longest in the book, collects together the large amount of data on electronic properties, derived from measurements of magnetic susceptibility, electrical conduction, thermoelectric power, Hall effect and optical properties.

The second half of the book deals with the chemical behaviour of graphite, as represented by the production at ordinary temperatures of the characteristic lamellar compounds (in which the carbon layers retain their identity largely unchanged) and by the conversion to volatile products at higher temperatures, sufficient to break up the bond structure, by oxidation or reaction with carbon dioxide, hydrogen or water. The lamellar compounds are classified broadly in terms of their bond structure and the electronic character of the predominating carbon macro-molecules. An account of their magnetic and electrical properties concentrates on showing how the general changes on compound formation, such as reduction of electrical resistance and of diamagnetic susceptibility, contribute to the general understanding of electron bands in graphite itself. A separate chapter is devoted to the still controversial structure of graphite oxide in which the carbon networks have probably become buckled. In the final chapter, on the complete chemical transformation of graphite, the emphasis is on the mechanism of the oxidation process, its dependence on surface and edge defects and crystalline perfection, with an eye, for example, on the development of oxidation-resistant graphites for refractories and nuclear reactors.

Throughout the book the discussion is extremely well furnished with literature references, and the list of these contains about a thousand entries, including many for 1959. The only obvious omission is the very recent work by electron microscopy which may have developed into a valuable contribution in time for a second edition, for this is assuredly not a subject where fact or interpretation will remain stationary for very long. G. E. BACON

ANIMAL BEHAVIOUR

Animal Behaviour

By Prof. J. L. Cloudsley-Thompson. Pp. xv+162+16 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1960.) 15*s*. net.

ALREADY it is traditional for books on animal behaviour to be illustrated by stylish photographs, and those accompanying Prof. Cloudsley-Thompson's text are exceptionally elegant. The text itself, unfortunately, is not of the same quality. The work is explicitly intended as a primer of animal behaviour for the non-specialist reader, and the diversity of the examples which are discussed makes for a certain freshness of approach; a discursive and imprecise presentation lessens their impact. Of nocturnal animals Prof. Thompson writes: "The carnivorous habit is less hazardous too at night, and competition is reduced when nocturnal carnivores such as beetles prey on sleeping diurnal forms such as butterflies". It is not only the layman who may be expected to find this type of generalization difficult to follow in the absence of any further exposition.

Many of the drawings appear to be merely decorative. For example, an account of phototonus in *Proctacanthus* on p. 9 is accompanied by a picture of two flies in bizarre attitudes, but the legend does not explain what has been done to them. Similarly, pp. 21–22 discuss neuro-muscular facilitation in the sea anemone, but the idealized kymograph tracings of the illustration bear no account of the method by which they were obtained. The number of different examples used to reveal the mechanisms of invertebrate behaviour precludes the adequate discussion of any one of them, and we are told little about the means by which zoologists have chosen to investigate them. This is a pity, for while controversy among behaviour workers may be highly technical, their experimental methods are often extremely simple, and of just the kind to appeal to the interested layman. The last chapter is headed "Displacement Activity and Human Behaviour", and is as superficial as its title would suggest. A. D. BLEST

Mambu

A Melanesian Millennium. By Dr. Kenelm Burridge. Pp. xxiii+296+17 plates (London: Methuen and Co., Ltd., 1960.) 42*s.* net.

MAMBU, pidgin English for bamboo, is in this work a name of a prophet of a millenium in which the spirits of the dead will bring the tools and consumers' goods of a developed culture for free distribution among their descendants of the Territory of Papua and New Guinea, who were recently of modern neolithic culture. The millenarian cargo-cult described began in the Territory more than sixty years ago, and has been previously discussed by several authors, including Haddon and Chinnery, Lawrence, Mead, Williams, Hanneman and Worsley. The cult has been viewed with some distaste by missionaries such as Hanneman, who notes that it is materialistic, and its prophets have, on occasion, been arrested by the administration, as they sometimes encouraged people to take no care for their self-subsistence, to slaughter their pigs and to build large and very quickly disused houses intended for the reception of the revenants with the tools and goods. Moreover, the prophets have sometimes preached that the secret of wealth was magical and was withheld from Papuans by missionaries, administrators, traders and settlers. There has not been a grave threat in the cult. Indeed, Hanneman noted with some disapproval of it that peoples of other countries organized revolutions, elections, changes of government, strikes and the writing of books on capitalism, democracy and utopia with aims of improving living conditions. The general idea in the discouragement of cargo-cult prophets has probably been to gain time until greater facilities for technical education are made available in the Territory, and until there are more Papuan students with an Australian education returned to it.

Dr. Kenelm Burridge describes incidents of the cargo cult in the Madang district and on the Island of Manam in good literary style and with a sense of the humour of situations. In particular, he discusses myths and dreams with appreciation of them, and what he terms the triangle of administrators, missionaries and Papuans with a detailed account of their angles.

R. F. FORTUNE

Fiori delle Ande

Da Alfonso Vinci. Pp. 68 (70 illustrations). (Bari: Leonardo da Vinci Editrice, 1960.) 1,500 lire.

THIS is the first pocket flower-book, of the kind so well known to us in Europe, for the Andes and perhaps for the whole of South America. The area covered is the complex series of sierras and páramos above Mérida, in Venezuela, but many of the plants illustrated have wide distributions in the Andes. The excellent short introduction, in Italian, describing the physical features, climate, geology and vegetation zones of the region, is far above the head of the average tourist and is more suited to the highly educated traveller or trained naturalist. Following this are three coloured illustrations of the three zones, tierra caliente, templada and fría. Then come the small pictures, 66 in number and also in colour, of individual flowers. The presentation of these is not worthy of the introduction, and has obviously been put together with undue haste. Many of the plants are described as "specie non determinata" or are assigned to wildly wrong families, when the identification is obvious to any botanist familiar with this flora. Yet the author thanks two distinguished local botanists for their help. It is a pity that this attractive little forerunner has been spoiled by such haste or lack of care. Even in the introduction there is the statement that *Draba* and *Pringlea*, in Cruciferae, are represented on the Andes, in the Alps and on the remote island of Kerguelen! At the top of p. 11 the second and third lines have been transposed.

N. Y. SANDWITH

Fundamentals of Nutrition

By E. W. Crampton and L. E. Lloyd. (Series of Books in Agricultural Science.) Pp. xi+494. (San Francisco and London: W. H. Freeman and Company, 1959.) 50*s.*

IN this text-book, which is planned as an introductory course in human and animal nutrition, related disciplines are briefly discussed in an opening chapter. The first section is concerned with nutrients and composition of the animal and of foods. In five further sections the subject is developed with regard to metabolism of protein, fat and carbohydrate, the nature of vitamins and of mineral elements, experimental studies on nutrition and nutrient requirements for man and animals. The text is illustrated with simplified diagrammatic representations of metabolic pathways and other physiological processes. Reading lists are appended to every chapter to encourage the student to become aware of the expanding literature on the subject of nutrition. The book would be a useful adjunct to a course in physiology where general principles of nutrition must be taught. While it does not set out to be a complete treatise on nutrition it does provide a good background to a wider study of the subject and can be recommended as a useful introduction to a rapidly growing science.

A. M. COPPING

Socrates and the Animals

By Dr. Elena Quarelli. Translated from the Italian by Kathleen Speight. Pp. 160. (London: Hodder and Stoughton, Ltd., 1960.) 12*s.* 6*d.* net.

MANY people are sentimental where animals are concerned, and attribute to them qualities that they do not possess—even anthropomorphic. Others go to the opposite extreme and dismiss them as objects incapable of life or feeling. In this book Dr. Elena Quarelli investigates the problem whether animals possess immortal souls. She does this both philosophically and logically.

She seeks information from Ancient Greek thinkers such as Aristotle and Plato, from the Bible and official representatives of Christian teaching, and from contemporary zoologists and animal psychologists. Her own theories are backed by personal experience of animals, and her anecdotes make interesting and amusing reading.

It was impossible to limit her inquiry solely to the animal world; the problem had to be seen within the context of the universe as a whole. She studies animals in relation to the whole purpose and meaning of life, including human beings. The book therefore has a sincerely religious and deep-thinking basis.

The writer combines a sympathetic but unprejudiced approach to the problem. Her findings will delight many, and can offend none.

B. J. G. MAITLAND

THE POSSIBILITY OF THERAPEUTIC APPLICATIONS OF BEAMS OF NEGATIVE π-MESONS

By DR. P. H. FOWLER and DR. D. H. PERKINS
H. H. Wills Physics Laboratory, University of Bristol

FOLLOWING a recent lecture by Prof. J. Rotblat given in the H. H. Wills Physics Laboratory at Bristol, on the applications of radiations in medicine, we have been led to consider the possibility of using beams of negative π-mesons for the treatment of tumours. It is well known that a serious limitation to such treatment, when γ-rays are employed, is the heavy dosage delivered to the healthy tissue in the path of the γ-rays. A typical distribution of the variation of dosage with depth, using γ-rays from cobalt-60, is shown in Fig. 2. Even when the dosage to the healthy tissues is distributed by employing several fields, the resulting toxæmia is commonly the factor limiting the amount of radiation which can be delivered to the tumour. In this situation, it occurred to us that beams of π^--mesons would have, at least in principle, a number of decisive advantages.

From the point of view of its nuclear composition, biological tissue can be regarded as made up of hydrogen, carbon, nitrogen and oxygen. When a π^--meson is brought to rest in such a medium it may be captured by any one of these atoms. When captured by hydrogen, however, the resulting π^--mesic atom migrates a short distance in the tissue until it encounters a heavier nucleus to which the π^--meson is handed over. As a result, all the π^--mesons interact, before decaying, with one or another of the nuclei carbon-12, nitrogen-14 or oxygen-16. In such interactions, about 20 per cent of the total rest-energy of the π^--meson, that is $\sim$ 30 MeV., appears in the form of α-particles and protons, very nearly all of which have ranges less than 1 mm. in biological tissue. A further 40 MeV. is expended in breaking up the nucleus, and the remaining 70 MeV. is carried off as fast particles, mostly neutrons, many of which (60–70 per cent) will escape from the tissue without interacting. For our present purposes, it is a favourable feature that capture of π^--mesons by light elements, especially carbon-12 and oxygen-16, leads to an exceptionally large release of energy in the form of short-range α-particles as compared with nuclear capture by other elements.

The range of a π^--meson of 52 MeV. is about 10 cm. in biological tissue, the maximum depth at which it is commonly necessary to irradiate tumours in the human body. If such a beam of particles is homogeneous in energy, there will be a straggling in range of about 2·5 mm. (see Appendix). Further, the scattering in the direction of motion of the particles as they pass through tissue, due to Coulomb interactions in distant collisions with nuclei, results in a lateral dispersion of their points of arrest relative to their original directions of motion.

The root-mean-square value of this lateral deviation is about 3 per cent of the mean range (see Appendix). For a range of 10 cm. therefore, most of

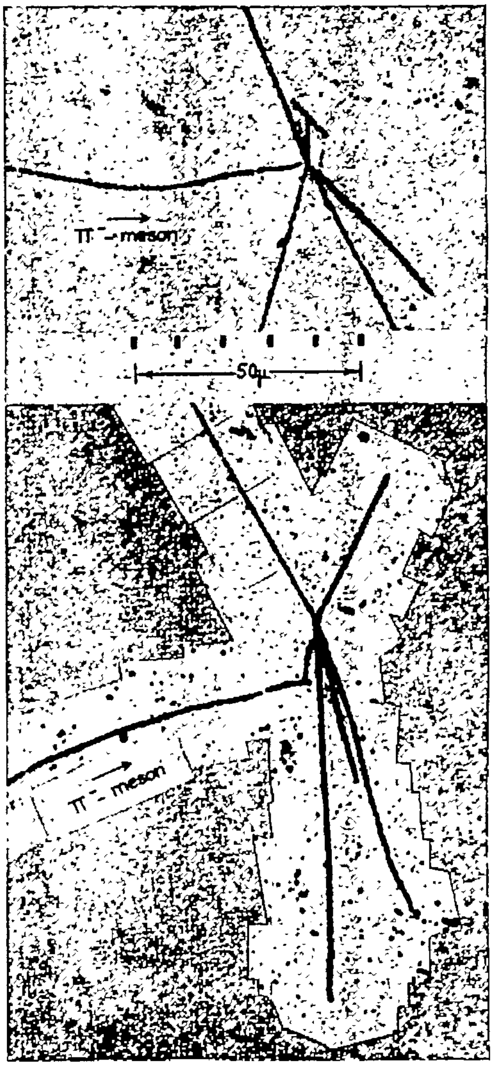

Fig. 1. Capture of negative π^--mesons: two photomicrographs of the nuclear capture of π^--mesons at rest in a nuclear emulsion. It is probable that each meson was captured by an oxygen nucleus of the gelatine. In the top example, one of the five charged secondaries is a nucleus of ^{8}Li. This nucleus undergoes β^--decay after being brought to rest, and produces two α-particles each of ≈ 2 MeV. that are emitted in opposite directions. The track of the β^--particle is not shown, as it dipped steeply with respect to the plane of the emulsion

In the lower example, it is probable that the charged secondaries were 2 α-particles and 3 singly-charged particles

In sensitive emulsions such as these, discrimination between tracks due to singly- and multiply-charged secondaries of short range is poor. In emulsions of lower sensitivity, the tracks of the singly-charged secondaries with range greater than ≈ 20μ can be picked out with confidence. The scale in microns gives the range of the secondaries in nuclear emulsion. Ranges in tissue would be about three times greater

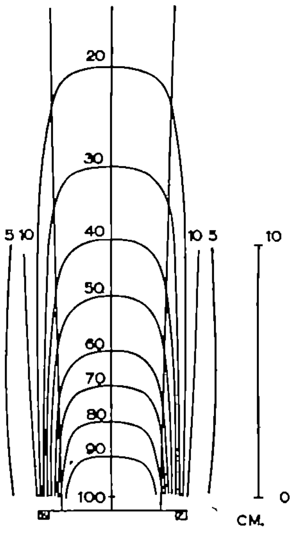

Fig. 2. Radiation field in biological tissue due to a collimated γ-ray beam from a cobalt-60 source

the points of arrest are distributed in a target area about 2 $cm.^3$ normal to the axis of the beam. The essential point emerges that the effective volume irradiated can be made less than the minimum volume of a tumour that it is usually considered desirable to treat.

In order to display the advantages of such a beam of π^--mesons, we show in Fig. 3 a calculated radiation field due to an initially parallel beam of these particles of energy 52 MeV. (range 10 cm. in tissue); the results may be compared with the computed field due to γ-rays in Fig. 2. The field produced by a proton beam of the same range is included. In each case, the beam at entry has a circular cross-section of area 2·2 $cm.^2$. In making the calculations, we have taken into account: (i) the change in loss of ionization of the beam as a function of depth; (ii) the effect of charged and neutral particles produced in the nuclear interactions of π^--mesons at the end of their range; (iii) the effect of the nuclear interactions in flight of the beam particles; and (iv) the effects of scattering and straggling on the dispersion of the beams.

In each case, no account was taken of the presence of other particles in the beam. In practice, a π-meson beam will contain an appreciable contamination of μ-mesons, electrons and neutrons, but we consider their effects could be made small.

In Fig. 3, the contours refer to the losses of ionization energy in rads (1 rad corresponds to an energy loss of 100 ergs/gm. in production of ion pairs). In order to obtain a numerical estimate of the distribution of the actual biological damage associated with this ionization, it is necessary to assume values for the relative biological damage per unit loss of energy, for the various radiations. This factor of relative biological efficiency is taken as unity for 220-keV. X-rays. It depends on the rate of loss of energy of the ionizing radiations, which are different in different regions of the radiation field. Along the path of the beams, the ionization is produced mainly by lightly ionizing particles, for which the relative biological efficiency will certainly be close to unity. In the region where the π-mesons are brought to rest, the ionization is mostly produced by heavily ionizing particles (mainly α-particles), for which the average value of the relative biological efficiency may be much higher, possibly about 6. At appreciable distances from the axis of the beam, the ionization is due to collisions of neutrons, for which the value of the relative biological efficiency is likely to be between 1 and 3. The details of the distribution of radiation damage will therefore depend on the sensitivity of the relative biological efficiency to the density of ionization of individual particles.

Unfortunately, there is at present no precise information on the values for relative biological efficiency of the different particles for the particular irradiation problem presented by the therapeutic treatment of tumours: a treatment which requires the destruction of practically all cells within a certain volume. For example, the U.S. National Bureau of Standards, in connexion with radiation protection[1], has recommended, for α-particles of energy a few MeV., a value of about 15. Snyder and Neufeld[2] have computed curves based on these recommendations for the radiation damage for various types of particles. On the other hand, direct measurements have been made by Storer *et al.*[3] for different

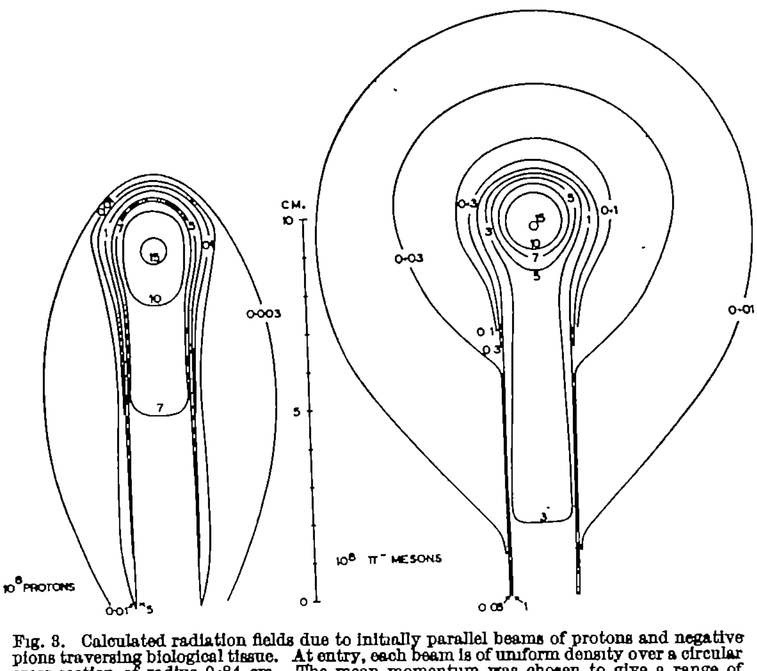

Fig. 3. Calculated radiation fields due to initially parallel beams of protons and negative pions traversing biological tissue. At entry, each beam is of uniform density over a circular cross-section of radius 0·84 cm. The mean momentum was chosen to give a range of 10 cm. in body tissue. The spread of momentum of each beam was taken to be rectangular in form and of total width given by $\Delta p/p = 4·5$ per cent; so that the most concentrated radiation damage occurs in a volume of roughly cylindrical form, of length equal to its diameter, centred at the end of the range (10 cm.)

In calculating the radiation intensity, allowance has been made for lateral Coulomb scattering of the beams and straggling in range. The total dose is made up of the effects of ionization loss due to (i) the incident beam and (ii) charged and neutral secondary particles from nuclear interactions of the protons in flight, and of the pions in flight and at rest. The numbers alongside the contours refer to the dose in rads for 10^8 incident pions, or protons

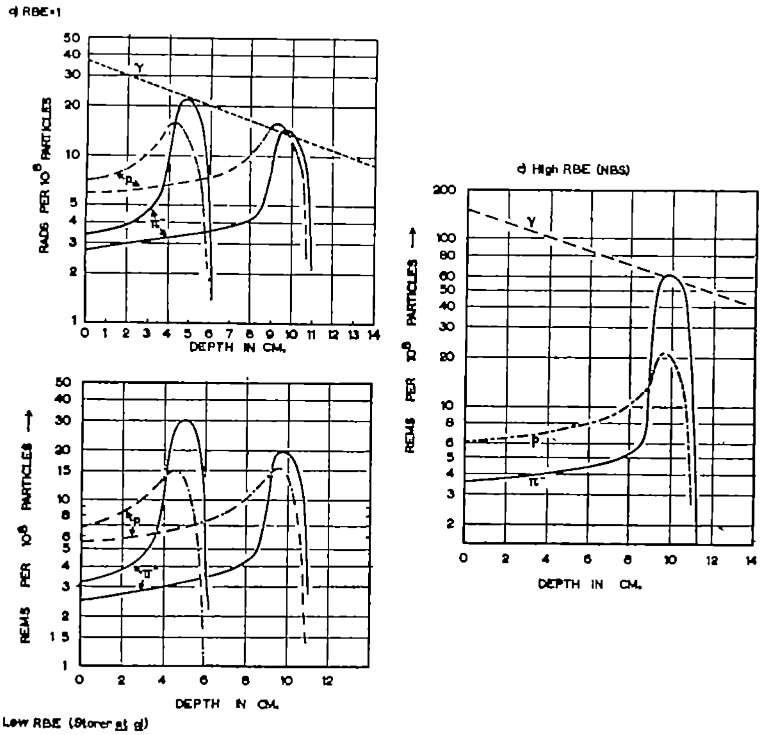

Fig. 4. (a) Axial radiation fields corresponding to the contours of Fig. 2. The (unnormalized) field due to a cobalt-60 γ-ray beam is also indicated
(b) and (c) Axial radiation fields of proton and pion beams of ranges 5 cm. and 10 cm. respectively, where the values for the relative biological effect of Storer *et al.* and the National Bureau of Standards recommendations are employed

particles producing lethal and other effects in rats and mice. For a variety of heavily ionizing particles, they obtain values of relative biological efficiency in the region 1·5–3·0. In view of these uncertainties, we have computed the distribution of radiation damage in rems (1 rem = 1 rad × relative biological efficiency) due to beams of negative pions, using in turn values of relative biological efficiency of unity for all particles, those of Storer *et al.*, and those recommended by the National Bureau of Standards. It seems probable that values appropriate to the present problem will lie between these extremes.

Fig. 4*a* represents the axial radiation dosage taken from the contours of Figs. 2 and 3. These fields correspond therefore to the use of a value of unity for relative biological efficiency. Fig. 4*b* shows the axial dose for π-mesons and protons assuming the values of Storer *et al.*[3], and Fig. 4*c*, that for the high values recommended by the National Bureau of Standards[1]. Calculations were made for ranges of both 5 cm. and 10 cm. The effect on the peak intensity of the lateral dispersion of the beam due to Coulomb scattering is very small for pions of 5-cm. range, and for protons of either range; but it reduces the peak intensity for pions of 10-cm. range by a factor of ~ 1·5.

The important feature illustrated by these results is that, whichever set of values for relative biological efficiency is taken, the dose received in a spherical volume centred near the end-point of the pion beams, and called here the 'tumour region', is much greater than that delivered in any of the surrounding tissue. The greatest dose outside the tumour region is of course in the path of the incoming beam, but the dose gradient even in this direction is very large.

The degree of concentration of the radiation damage in the region of the end-point is also illustrated in Table 1. These figures show the superiority of the pion irradiations over those by protons or γ-rays. The 'figures of merit' for the various beams have been specified in two ways: either by the ratio of the total dose delivered to the tumour to that in the whole of the surrounding tissue; or by the ratio of the dose per unit volume at the centre of the tumour to the maximum dose per c.c. delivered in a nearby region. For this purpose, we show the dose at the centre of irradiation divided by the maximum dose 1·5 cm. away from it.

The results show that, for single parallel beams of γ-rays and fast protons (and indeed neutrons), the radiation damage per unit volume in the tumour is no greater than that in the surrounding tissue, and that only a small fraction (less than 10 per cent) of the total body damage is confined to the tumour. Both these features are highly undesirable. In contrast, for a beam of π^--mesons, the damage per unit volume is many times greater in the tumour than in adjoining regions, and the total damage in the tumour region appreciably exceeds that in the whole of the surrounding body tissue. In principle, therefore, the advantages of a beam of π^--mesons appear to be very great.

The preceding results refer to irradiations over a tumour volume with linear dimensions of about 2 cm.; the lateral extent of the incoming beam, and the spread of momentum in the beams were so chosen as to irradiate such a volume nearly uniformly. If it were desired to treat a smaller volume, the characteristics of the beam could be altered accordingly.

In Fig. 5 we show the axial radiation field for pion and proton irradiations, with the fractional momentum spread of the beam, and its lateral extent, each reduced by a factor 2. This would correspond to irradiation of a tumour of one-eighth of the previous volume. The superiority of the π^--meson irradiation over the proton or γ-ray irradiation is apparent, and is somewhat more marked than when larger volumes are irradiated. The minimum volume within which one can restrict an appreciable fraction of the radiation damage is determined, for stopping particles, by the lateral spread produced by Coulomb scattering. As shown in the Appendix, this spread is nearly proportional to the depth of penetration (that is, the beam range).

Table 1

Radiation	(Tumour damage)/(External damage)		(Dose at tumour centre)/(Max. dose 1·5 cm. away)	
Tumour depth	5 cm.	10 cm.	5 cm.	10 cm.
Cobalt-60 γ-rays	0·11	0·07	0·9	0·9
Fast protons	0·08	0·08	1·0	1·0
Ending protons	0·9–1·3	0·4–0·6	1·4–1·9	1·4–1·9
π^--mesons	1·7–3·8	0·9–1·9	4·4–13	3·4–10

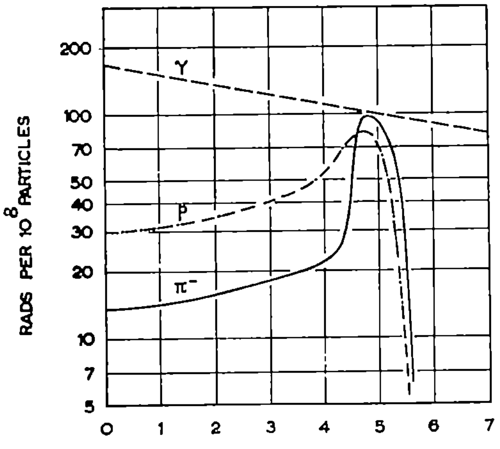

Fig. 5. Axial radiation field for the case of beams of radius 4 mm. and spread of momentum such that the particles end over a band of range 8 mm. in extent at a mean depth of 5 cm. Relative biological efficiency taken as unity for all particles

When employing γ-rays it is normal practice, in order to reduce the dose to healthy tissue adjacent to the tumour, to irradiate from several directions. The same advantage can be gained in the case of beams of low-energy protons or π^--mesons; for the latter, it may also prove practicable to produce a converging beam in a single exposure, because the momentum of the pions of the required range is quite low ($\approx$ 100 MeV./c.).

In view of these apparently great advantages, it appeared worth while to examine whether, with accelerators and their associated equipment at present available, which have been designed for the quite different purpose of making refined experiments with beams of fast elementary particles, it would be possible to secure irradiations of sufficient intensity in a reasonable time. For this purpose, on the basis of the results summarized in the figures, we estimate that a treatment of a tumour with an irradiation of 400 rems would require the arrest of up to 10^9 π^--mesons per c.c., or an incident beam of up to 5×10^8 pions/cm.^{2}, with a total spread of momentum of 4·5 per cent.

The Liverpool cyclotron, working with protons of energy 400 MeV. bombarding a thin beryllium target, can produce an analysed beam of π^--mesons of energy 90 MeV., and with a total spread of momentum of 4 per cent. The number of π^--mesons in the beam is $\sim 10^3$/cm.^{2}/sec. This beam is produced with a single quadrupole (focusing) magnet followed by a deflecting magnet for analysis of momentum. It is believed that a second stage of focusing would allow a large fraction of the original beam to be focused into a spot a few square centimetres in area. With the existing beam, the time of exposure required would therefore be up to 10^6 sec.

Doubtless improvements of intensity in a specially equipped machine could be secured by a suitable choice of the target element, by increasing the mean proton current and by employing focusing magnets of higher aperture, which would appear feasible for the low-momentum beams required. It seems likely also that the pion yield in the region of 50 MeV. could be made considerably bigger by a moderate increase in proton energy. In view of these factors, it appears not unreasonable to suggest that beams of π^--mesons 1,000 times more intense than those at present available in Liverpool would be technically feasible without any radical changes in present equipment, and that the shielding problem could be overcome. The corresponding exposure times for 10^9 particles would then be 1,000 sec.

These considerations make it desirable to determine in more detail the physical processes involved; and to make measurements of the actual distributions of the points of arrest of π^--mesons injected into biological tissue; on the distribution of the ionization due to both charged and neutral particles from the arrested π^--mesons; and of a number of other quantities. Such experiments are at present being designed and will be carried out in the near future. It will also be necessary to consider the question of the most advantageous forms of shielding from the high neutron fluxes generated at the target.

We may remark that our calculations indicate the marked superiority of beams of protons over γ-rays for therapeutic purposes. Although beams of protons are markedly inferior to pions, their production in sufficient intensity would be possible with technical methods already established, and they would have great advantages over γ-rays from cobalt-60.

Table 1 shows the ratio of the radiation dose delivered to a tumour compared with that in adjacent regions. The tumour is taken to be of radius 1·5 cm., and to be situated at a depth of 5 cm. or 10 cm. from the skin. In columns 2 and 3 the total external dose refers to that in a sphere of radius 10 cm. Calculations have been made for initially parallel beams of optimum width; and, for the low-energy protons and pions, with the optimum band of momentum. For columns 3 and 4 the figures apply to a single irradiation only. If irradiation is made from different directions, the values will increase by a factor which is practically the same for all four types of radiation.

The pair of figures given for the beams of slow protons and π^--mesons refer to a value of unity for the relative biological effect, and the high value recommended by the National Bureau of Standards, respectively. The fast-proton beam is assumed to be of sufficient energy to pass through the entire volume with only a small change in velocity.

Appendix

(*a*) *Lateral spread of a beam due to Coulomb scattering*. Consider a parallel pencil beam of initial energy E_0 and initial range R_0. Let $\overline{\alpha^2}$ be the mean square angle of multiple scattering of the particles in the beam per unit path-length when they possess residual range R. The total mean square lateral deviation of the points of arrest, $D_\perp{}^2$, is then given by:

$$D_\perp{}^2 = \int_0^{R_0} \overline{\alpha^2} R^2 \mathrm{d}R$$

$\overline{\alpha^2}$ for tissue is given by:

$$\overline{\alpha^2} = 10\cdot6/(p\beta)^2 \text{ (radians)}^2/\text{cm.}$$

where p is the momentum measured in MeV./c. and βc is the velocity of the particles at any point along their trajectory.

For the ranges R under consideration, $p\beta$ is given to sufficient accuracy for π-mesons by the relation:

$$p\beta = 24R^{0\cdot58} \text{ MeV./c.,}$$

where R is measured in cm.

Hence

$$\overline{D_{\perp}^{2}} = 1{\cdot}84 \times 10^{-6} \int_{0}^{R_0} R^{0{\cdot}84}\mathrm{d}R = 1{\cdot}0 \times 10^{-2} R_0^{1{\cdot}84}\ \text{cm.}^2$$

The root-mean-square projected value of $D_{\perp}$ along any direction perpendicular to the initial beam is $D_{\perp}/\sqrt{2}$ and is thus

$$D_{\perp\ \text{proj.}} = 7 \times 10^{-2} R_0^{0{\cdot}92}\ \text{cm.}$$

Thus for 52-MeV. π-mesons, for which $R_0 = 10$ cm., $D_{\perp\ \text{proj.}} = 0{\cdot}6$ cm. For other values of R_0, the ratio $(D_{\perp\ \text{proj}})/R_0$ remains almost constant. The lateral distribution of density of the points of arrest of the π-mesons at a distance D perpendicular to the beam is given by a Gaussian distribution:

$$\begin{aligned} I &= I_0 \exp - \frac{D^2}{2(D_{\perp\ \text{proj.}})^2} \\ &= I_0 \exp[-1{\cdot}4D^2],\ \text{for } R_0 = 10\ \text{cm.} \\ &= I_0 \exp[-5D^2],\ \text{for } R_0 = 5\ \text{cm.} \end{aligned}$$

At any intermediate point between entry and the point of arrest where the residual range is R cm., the root-mean-square lateral deviation $D_{\perp\ \text{proj}}(R)$ is given by:

$$D_{\perp\ \text{proj.}}(R) = D_{\perp\ \text{proj.}}\left[14{\cdot}9\left(\frac{R}{R_0}\right)^{1{\cdot}81} - 11{\cdot}5\left(\frac{R}{R_0}\right)^{2} - 4{\cdot}4\frac{R}{R_0} + 1\right]^{1/2}\ \text{cm.}$$

which may be approximated by:

$$\begin{aligned} D_{\perp\ \text{proj.}}(R) &= D_{\perp\ \text{proj.}}[1 - R/R_0]^2\ \text{cm.}, && R < R_0/2 \\ &= \frac{D_{\perp\ \text{proj.}}}{\sqrt{2}}[1 - R/R_0]^{3/2}\ \text{cm.}, && R > R_0/2 \end{aligned}$$

(*b*) *Longitudinal spread* (*straggling*) *of homogeneous beam*. The projections of the end-points of the pion tracks along the axis of the pencil are also spread out, due to statistical fluctuations in the energy loss. This distribution is again practically Gaussian. The root-mean-square value of this straggling about the mean range R_0 cm. in body tissue is:

$$D_{\parallel\text{RMS}} = 2{\cdot}6 \times 10^{-2} R_0^{0{\cdot}94}\ \text{cm.}$$

or $D_{\parallel}/R \sim 2{\cdot}3$ per cent for values of R_0 between 5 and 10 cm.

This figure for the straggling in range of a homogeneous beam of π^--mesons is probably smaller than one would require. So the longitudinal spread will be determined in practice by the spread in energy of the incoming π^--mesons; this can be adjusted by the movement of slits in the magnetic focusing system that would be employed. To obtain a spread of ± 5 mm. at 10 cm., an energy spread of ± 3 per cent in the incoming beam would be required. Such resolution is readily obtained.

We wish to thank Prof. C. F. Powell for his great interest and encouragement, and for discussions. We are also indebted to Mr. H. F. Freundlich for several discussions, and for Fig. 2 of this article. After preparing this report, we were informed by Dr. R. D. Hill, of the University of Illinois, that he had considered the problem previously (1958) and had circulated his conclusions in a private letter to certain medical authorities in the United States. These conclusions were somewhat different from those presented here, and the advantages of pion beams over existing beams of protons and γ-rays were not considered sufficiently substantial to warrant further pursuit of the matter.

THE PERCEPTION OF SPEECH

THE growth of communication in the modern world has added a new dimension to applied psychology. In the air traffic control tower, the police information room, or the telephone switchboard of a large concern, men are daily subjected to a barrage of spoken messages with which they are expected to deal speedily and efficiently. In some of these situations, at least, human error can prove disastrous. It is therefore of obvious importance to ascertain the extent to which the human operator can handle a plurality of speech messages, and the factors which dispose him to error. What, in short, are the limits of the human operator conceived as a receiver and transmitter of spoken information?

This question was the theme of a Friday evening Discourse at the Royal Institution on November 18, delivered by Mr. D. E. Broadbent, director of the Medical Research Council's Applied Psychology Research Unit at Cambridge. Although taking the predicament of the air traffic controller as his point of departure, Mr. Broadbent was clearly more concerned with the theoretical upshot of recent work than with its contribution to immediate ends. He directed particular attention to the perception of simultaneous, or nearly simultaneous, messages, to which much research has been devoted during the past ten years. It is now clear that the familiar difficulty in 'hearing two things at once' cannot be ascribed primarily to masking or related interference at the physiological level, and seems due rather to difficulty in allocating the individual words heard to their respective contexts, that is, to perceptual confusion[1]. This difficulty, as Mr. Broadbent pointed out, may be appreciably reduced if the two messages differ in salient characteristics; for example, if spoken in different voices or appearing to originate from different points in space[2]. Indeed, spatial separation has been shown to be particularly effective in reducing error, more especially under conditions in which some of the information is irrelevant to the purposes of the listener[3]. Effective, too, is probability of message in the sense of the communications engineer. The extent to which different messages can be handled at the same time appears to depend not so much on the number of words reaching the two ears as upon the probability of each message. Indeed, two highly probable signals may in fact be perceived simultaneously. In general, Mr. Broadbent is on strong ground in advocating the view that the human brain, in virtue perhaps of its limited size, possesses a limited capacity for the processing of information.

A closely related problem is dichotic listening, that is, the perception of speech fed by independent channels to the two ears. Some years ago, Prof. Colin Cherry was able to show that the effects of feeding two different messages simultaneously, one to each ear, are entirely different from those that are obtained if the same messages are 'mixed' on a tape recording and the two ears stimulated identically[4]. In the case of the independent messages, the observer has no difficulty in listening to one or other message at will or in repeating it concurrently. He can, however, repeat virtually nothing of the 'rejected' message beyond perhaps the sex of the speaker. Yet this 'rejection' is not quite absolute: individual words arriving at the 'rejected' ear may sometimes be heard; for example, the listener's own name[5] or a word fitting more appropriately into the context of the message to which attention is being paid than that actually arriving at the 'accepted' ear[6]. There is evidence, moreover, of short-term 'storage' of the 'rejected' information. In earlier experiments, Mr. Broadbent demonstrated that if a short series of digit pairs was given dichotically, these digits could be correctly recalled, though not in their order of arrival. Almost invariably, the subject repeated first the digits fed to one ear and then those fed to the other[7]. More recent work has, however, suggested that this kind of selection is not governed exclusively by the ear to which attention is given. For example, if three monosyllabic words forming a short sentence are fed simultaneously with three digits such that words and digits alternate at the two ears, subjects are found to repeat first the sentence and then the number, or *vice versa*[8]. It seems possible, then, to listen for words as opposed to numbers just as one can listen to one ear as opposed to the other. At the same time, the existence of obvious differences between these two kinds of selection might suggest that they are governed by different types of cerebral mechanism.

Although few of the phenomena of speech perception find ready explanation in neurological terms, Mr. Broadbent argued in his discourse that the issues which they raise have an important bearing on auditory theory. For example, a vowel sound contains several different components at widely different frequencies, and to identify it requires that one should pick out the several components and treat them as pertaining to the same voice rather than the background noise. How does the auditory mechanism effect this discrimination? Although no very complete answer can be given, Mr. Broadbent suggested that amplitude modulation may play an important part. If a tuned system is subjected to amplitude modulation, the pitch of the resulting sound will, in appropriate conditions, correspond not to that of a steady wave having the frequency of the system but to that of the imposed pulses. In the case of the ear, one may argue that the pitch of a sound will depend not so much on the precise receptors stimulated (as traditional theory holds) as on some feature of the message travelling up the nerve fibres and affected by the rate of amplitude modulation. A likely candidate, Mr. Broadbent suggests, is the frequency of impulses in the auditory nerve. Although no direct neurophysiological evidence is available, Mr. Broadbent argues that experiments with 'synthetic speech' in which different parts of the spectrum can be modulated at different rates are well adapted to test this theory.

The study of speech perception and related problems is advancing with encouraging rapidity. Although the point of view of the applied psychologist influenced by communications theory is not always easy to reconcile with that of the sensory physiologist, the approach outlined by Mr. Broadbent has certainly served to throw valuable light on the limits of the auditory mechanism and on the selective processes which operate in the perception of speech. It may be hoped that the next step will be the translation of the models derived from information theory—which Mr. Broadbent has himself done much to develop—into those of neurophysiology. This possibility one recent writer at least regards as a great deal less remote than is commonly supposed[9].

OBITUARY

Prof. H. T. S. Britton

PROF. HUBERT THOMAS STANLEY BRITTON died after a short illness on December 30; he is survived by his son and daughter. Born at Kingswood on April 22, 1892, he was educated in Bristol at St. George's Grammar School, the Merchant Venturers' College and the University of Bristol, graduating thence in 1914. He spent a short period as a grammar school master and then served during 1916–20 as chemist in the Aeronautics Inspection Department, and during 1920–25 as assistant lecturer at King's College, London. Between 1925 and 1927 he held a senior award of the Department of Scientific and Industrial Research at the Imperial College of Science and Technology, London, and then, after a year or so as lecturer at Norwood Technical College, he commenced his long association with the then University College of Exeter, first as lecturer and then, from 1935 until his retirement, as professor.

Despite a very heavy load of teaching—in the early years he was responsible for the whole of the honours teaching in physical and inorganic chemistry—Prof. Britton was extremely active in research, publishing numerous papers and directing the work of a considerable number of research students. Beyond the confines of his Department he was a prominent figure on the Senate, served at some time on the councils of the Chemical Society, the Royal

Institute of Chemistry and the Society of Chemical Industry, was for a period chairman of the board of governors of the North Devon Technical College, and was a popular extra-mural lecturer. He was instrumental in securing the establishment of the local sections of the Royal Institute of Chemistry and of the Society of Chemical Industry, and played a leading part in the preparations for the elevation of the College to university status.

Britton's research interests lay in the physico-chemical investigation of inorganic reactions in solution, mainly by measurements of the potentials of electrolytic cells incorporating hydrogen, glass and metal electrodes, but also including electrical conductance, diffusion and dialysis, phase-rule studies and polarimetry. He accumulated a mass of quantitative data relating to the precipitation of hydroxides, hydrated oxides and basic salts of numerous metals, and to the formation of complex ions involving a variety of acids and bases; he made notable contributions to the 'solution' chemistry of less-common elements such as vanadium, molybdenum and ruthenium, and with Robinson devised the well-known 'universal buffer mixture' which bears their names. Britton's *Hydrogen Ions*, which ran to four editions, is an indispensable reference book in every laboratory concerned with the physico-chemical behaviour of solutions of electrolytes.

Britton was the most approachable of men, ever warm-hearted and friendly, and was extremely popular with his students. He was a lively and entertaining lecturer whether to undergraduates or to an extra-mural audience in the heart of rural Devon, and he retained to the end something of the sceptic and the rebel. As head of department, he made himself freely accessible at all times to staff and students alike, and to colleagues from other departments. On his retirement in 1957 he was made emeritus professor, but his life in retirement was clouded by anxiety over his wife's failing health, and, in June 1959, her death.

Britton will live long in the affectionate memories of the many students who passed through his hands. His writings and researches contributed much to the chemistry of ionic solutions, and he laid the secure foundations on which the future development and expansion of the Chemistry Department at Exeter may confidently be based. S. J. GREGG

NEWS and VIEWS

The Space Vehicle 1961γ

A HEAVY Earth satellite was projected into orbit from a launching point in the U.S.S.R., probably at a time near midnight on February 11–12, and early on February 12 a space vehicle was launched from the heavy satellite, with the aid of a rocket which accelerated it to a speed greater than the escape speed of 11 km./sec. This space vehicle, which weighs 643·5 kgm. (1,419 lb.), was directed along a flight path designed to take it into the vicinity of the planet Venus, which it is expected to reach in the second half of May 1961, when the planet will be about 70 million km. from the Earth. At 9 hr. U.T. on February 12, the space vehicle was stated to be 126,300 km. from the Earth's surface at longitude 86° 40′ E. and latitude 6° 04′ N.; 24 hr. later, the distance had increased to 489,000 km., at longitude 88° 2′ E. and latitude 0° 53′ N. The vehicle's radio transmitter operates, on command, at a frequency of 922·8 Mc./s., and is to be switched on every 5 days. It is powered by chemical batteries, and these are re-charged by solar cells, which are orientated towards the Sun. The main purposes of the vehicle are to test the procedures for launching bodies into interplanetary orbits, to test guidance systems and communication at extreme distances, to investigate the size of the solar system, and to measure various physical properties of interplanetary space.

This vehicle, by far the heaviest yet launched into interplanetary space, represents a substantial step forward in space technology. Its flight was preceded by the launching of the heaviest Earth satellite, 1961β, weighing 6,483 kgm., which was put into a close orbit on February 4, and apparently served as a test vehicle for 1961γ. Any physical measurements made by the space vehicle in the neighbourhood of Venus will add to our scanty knowledge of this inscrutable planet; but it has not been disclosed whether the vehicle carries the terminal guidance which would be needed to make a very close approach to the planet.

The Science Museum Library: Mr. J. A. Chaldecott

MR. J. A. CHALDECOTT has been appointed keeper of the Science Museum Library in succession to the late Mr. H. T. Pledge. Mr. Chaldecott, who has been secretary to the Advisory Council of the Science Museum and deputy keeper in the Department of Physics since February 1957, was educated at Latymer Upper School, Hammersmith, and at Brentwood School. He read physics and mathematics at Borough Road College, graduating at the University of London in 1938. Early the following year he was commissioned in the Meteorological Branch of the Royal Air Force Voluntary Reserve; for much of the Second World War he was seconded to army formations, and his services earned him mention in dispatches. After the War he read history and philosophy of science at University College, London, obtaining his M.Sc. in 1949. He was lecturer in physics at Acton Technical College for a short period before entering the Science Museum, in 1949, as an assistant keeper. He catalogued the George III collection of scientific instruments, the heat and thermal instruments collection, and also edited the commemorative volume *The Science Museum: the First Hundred Years*. His published papers have been in the history of physics. He is a member of Council of the British Society for the History of Science.

Ministry of Aviation: Mr. F. H. Scrimshaw

MR. F. H. SCRIMSHAW has been promoted to the rank of deputy chief scientific officer. In 1939 Mr. Scrimshaw graduated in physics at the University of London with honours and was awarded the Granville research studentship as the best University of London physics graduate of the year. His first work at the Royal Aircraft Establishment, which he joined in 1939, was concerned with bomb-sights, followed by a spell during 1942–45 of research on airborne automatic dead-reckoning navigation equipment. On the formation of the Blind Landing Experimental Unit at Martlesham in 1945, Mr. Scrimshaw took charge of the flight control section which investigated such problems as the use of automatic pilots, leader cable guidance and automatic throttle control to aircraft landings. This work has come to fruition recently in the British Auto-land system which Britain is now actively sponsoring for use by civil airlines. In 1950 Mr. Scrimshaw returned to the Royal Aircraft Establishment, where he continued to work on inertia navigation systems, becoming an acknowledged expert in this field. He continued this work until 1958, when he became director of scientific research (electronics) at headquarters of the Ministry of Aviation. In this post Mr. Scrimshaw has been associated with long-term research projects in electronics in which the Ministry of Aviation has been engaged.

Anatomy at Cardiff: Prof. J. D. Lever

Dr. Jeffrey D. Lever has been appointed, in succession to the late Prof. J. S. Baxter, to the chair of anatomy in the University College of South Wales and Monmouthshire, Cardiff. Dr. Lever was educated at Westminster School and at Trinity College, Cambridge, which he joined as an Exhibitioner in 1941. He graduated in medicine in 1946, having pursued his clinical studies in St. Thomas's Hospital. After service in the Navy he joined the academic staff of the Anatomy Department in Cambridge as a University demonstrator. He was awarded the M.D. degree in 1954, and, in 1955, was appointed to a lectureship. During the academic year 1954–55 he was visiting instructor and research assistant in the Department of Anatomy, Washington University, St. Louis, where, under the direction of Dr. E. W. Dempsey, he received a training in electron microscopy. His interests as a research worker are concerned largely with the functional histology and fine structure of the endocrine glands. His publications include contributions on the adrenal gland, the islets of Langerhans, the parathyroids, and the carotid body. In 1956, on the recommendation of the Anatomical Society, he was awarded the Symington Prize, for original work in anatomy, by the Senate of The Queen's University of Belfast. He was elected to a fellowship of Trinity College, Cambridge, in 1957, and since then has been director of medical studies in the College. He is a member of the Council of the Anatomical Society.

A Co-operative Space Research Programme

Replying to a request in the House of Commons for a statement on progress achieved towards a Commonwealth and European space research programme, the Minister of Aviation, Mr. Peter Thorneycroft, said that at the Strasbourg Conference delegates had expressed keen interest in the political, scientific, economic and technological advantages of co-operation in the manufacture of launchers for heavy satellites. If an organization for this purpose was set up, it would be on a long-term basis, and could as its first programme use the British *Blue Streak* as a first stage, a French rocket as a second stage, and a third stage manufactured elsewhere in Europe. The United Kingdom and French Governments would now be asking their partners in the Conference to study its results with the view of deciding whether to form such an organization. The Federal Republic of West Germany was in principle to take part, but had neither the possibility of, nor the interest in, developing a rocket of its own for space purposes. As to co-operation with other countries, Mr. Thorneycroft said that Australia would undoubtedly be the place from which this programme, using *Blue Streak* as a first stage, would be launched, and we would, of course, welcome every co-operation with the United States. The British subscription would be on the basis of 33⅓ per cent which, on the estimated cost of £70 million, would be £23,300,000 over five years.

The Cotton, Silk and Man-made Fibres Research Association

In a written answer in the House of Commons on February 9, the Minister of Education, Sir David Eccles, as representing the Minister for Science, stated that it is proposed that the merger of the British Cotton Industry Research Association and the British Rayon Research Association into one association, to be called the Cotton, Silk and Man-made Fibres Research Association, will be effective from April 1, 1961. The annual expenditure will rise from about £490,000 to about £580,000 over the next five years, the industrial income being sought mainly from processors of cotton and man-made fibres by statutory levy under the Industrial Organization and Development Act, together with support from producers of man-made fibres. The new Research Association would occupy the present site of the Cotton Research Association at Didsbury, where the laboratories will be extended, and the laboratories of the Rayon Research Association at Heald Green will be sold. The research staff of the new Association will be drawn from the existing Associations, with adequate provision for redundancy, including retirement pensions, compensation and placing staff in other employment.

Committee on Higher Education in Britain

The Prime Minister announced, on December 20, that Lord Robbins would be chairman of the committee to consider higher education in Britain, and the terms of reference of the committee were announced (see *Nature*, February 11, p. 427).

The members of the committee have now been announced. They are: Sir David Anderson, formerly director of the Royal College of Science and Technology, Glasgow; Dame Kitty Anderson, headmistress, North London Collegiate School; Mr. A. Chenevix-Trench, headmaster, Bradfield College, Berkshire; Prof. J. M. Drever, professor of psychology and lately dean of the Faculty of Arts, Edinburgh; Mr. A. L. Elvin, director of the University of London Institute of Education; Miss Helen Gardner, professorial fellow, St. Hilda's College, Oxford; Sir Edward Herbert, an engineer, chairman of the governing body of Loughborough College of Technology and member of the Court of the University of Nottingham; Sir Patrick Linstead, rector of the Imperial College of Science and Technology, London; Sir Philip Morris, vice-chancellor of the University of Bristol; Mr. H. C. Shearman, vice-president of the Workers' Educational Association; Mr. R. B. Southall, general manager of the Llandarcy (BP) refinery, Swansea.

Research Expenditure on Fisheries

THE report of the committee of inquiry into the fishing industry, of which Lord Fleck was chairman, laid emphasis on adequate finance being available for scientific and industrial research bearing on the industry. In moving the second reading of the White Fish and Herring Industries Bill in the House of Commons on January 31, the Minister of Agriculture, Fisheries and Food, Mr. C. Soames, said that the Bill was not prompted by the Fleck report, to implement which would require major legislation and detailed consultation before such legislation could be drafted; and the importance of research for the fishing industry was stressed. Mr. J. H. Hoy suggested that if the normal fishing grounds were contracted, research directed towards the discovery of new fishing grounds should be undertaken; and Capt. M. Hewitson inquired specifically whether the possibility of fishing grounds off the coast of Ghana had been investigated. He thought the prospects of industrial fishing in that area were unlimited. Sir William Duthie also strongly urged adequate research to remove as much guesswork as possible from fishing, particularly as regards the incidence of shoal migration, and suggested that in this way we could find the answer to the depletion of the herring shoals in the North Sea. Other speakers agreed that, as the Fleck Committee pointed out, the fishing industry in many aspects lags behind other industries in the adoption of modern equipment, methods and organization; but it is also recognized that the question of research is closely linked with the economic aspects, since the application of its results increasingly involved large capital expenditure, beyond the resources of the small owner.

Mr. H. Hughes, who quoted the estimated figure of £1 million for expenditure by Britain on fisheries research in 1959–60, with a further £250,000 for research into handling and processing fish, referred also to the view of the Fleck Committee that a much more intensive research effort could profitably be directed towards exploiting more effectively the resources of the sea, and that to keep pace with changing conditions, the industry should devote a substantially greater sum to the development of improved catching and processing techniques. Questions raised in the debate relating to the closing of one of the three research stations at Aberdeen led the Secretary of State for Scotland, Mr. J. S. Maclay, to be at some pains to explain that the station which had been sold to Unilever, Ltd., which would continue research there, was the Ministry of Agriculture, Fisheries and Food Experimental Food Station, which was not primarily a fishing research station. The Marine Life Laboratory of the Department of Agriculture and Fisheries for Scotland, adjacent to the Department of Scientific and Industrial Research's research station at Torry, are both continuing and cover research into fish and the sea, biology, hydrography and the abundance and distribution of commercial fish stocks.

Telephone Services in Britain

IN opening a debate in the House of Lords on February 11 on the Post Office Telephone Service, prompted by the White Paper (Cmnd. 973) on *Post Office Capital Expenditure*, 1960–61, Lord Crook said that there are at least six main reasons why a steady figure for capital investment is essential for the telephone service. One of these is a steady research programme, and this is closely related both to the telecommunications industry and to the growth of electronics in the world of the telephone, where, Lord Crook believes, Britain is in danger of losing a great market. He questioned whether the Dollis Hill Experimental Establishment has been allowed to get ahead fast enough and given sufficient opportunity and finance. It is important, he said, to realize that the telephone service earns money, internally in industry within Britain, and also in respect of exports. The Earl of Listowel, supporting much that Lord Crook had said, added that the telephone service in Britain is backward because we have not put sufficient capital into the manufacture of telephone equipment and have not ensured for the Post Office the normal programme of capital development that any large business enterprise requires.

Replying for the Government on the debate, Lord St. Oswald assured the House that no limitation has been placed on research for electronic exchanges because of shortage of capital investment. It has been deliberately decided to employ different techniques in different functional sections of the experimental exchange at Highgate Wood, so that their merits can be compared from all points of view; the ultimate aim is an economic standard electronic exchange. Lord St. Oswald claimed that work is proceeding at high pressure to produce improved designs, so that British industry can retain its position in the forefront of telecommunication development and be able to offer in world markets electronic exchanges fully competitive with those of any other manufacturers. He pointed out, however, that development is not solely for export, and a besetting problem generally is the comparative lack of enthusiasm among telephone subscribers for anything new. The average residential telephone user makes less than one call a day on his instrument, and even putting business and residential subscribers together, the average is only 530 a year, compared with between 1,000 and 2,000 in Sweden, Canada and the United States. The Post Office, in conjunction with the University of London, has recently instituted a joint research programme into the sociology of telephone usage.

Research on Mental Hea'th in Britain

THE Minister of Health, Mr. E. Powell, in a written answer in the House of Commons on February 8, stated that after completing its full-scale review of mental health research early in 1959, the Medical Research Council established a new committee on clinical psychiatry, under Sir George Pickering as chairman, and one on the epidemiology of mental disorders, with Sir Aubrey Lewis as chairman. Each committee has appointed working parties to study special aspects of its field, such as the psychopathic personality, the value of drugs in psychiatry as assessed by clinical trials, and the use of national statistics of mental disorders. Of the total funds available to the Council for the past five years, the percentage spent on mental health research was as follows: 1956–57, 2·3; 1957–58, 1·8; 1958–59, 3·8; 1959–60, 4·4; 1960–61, 4·7.

Rostherne Mere, Cheshire, as a Nature Reserve

ROSTHERNE MERE and some surrounding woodland in north Cheshire have been presented to the Nature

Conservancy by the executors of the late Lord Egerton of Tatton, in accordance with his wishes. The area is to be declared a National Nature Reserve. Thousands of ducks which have learned to rely on the Mere as a sanctuary will thus continue to have the strict protection given during Lord Egerton's lifetime. The neighbouring Tatton Park, with its meres, having already been handed over to the National Trust and the Cheshire County Council, will provide for the recreational needs of the public. The area given to the Conservancy consists of 195 acres, and a nature reserve agreement with the new owner and the farmers of land immediately overlooking the Mere will cover an additional 183 acres. The hydro-biology of the area is of great interest and its supreme value as a winter resort for wildfowl, as well as a breeding-place for certain aquatic birds, is partly due to the strict control over access and disturbance maintained by the late Lord Egerton. In spring and autumn many migrant birds may be seen there resting on passage, and some rare species have been recorded. The late A. W. Boyd carried out numerous and detailed observations there for at least forty years and his work has made a great contribution to our knowledge of its bird fauna, which his friends hope to commemorate by building an observation post overlooking the Mere.

Peak District National Park

The third of the official guide books to Britain's National Parks has been prepared by the Peak Park Planning Board in association with the National Parks Commission, under the editorship of Patrick Monkhouse (*National Park Guides*, No. 3: Peak District. Pp. viii+90+26 plates. London: H.M. Stationery Office, 1960. 5*s*. net). Among the authoritative contributors is Lt.-Col. Gerald Haythornthwaite, who deals with the building traditions to be found in the Peak. Other contributions describe the geological structure and scenery of this National Park, its animal and plant life, and the marks made by man's occupation of the land since early times. There are also chapters on farming and industry in the Park to-day, as well as an account of the work done by the Peak Park Planning Board in preserving the beauty of the varied landscape and promoting its enjoyment. That the facilities of the Park are appreciated is shown by the way natives of grim industrial areas like South Lancashire, North Staffordshire and Sheffield seek solace in its open spaces. The guide book contains a gazetteer of places of interest which would be especially appreciated by visitors.

Changes in Sea-Level recorded in New Zealand

Hutton's doctrine that the present is the key to the past has been taken increasingly to heart by geologists in recent years. The sedimentary processes operating on the continental shelves and in various intertidal environments have received widespread attention since the War. Before older sedimentary rocks can be interpreted in terms of the Holocene, however, it is necessary to allow for any deviations from the norm which may have resulted from the Pleistocene glaciation. In particular, small changes in sea-level can influence sedimentation profoundly, and it is essential to determine any changes that have occurred as accurately as possible. Further evidence concerning world-wide fluctuations has recently been brought to light. In northern North Island, New Zealand, J. C. Schofield (*N.Z. J. Geol. and Geophys.*, **3**, 467; 1960) has been able to trace a number of elevated chenier ridges and to date the origin of several by radiocarbon determinations on shells. The area is believed to have been tectonically stable since the end of the Miocene period, so that the levels of the ridges may be interpreted in terms of changes in sea-level. Neglecting minor changes, the sea-level appears to have fallen 7 ft. from about 2000 B.C. to the beginning of the Christian era, and to have remained relatively stable since then. The changes correlate favourably with transgressional periods recorded in Europe. The present rise of 8–9 in. a century may well be only a minor fluctuation in what is now an essentially stable ocean-level.

Hatfield Technical College

As from September next Hatfield Technical College will be renamed Hatfield College of Technology. Three departments of engineering have recently been formed, namely: the Department of Mechanical and Aeronautical Engineering (head of department, D. R. Samson); the Department of Industrial Engineering (head of department, J. D. Smith); the Department of Electrical Engineering (head of department, B. F. Gray). It is also announced that Dr. R. F. Robbins has succeeded Dr. Fred. Lester as head of the Department of Science.

The Institute of Metals

The Council of the Institute of Metals has made the following awards of medals for 1961: *Institute of Metals (Platinum) Medal*, to Major C. J. P. Ball, chairman of Magnesium Elektron, Ltd., in recognition of his outstanding services to the non-ferrous metal industries and, in particular, to the magnesium industry; *Rosenhain Medal*, to Dr. P. B. Hirsch, of the Cavendish Laboratory, Cambridge, in recognition of his outstanding contributions in the fields of physical metallurgy and metal physics.

The following have been elected officers and members of the Council of the Institute of Metals: *president*, Prof. H. O'Neill (head of the Department of Metallurgy, University College of Swansea, University of Wales); *past-president*, Sir Ronald Prain (chairman and president, Rhodesian Selection Trust, Ltd.); *vice-presidents*, Mr. W. F. Randall (deputy chairman and managing director, Telcon Metals, Ltd.) and The Right Hon. The Earl of Verulam (chairman, Enfield Rolling Mills, Ltd.); *ordinary members of Council*, Mr. N. I. Bond-Williams (managing director, the Aston Chain and Hook Co., Ltd.); Prof. A. H. Cottrell (Goldsmiths' professor of metallurgy, University of Cambridge); and Mr. G. A. Rider (deputy managing director, Birmid Industries, Ltd.).

University News: Birmingham

The Ford Foundation has given the University a grant of 440,000 dollars to support a programme of research extending over the next fifteen years in the Department of Anatomy into the reproductive physiology of monkeys. The Department has been made the recipient of this benefaction because, under the direction of Sir Solly Zuckerman, work of this nature has been one of its main interests for many years.

London

THE following titles in respect of the posts occupied have been conferred: Sir William Collins professor of anatomy in the University on Mr. G. W. Causey (Institute of Basic Medical Sciences); reader in veterinary physiology on Dr. F. R. Bell (Royal Veterinary College); reader in anatomy on Dr. A. S. Breathnach (St. Mary's Hospital Medical School); reader in geography on Dr. E. H. Brown (University College); reader in clinical rheology on Mr. D. G. Melrose (Postgraduate Medical School of London); reader in chemical engineering on Dr. J. W. Mullin (University College).

Southampton

SIR BASIL SCHONLAND, director of the Atomic Energy Research Group, Harwell, has been elected junior pro-chancellor in succession to the late Sir Henry Tizard.

"Fatigue Straining of Copper Whisker"

DR. EDWARD EISNER has written with reference to the communication in *Nature*, 188, 1183 (1960) directing attention to some misprints. "The units of stress in paragraph 1 should be kgm./mm.^{2}. The second sentence of paragraph 3 should contain the phrase '. . . with the whisker encastered in diphenyl carbazide glass . . . ' instead of the present phrase. This is intended to convey that a part of the whisker at one end was embedded in the glass, so that that portion of the whisker was rigidly held, approximately normally to the surface of the glass. The second part of the last sentence of paragraph 7 should read, ' . . . it afterwards withstood 10^6 cycles at 0–1·1 per cent and 10^6 cycles at 0–1·7 per cent strain, and it kinked after 10^5 cycles at 0–2·3 per cent strain'. "

Announcements

MR. DENZIL FREETH, member of Parliament for Basingstoke, has been appointed Parliamentary Secretary to the Minister for Science, and will answer in the House of Commons for the Lord President of the Council and the Minister for Science.

SIR EDWARD APPLETON has been awarded the Gunning Victoria Jubilee Prize for the period 1956–60 of the Royal Society of Edinburgh for his distinguished contributions to ionospheric and radio physics.

MR. BRIAN G. ROBBINS, secretary of the Institution of Mechanical Engineers, is to retire on June 1 and will be succeeded by Mr. Kenneth H. Platt, at present deputy secretary of the Institution. Mr. Platt, who is a graduate of the University of Glasgow, has been associated with engineering education and training, both in industry and with the Ministry of Education.

THE French Government is offering again this year scholarships for further study or research in France. The grants will be given for periods of 3–10 months during the academic year 1961–62. Candidates should hold a degree or equivalent qualification. Applications from graduates in science or medicine will be particularly welcome. Application forms and further information can be obtained from the Scientific Office, French Embassy, 22 Wilton Crescent, London, S.W.1. The closing date for application is March 16.

THE Trustees of the Ramsay Memorial Fellowships Trust will consider in June applications for a Ramsay Memorial Fellowship for advanced students of chemistry. The value of the fellowship will be £700 per annum, to which may be added a grant for expenses of research not exceeding £100 per annum, and it will normally be tenable for two years. Completed application forms must be received by the Joint Honorary Secretaries, Ramsay Memorial Fellowships Trust, University College London, Gower Street, London, W.C.1, not later than April 17.

THE Institute of Physics and the Physical Society is arranging a conference on "Palæomagnetism", to be held at King's College, University of Durham, Newcastle upon Tyne, during April 20–22. Further information can be obtained from the Administrative Assistant, Physics Department, King's College, Newcastle upon Tyne.

AN international symposium, entitled "Host Tumour Interactions", is to be held at the Henry Ford Hospital in Detroit, Michigan, during May 18–20. Further information can be obtained from Dr. Michael J. Brennan, Oncology Division, Secretary, Symposium on Host Tumour Interactions, Henry Ford Hospital, Detroit 2, Michigan.

THE Unesco South Asia Science Co-operation Office is organizing a regional seminar on "Scientific Documentation", during March 7–16, at the Indian National Scientific Documentation Centre, National Physical Laboratory, Hillside Road, New Delhi. Further information can be obtained from Unesco South Asia Science Co-operation Office, 21 Curzon Road, New Delhi.

THE Council for British Archæology is organizing a conference on "Prospecting in Archæology by Geophysical Methods" in collaboration with Dr. J. C. Belshé, Department of Geodesy and Geophysics, University of Cambridge. The conference will be held in the Institute of Archæology, 31–34 Gordon Square, London, W.C.1, during March 4–5. Further information can be obtained from the Council for British Archæology, 10 Bolton Gardens, London, S.W.5.

A DISCUSSION conference on "Science and Education" is being arranged by the Association of Scientific Workers, Association of Teachers in Technical Institutions, Association of University Teachers, National Union of Teachers and Science Masters' Association, and will be held at the Mahatma Gandhi Hall in London on March 11. Correspondence in connexion with the conference should be addressed to the Conference Secretary, c/o Association of Scientific Workers, 15 Half Moon Street, London, W.1.

A ONE-DAY symposium on "Computers for the Chemical Engineer" is to be held in the University of Birmingham on March 28. It is being organized by the Graduate Section of the Birmingham University Chemical Engineering Society and the Graduates and Students Section of the Institution of Chemical Engineers, Midlands Centre. Further information can be obtained from the Registration Secretary, Department of Chemical Engineering, University, Edgbaston, Birmingham, 15.

WRITING with reference to the communication entitled "Spontaneous Cytomegalic Inclusion Body Disease involving Lacrimal Glands of Caesarian-derived (so-called) Pathogen-free Rats", in *Nature*, 188, 506 (1960), Dr. Hans Meier states the animals used were not ". . . raised in the Roscoe B. Jackson Laboratory", but in the laboratories of the Children's Cancer Research Foundation, Boston, where the work was carried out

THE 1961 EXHIBITION OF THE INSTITUTE OF PHYSICS AND THE PHYSICAL SOCIETY

THE forty-fifth Annual Exhibition of Scientific Instruments and Apparatus held in the Old and New Halls of the Royal Horticultural Society in London during January 16–21 was the first since the amalgamation of the Institute and the Society. By continuing in its established tradition, it has incidentally managed to conform with ancient precedent, for the sixth King James of Scotland also suffered no change of character on becoming the first of a united body. It was propitious that the activities and publications of the Institute and Society were displayed conspicuously on an attractively arranged stand, and many visitors must have been glad of this opportunity to make a closer acquaintance with their host. From the point of view of learning about new developments, it was a very good exhibition. The footnote 'demonstration' in the catalogue usually meant not just that a device would be working, but that an experiment to explain its principle or its uses had been mounted. Things progress so fast nowadays that even the term 'trend' would be out of place (if it has not already been registered to name a detergent, anyway); and the uninitiated can only hope to sense what is more like a rate of increase of acceleration. This seemed steepest in fast-operating elements for computers, instrumentation for thermonuclear research, and micro-wave amplifiers, all directed towards the future; and in physics applied to archæology, using nuclear and other techniques for raking up the past.

Several stands exhibited devices incorporating the new Esaki or 'tunnel' diode, made of germanium antimonide or indium antimonide; this operates by a quantum-mechanical tunnelling across the energy gap at a p–n junction, and its chief virtue is high speed. Its uses in logic and memory circuits and for amplitude–time discrimination were shown. The Royal Radar Establishment illustrated the behaviour of a tunnel diode in a magnetic field, which alters the energy gap and reduces the current. Microminiaturized solid circuits, and also circuits built up from thin films, were displayed. Among new ceramic materials were those designed for capacitors, high-temperature ceramics of the silicon nitride and silicon carbide type, and ceramic elements for electroluminescent panels.

Thin magnetic films, using material of the permalloy type, are made for information storage and millimicrosecond switching elements. Two firms demonstrated apparatus for determining the hysteresis loops of thin films, and for observing the domain boundaries visually by means of the Kerr magneto-optical effect. The General Electric Company showed how the easy direction of magnetization can be determined, and also a device for testing magnetic-film matrix elements under simulated computer conditions.

How to deal with the 14-MeV. neutrons resulting from the (D,T) reaction is one of the problems of the thermonuclear investigators, and three neutron generators producing 14-MeV. neutrons by bombarding tritium-containing targets with 100-kV. accelerated deuterons were displayed, for either pulsed or steady operation. These will enable studies of this interesting product of the (D,T) reaction to be made at high flux densities without having to operate *Sceptre* and such-like as sources. Associated Electrical Industries, Ltd., of Aldermaston, showed a data-processing system for thermonuclear research, following the fluctuations of an unstabilized discharge in a glass torus, intended to study what goes on in *Sceptre* itself.

Amplification of various kinds was featured in many exhibits. Five-stage optical image intensifiers, using secondary emission from thin-film dynodes and amplifying up to 100,000 times, represent one aspect; and there were many micro-wave low-noise and other amplifiers. Standard Telephones and Cables, Ltd., illustrated the principle of the parametric amplifier by a mechanical analogue; and there was a parametric amplifier for ultra-high frequencies which operated after frequency conversion down to the X-band. I learned from a physicist working in this field that the maser of the future for satellite and space work is the travelling-wave tube—of the immediate future, that is. Production types of travelling-wave tubes were shown, and the Services Electronics Research Laboratories had a high-power version which operated at about 5 kW. This establishment also had a cyclotron wave-amplifier (Adler tube); and Associated Electrical Industries, Ltd., featured what was called a quadrupole electrostatic cyclotron wave-amplifier, which has not so far reached the stage of being a low-noise device.

Fundamental physics was exhibited in the demonstration arranged by the Atomic Energy Research Establishment of the Mössbauer effect, in which the γ-rays emitted by one transition in an excited iron-57 nucleus are absorbed by a different transition in an iron-57 target moving at a suitable relative velocity, the resonance being displayed on a velocity spectrometer. Among the exhibits from the National Physical Laboratory was a new absolute radiometer, determining radiant power in terms of electrical power. What might almost be called 'unfundamental physics' was shown in a piece of intriguing hydrometry, which used a thin-walled transducer vibrating within a liquid to determine the density of the liquid to better than 1 per cent—valuable for the particular kind of instrumentation that it was aimed to do, of course, but a long way round in principle.

Magnetometry was represented by proton-resonance magnetometers; one by Mullard, Ltd., adapted to control the oscillator at what the description consistently and nostalgically called the "Lamour frequency", and another as part of the comprehensive exhibit of the Research Laboratory for Archæology and the History of Art, Oxford, where one would have liked to spend a good deal longer learning about the highly ingenious stratagems used to detect buried buildings and pottery by measuring the small changes they produce in the ambient magnetic field and its vertical gradient; it was amazing to learn that the real source of this change is in many cases the result of a slight alteration in the magnetic properties of clay produced by firing. The Signals Research and Development Establishment demonstrated a rubidium-vapour magnetometer, which is best described as the optical-pumping (or 'photon-spin-pumping') device working in reverse. The effect of a magnetic field, which separates the otherwise degenerate spin-levels by an extent proportional to this field if it is small, is used to measure the strength of the field. A perpendicular radio-frequency magnetic field is adjusted to the energy difference between the pair of levels which have been population-inverted (that is, to the Larmor frequency when the system starts to operate maser-wise, a state that is detected by the strong absorption of the pumping beam of circularly polarized rubidium D_1 light). Thus, instead of tuning to a given radio-frequency by altering the field, the system is tuned to the ambient field by altering the frequency. This is sufficiently sensitive for geomagnetic observations, and may possibly be applied to aerial and space magnetic surveys; indeed, the actual apparatus was too sensitive to work in the disturbing fields of the Hall, and was planted out on the Westminster School playing-field.

These are the impressions of a day's visit; a proper appreciation would have needed the full five days, and some considerable preparation beforehand. There was much that I missed, and one highlight in the form of a miniature lighthouse with a brilliant source that I even failed to identify properly. The exhibits from various research laboratories of the Department of Scientific and Industrial Research were representative of the wide variety of tasks they undertake. The Science Museum had two exhibits, one ancient and one modern, and there were six contributions from university departments; it would add further facets to a brilliant occasion if we could see, among all the new tools for research and development, more of the new apparatus designed at the universities for their practical classes and demonstrations, and at the Science Museum for the instruction of the general public.

Evening discourses were given during the Exhibition by F. S. Burt, on "Hydrodynamics Research"; by Dr. G. E. R. Deacon, on "The Physics of the Ocean"; and by Dr. F. P. Bowden, on "Some Physical Problems in Travelling at Supersonic Speed".

G. R. NOAKES

CALORIE BALANCE IN MAN

THE one hundred and thirty-seventh meeting of the Nutrition Society was held in the Middlesex Hospital Medical School on December 17, and took the form of a symposium on "Calorie Balance in Man". Perhaps it was optimistic to expect a symposium, continuing from 10.15 a.m. to 4.30 p.m. on the Saturday a week before Christmas, to be popular. In fact, it was a well-attended meeting with an audience of more than 100. The chairman was Sir Charles Dodds.

Not so many years ago the subject of "Calorie Balance" would have been an unlikely topic for such a symposium. Interest in calories, at least in relation to human energy, was at a low ebb scientifically and a rather naive idea was prevalent that little new remained to be discovered in this field. Far from this being the case, a most notable impression gained from the speakers at this symposium was the great dearth of reliable relevant information.

The lack of information and the misconception about many aspects of human energy metabolism were mentioned in relation to some of the "Basic Physiological Factors affecting Calorie Balance", the title of the paper by Dr. J. V. G. A. Durnin (University of Glasgow). Part of the complexity of 'calorie balance' arises because of the difficulty of assessing methodological accuracy; there is no sure way of knowing whether the intake of calories or the expenditure of energy represents the 'normal' or usual state for the individual subject. He, or she, may be eating more or less, during the experimental study, than would normally be the case, or the level of energy expenditure may be altered. Since it is extremely difficult under field conditions to carry out such measurements over a period of more than a few days, theoretically one possible way of finding a departure from the normal would be to measure a change of weight in the subject. Part of this paper and a large part of the discussion were devoted to the balance of weight, and Dr. Durnin showed results for young men, weighed under highly standardized conditions, where their gross body-weight changed by up to 3 lb. (1·4 kgm.) from day to day. Such changes, presumably almost entirely due to alterations in the fluid content of the body, make the weighing of subjects quite worthless in regard to the balance of energy.

Other factors dealt with were exercise (so often discussed emotionally rather than rationally), climate, age (growth in the young and inversion of growth in the old) and the efficiency of utilization of food by the body.

That most of us do not normally attain balance of energy from day to day was shown clearly by an analysis on the results for 69 individuals, where only 4 subjects had a significant correlation between their intake and output of energy; our 'appetite' is a fickle mechanism.

Calorie balance is probably a long-term control, which may be effected by centres in the hypothalamus responding to changes in the fat depots of the body and then influencing the general level of food intake and perhaps even of bodily activity. In this control, the reticular activating system of the brain stem, the limbic system and the hypothalamus may act together. This was suggested by Dr. G. C. Kennedy (University of Cambridge) in his paper "Central Nervous Regulation of Calorie Balance". The importance of exercise was stressed, both in relation to man and to studies on animals; much work on rats or mice is not comparable because of varying levels of physical activity resulting from restrictions imposed by some types of animal cages. Similarities between a 42 stone (267 kgm.) obese patient and experimentally obese rats were shown by both the astonishing hyperphagia and also lack of resentment or discomfort when food was restricted. They were also alike in their inactivity.

It has been the custom, at certain levels of medical therapeutics, to treat obesity as if it were primarily an endocrine disorder and give the patient mixtures of tissue extracts from various endocrine glands.

The traditional blame attached, by many clinicians, to the endocrine system in the causation of obesity was repudiated by Dr. Raymond Greene (London) in "The Effects of the Endocrine System on Calorie Balance in Man". The several endocrine glands were considered in brief, abnormalities of some of them being associated with modifications in the water content of the body; occasionally obesity occurs concomitantly with endocrine pathology but rarely, he thought, is hormonal disorder of any great importance. Dr. Greene suggested that a more interesting discourse, rather than the prescribed one, might have been on "the influence of nutrition on the endocrine system".

Within recent years some changes in outlook on the nature of fat metabolism have been apparent. It has been suggested, although not always with convincing experimental evidence, that the fat depots of the body are far from inactive tissues and indeed are continuously being mobilized. Their nerve supply is stated to be extensive, although most histologists appear to have some difficulty in finding many nerve endings, as opposed to nerve fibres, in adipose tissue. Prof. A. Kekwick and his colleagues have been engaged in studying the "Metabolism of Adipose Tissue", the subject of a paper by Dr. T. M. Chalmers (Middlesex Hospital, London). He suggested that free fatty acid and not glucose might be the principal energy substrate, because of its rapid turnover in the plasma. The fat-mobilizing substance, found in the urine of fasting men, might have some physiological role; its release in the urine apparently depends on carbohydrate metabolism, this being demonstrated in one obese patient treated with equicalorific diets containing varying amounts of carbohydrate.

The second half of the meeting began with a paper on "Energy Expenditure and Calorie Intake in Young Men" by Dr. O. G. Edholm (Medical Research Council, London). In a series of 6 surveys, on 54 Army recruits, he had found variations in energy expenditure of from 2,200 to 6,100 kcalories/day and of intake from 671 to 8,750 kcalories/day, with means of about 3,800. The lack of agreement between calorie balance and the weight balance of the body was again stressed, when these were measured over periods of a few days. There is not sufficient information at present to determine the effect, if any, of severe cold on calorie balance. Work carried out in the Antarctic has shown that men put on weight in the winter and lose weight in the summer; this might be due to climatological factors, but equally well might reflect different social circumstances.

The amount and the rationale of the extra "Calorie Requirements in Pregnancy" were discussed by Dr. A. M. Thomson and Dr. F. Hytten (University of Aberdeen). From a series of several hundred healthy primiparæ studied in Aberdeen, it seemed that an average of about 4 kgm. of fat was added to the mother's tissues by the time pregnancy ended. This is almost certainly physiological, and is required to help the mother in the needs of lactation; however, if breast-feeding is becoming much less common, as appears to be true in Western society, this extra gain in weight may predispose to future obesity. The authors emphasized the small amount of experimental information on the exact increase in food taken during pregnancy and the degree of the changes, if any at all, in the amount of physical activity of the woman; this has a considerable bearing on any extra allowance recommended.

From the interesting paper by Dr. E. M. Widdowson (University of Cambridge) on "Energy Balance in Early Life", new-born babies are frequently subjected to considerable stress by deprivation of food. When this happens, the fat stores of the body are quickly used up, particularly if the baby is required to maintain a high metabolic rate. This will be necessary if the environmental temperature does not fall within the critical range 32-35° C. Babies appear to be as variable in their energy expenditure as adults, and it seems unphysiological to expect all babies to require similar quantities of food.

The discussion of the papers was relevant, interesting and prolonged; the meeting was a most successful one.

J. V. G. A. Durnin

WATER IN AUSTRALIA

MAN'S existence depends on an adequate supply of water, and in Australia, as in few other countries, future development will depend on using water resources to the full. An important step in the utilization of water is the understanding of its properties, and the Victorian Branch of the Royal Australian Chemical Institute found no difficulty in attracting some fifty scientists from four Australian States, whose interests ranged from engineering to biology, to a three-day discussion on this broad topic. The meeting was held at Warburton, Victoria, in late November.

In the opening talk Dr. J. A. Barker reviewed the structure of hydrates and of ice as an introduction to the loosely packed structure of liquid water in which the molecules are prevented from coming into closest proximity by tetrahedrally arranged hydrogen bonds. Each pattern of hydrogen bonds persists for periods of the order of 10^{-12} sec. The theory of Pople, based on this picture, would require each water molecule to have 4 nearest neighbours, 12 next nearest and 36 third nearest, whereas the corresponding figures obtained from analysis of X-ray diffraction data are 4, 11 and 22. Dr. Barker contrasted the anomalous properties of water that result from this structure—the decrease in solubility of gases with increasing temperature, the high negative temperature coefficient of viscosity—with the properties of more normal liquids in which the molecules are closely packed.

Evidence consistent with this structure was presented by Dr. S. D. Hamann, who described some of the effects of pressure on the properties of water and showed how many of the anomalies disappear as the molecules become close-packed at pressures greater than 2,000 atm. Thus with increasing pressure the thermal expansion of water became 'normal', its sound absorption decreased as pressure broke down its structure, and its dielectric constant decreased. Measurements of the conductivity of water under pressures up to 130,000 atm. had produced increases in ionization so that its conductivity equals that of a 5-*N* solution of hydrochloric acid. Pressures of this order are probably reached at depths of 400 km. in the Earth and the enhanced ionization therefore has interesting geophysical implications.

Dr. P. W. Posener showed how microwave spectroscopy could be used to fill in details in the above broad picture.

Considerations of the electronegativity of the oxygen atom in water and hydrates, in both the normal and excited states, led Dr. J. F. Duncan to certain novel and controversial generalizations on the oxidation properties of water. Subjects as diverse as the thermodynamic properties of aqueous ions, the radiolysis of water and the kinetics of aquation reactions could be described semi-quantitatively.

Prof. R. C. L. Bosworth reminded the meeting of the experiments of Nukiyama on the boiling of water, first described in 1934 but disregarded for some fifteen years. A study of boiling produced by a heated platinum wire immersed in water, relating the heat input to the temperature of the wire, revealed three distinct zones of boiling, sometimes with discontinuities between them. The phenomena described by Prof. Bosworth clearly have important practical implications for the design of boilers and heat exchangers. Dr. K. L. Sutherland suggested in discussion that the variation of contact angle with applied potential that had been observed by Frumkin could perhaps be used in controlling boiling. By causing an applied potential to fluctuate at a predetermined rate it might be possible to alternate the periods of bubble formation (large contact angle) with those of bubble release (zero contact angle).

Dr. G. F. Walker described some vermiculite–butyl ammonium ion complexes, their swelling in water, and the intriguing behaviour of their swollen forms. The 10-Å. thick silicate layers, 4 mm.^{2} in area, remained parallel to each other even at interlayer spacings up to 600 Å. The interlayer spacing depended on the concentration and type of cations present and could be varied reversibly under the influence of an electric potential. The phenomenon lacks, as yet, a full theoretical explanation and may have novel applications as a variable molecular sieve.

"Water in Australia" was the topic chosen by Mr. L. R. East in opening the part of the meeting that dealt with conservation. Conservation in Australia poses special problems ; an average rainfall of 16·5 in. compared with the average of 26 in. for all land masses, the large area and small population, and the combined influence of the great variations of rainfall in good and bad years—and of the disastrous reduction of the proportion of rain-water finding its way into the rivers in years of drought. He contrasted the lack of a national water policy in Australia, in spite of significant nineteenth-century contributions, with that initiated in the United States by Theodore Roosevelt in 1901, when he stated that "The reclamation and settlement of arid lands will enrich every portion of our country. . .".

Mr. East discounted the possibility of affecting the climate of neighbouring areas by constructing large inland dams. In this he was supported by Dr. C. H. B. Priestley, who said that, although man had undoubtedly affected weather by his clearing and cultivation of millions of square miles, localized activities were unlikely to have an appreciable effect. He used measurements made over the Mississippi basin to illustrate the balance of water in the atmosphere and showed that up to 90 per cent of the rainfall came from maritime air and only about 10 per cent from continental air.

Mr. E. J. Smith brought the meeting up to date on the progress of rain-making research in Sydney, and pointed out the gaps which exist in the understanding of the nucleation process. In particular, he stressed the possible importance of the particle size of the nuclei as it affected their ability to promote ice-formation and their decay by photolysis and other mechanisms.

Advances in evaporation control with cetyl alcohol were described by Mr. W. W. Mansfield. For large areas of water the alcohol is dusted on to the surface by a grinder-duster, and from the particles a film spreads over the surface. Evaporation, under ideal circumstances, can be reduced by as much as 40 per cent, but the method becomes much less effective as the wind velocity increases. The cost, based on a test at Broken Hill, was one penny per thousand gallons saved.

Two methods of reducing the salt content of water were described by Messrs. R. B. Cooper and L. S. Herbert. Electrodialysis, described by Mr. Cooper, can be used economically to reduce the salt content of water from about 4–5,000 p.p.m. to 3–500 p.p.m. The power needed may be between 9 and 40 kW.hr./1,000 gallons, depending on the salt content and on the flow-rate required. Mr. Herbert discussed some aspects of the distillation of sea-water and suggested possible techniques to improve the efficiency of the process, particularly in increasing heat transfer coefficients. The theoretical minimum energy for any such process is about 3 kW.hr./1,000 gallons, but the practical minimum is about 12 kW.hr./1,000 gallons, a figure which is still far from realization. With known technology it should be possible, on a sufficiently large scale, to produce fresh water for 8*s.* per 1,000 gallons and eventually, with improvements in technique, to reduce this to about 4*s.* per 1,000 gallons.

Mr. J. W. Legge considered the physical-chemical properties of water in relation to the origin and evolution of life, and to L. J. Henderson's views on the fitness of the environment. Knowledge of film stability on natural water surfaces could throw light on current controversy about the kinetics of the synthesis of primitive proteins. He outlined current biochemical views of the splitting of water in photosynthesis and the recombination of hydrogen and oxygen in the aerobic cells.

The movement of water-solute through cell walls was related by Dr. L. R. Finch to the current picture of the membrane. The vesiculation observed in electron micrographs of thin sections, as well as the phenomenon of pinocytosis, involve, of necessity, changes in concentration at the interface. Accelerated metabolism of phospholipids could be shown to take place during such transport processes.

A good deal of discussion followed the contributions of Dr. J. R. Philip and Prof. J. H. Green, which were related to the theory and measurement of ground-water flow. Models for the process are complicated due to changes in the nature of the medium with water content, but Dr. Philip showed how they had been reduced to a tractable form by making use of the basic Navier–Stokes equations. Many were surprised by the high rates of ground-water movement which have been measured by observation of consciously and adventitiously added radioisotopes.

It is pleasing to report on a conference which aroused so much discussion, both formal and less so, and from which so many new patterns of collaboration promise to emerge.

POLITICAL AND ECONOMIC PLANNING IN PAKISTAN

A BROADSHEET recently issued by Political and Economic Planning deals with Pakistan's second Five-year Plan*. After reviewing the first Five-year Plan, it describes briefly the size and objectives of the second Plan and the aims of the various sector programmes, concluding with a brief critique. The fundamental problem for the second Plan is, under severely limiting conditions, to liberate the people from the crushing burden of poverty by ensuring that the rate of growth of the economy exceeds the present 2 per cent annual increase in population. The second Plan, amounting to 1,900 crore rupees, is about 75 per cent larger than the first, a real increase of about 50 per cent, and the methods used are a development of those employed in making the first Plan. Within the various sector programmes, priority is given to schemes already in an advanced state of preparation, or which have already been the subject of foreign government aid; the emphasis is on schemes designed to give quick returns through the better use of existing resources.

Essentially the Plan seeks to make maximum use of the market mechanism, and to employ fiscal and monetary measures rather than direct controls. It adopts a pragmatic approach as between public and private development, with public investment supplementing, rather than displacing, private enterprise, and seeks to develop labour-intensive rather than capital-intensive methods, where a choice is feasible, according to the relative real scarcities of the factors of production. Only a limited call is made on the extra wealth of the community, as the economy progresses, for still further investment, and within the broad priorities of the programmes proposed a substantial element of flexibility has been built into the Plan to meet unforeseeable changes. Of the numerous programmes, those aimed at developing education, health and social welfare services (estimated to cost some 130 crore rupees), like the housing programme, would seem to be out of scale with the needs when judged by contemporary standards and are limited by the resources available. It may be observed that during 1960–65 it is proposed to improve existing social services and to inaugurate schemes for research and training social workers, as well as to attack vigorously such main diseases as malaria, tuberculosis, smallpox and leprosy, to improve greatly the existing schools in East Pakistan, provide more in West Pakistan and extend and improve the universities, as well as extend technical training.

Although the second Plan is regarded as ambitious in the Broadsheet, and requiring devotion, intelligence and hard work if it is to be applied effectively, it is not considered wildly out of scale with the resources, foreign and indigenous, likely to be available. A great effort has been made to improve both the personnel and the systems of administration; a new generation of administrators has been trained and is gradually displacing weak elements from senior positions, while there is some sign that foreign managerial expertize is more warmly welcomed. There is a critical shortage in skilled technicians of all kinds, and a good deal of dilution and improvisation will be needed as well as the full and most effective use of whatever foreign technical services may be available. By and large, it is difficult to find the Plan unsuitable, in any major respect, to Pakistan's needs to-day. There is justification for taking seriously the Government's avowed intention to create a system of democratic government well suited to the conditions of Pakistan. The fact that the second Plan is prepared to tackle the thorny problem of family planning by including a family planning programme of national propaganda, with clinics at all hospitals, dispensaries and maternity centres estimated to cost 3 crore rupees, is regarded as the most hopeful single pointer to the prospect of successful planning in Pakistan.

RADIO RESEARCH DURING 1959

THE report of the Radio Research Board and of the Director of Radio Research for 1959 summarizes the wide range of work carried out at the Radio Research Station, Slough, and at the substation in Singapore*.

The report of the Board refers to the recent revision of the structure and terms of reference of its committees in order to ensure that they adequately cover present and future research activities in the radio-field. Considerable emphasis is laid on the importance of radio in space research, and it is planned that in the immediate future about 50 per cent of the effort at Slough shall be devoted to such research. Details of the research work at the Station during 1959 are given in the report of the Director.

Some preliminary work on data obtained during the International Geophysical Year has been done, and this includes an analysis of data on the incidence, at high-latitude stations, of polar radio 'blackouts' and of polar sporadic-*E* ionization. The results show that these phenomena are produced by solar-particle streams incident on the upper atmosphere along arcs which are similar to the precipitation spirals predicted by Stormer fifty years ago.

A study has also been made of the International Geophysical Year data now available for Slough, Singapore and Ibadan on atmospheric radio-noise. The Slough observations provide detailed information on noise characteristics at four frequencies in the range 20 kc./s.–20 Mc./s. The differences between noise-levels at Slough and Singapore are such as would be expected from known differences in meteorological conditions ; but the noise-level at Singapore is not so intense as might be expected from its close proximity to one of the main thunderstorm areas of the world. Work on atmospherics from local storms is providing information on the power distribution with frequency in the lightning flash, and on the extent to which the wave-forms of the radiated disturbances can be explained in terms of the lightning mechanism.

---

The day-to-day variability in the electron densities of the various ionospheric layers is largely due to the corresponding variability in the wave and particle radiation from the Sun. The derivation of ionospheric indices of solar activity is of special importance for prediction purposes, and the report describes work which has been carried out on such indices for the *E* and *F*2 layers. As part of the International Geophysical Year Calendar Record, *E*-layer solar ionizing radiation indices, *F*2-disturbance indices and polar blackout indices have been calculated for each day of the International Geophysical Year. These daily indices should be invaluable for studies in other International Geophysical Year disciplines.

A rapidly increasing proportion of the activities of the Station at Slough is being devoted to various aspects of space research, and considerable observations have already been made on the direction of arrival of signals from satellites and on the received signal characteristics (Doppler shift, Faraday rotation, telemetry). The station also provides some 100 establishments and observers with predictions, at weekly intervals, of the times and directions of transit of satellites passing within radio-range of observers in the British Isles. Similar work is also being carried out at the Singapore sub-station.

In the radio-measurements and standards field the research and development have been concentrated mainly at frequencies greater than a few hundred megacycles per second. The Station has acted as the co-ordinating centre for the international comparison of milliwatt power-measuring techniques at centimetre wave-lengths, and satisfactory agreement has been found between measurements made with instruments of different types used in the standard laboratories of the United States, Japan and the United Kingdom. Recognition of the possible harmful biological effects of high-intensity electromagnetic radiation at frequencies greater than about 50 Mc./s. has called for the development of reliably calibrated instruments to measure the flux density near high-power transmitters, and the report refers to work being carried out to meet this need.

The study of long-distance ionospheric transmission characteristics, using a sweep-frequency pulse technique, has continued and been extended to a 6,700-km. path between Ascension Island and Slough. It is found that during the daytime the modes of transmission are always very complex because of reflexions from tropical sporadic-*E* ionization, and the sunset deterioration and fading of signals from stations in equatorial latitudes is associated with the break-up of this sporadic ionization at such times. Work on the lateral deviation of signals from Japanese short-wave stations shows that there are often periods when the signals depart significantly from the great-circle path and that propagation by way of auroral reflexion is probably a common feature of night-time propagation over these paths.

Tropospheric radio-wave work includes studies of scatter propagation, delay times on microwave links and the refractive properties of the lower atmosphere. Extensive signal-level, gain in height, fading and diversity measurements have been made over distances from 130 to 400 km. ; but it would appear that no completely satisfactory explanation of troposphere scatter propagation is yet available. The band-widths which can be used in short point-to-point microwave communication links are limited by multi-path propagation, and equipment is being developed at Slough to enable accurate detailed work on the signal-delay times to be measured. The refractive properties of the lower atmosphere are being investigated by means of airborne refractometer measurements, by radar sounding and also by using pressure, temperature and humidity data obtained from a balloon-borne wired-sonde.

Research at the Station on semiconductors has been mainly on transistors and their application. Microwave measurements on certain ferrite–aluminates in a resonant cavity and on transmission phenomena in wave-guides containing these materials has continued.

This 1959 report is of particular interest in that it is the last annual report of Dr. R. L. Smith-Rose, consequent on his retirement from the post in September 1960.

W. J. G. BEYNON

SAFEGUARDING HEALTH IN LONDON

THE annual report on the work of the Scientific Branch, Public Health Department, London County Council, has been prepared by Dr. S. G. Burgers, scientific adviser to the Council*. The Department has 64 members of whom 34 are graduates, and the work covered by them during 1959 varied from routine analysis of foodstuffs—still very necessary—to investigating the properties of cleansing materials used in kitchens and laundries. Much research of a fundamental nature is carried out and opens up many possibilities for economic exploitation. The Council is to be commended for the high quality of the investigations carried out by this section of its staff.

Particularly valuable research was connected with the treatment of sewage. How to produce sulphur from sulphate-enriched sludges was investigated by one team, and valuable information was obtained about the cost and practicability of the process, if conditions of national emergency should render its use necessary. Because of the long duration of these experiments, useful information was also accumulated about the effect of sulphide sludges on metal and other components of the experimental plant. Metals were found to be singularly free from corrosion—stainless steel was as bright after three years exposure as it was initially, mild steel and cast iron (partly protected by calcium carbonate scale) were scarcely affected and steel bolts immersed for eighteen months could be unscrewed with ease. Brass and lead, except for a slight discoloration due to a sulphide film, were almost unaffected, but the zinc coating on the galvanized iron heating coils had completely disappeared, although this may have been due to electrolytes other than sulphides. Rubber was apparently unaffected.

Experiments were also continued on the final disposal of concentrated foam liquids, with particular reference to stripping by means of activated carbon. Aqueous solutions of 1,000 p.p.m. of sodium tetrapropylene benzene sulphonate were passed through a column of 1 in. diam. and 8 in. long, containing 100 gm. of activated carbon. The carbon was soaked in water before use, and care was taken to maintain the liquid level half an inch above the carbon column. During continuous flow the activated charcoal showed almost complete adsorption of the detergent present in the solution in the early part of the test; it was capable of extracting about 90 per cent of the detergent after it had adsorbed 27 per cent of its own weight of surface-active material and could still extract 50 per cent after adsorbing 38 per cent of its own weight. In a later experiment, a solution of 1,000 p.p.m. of sodium tetrapropylene benzene sulphonate in the final effluent from an activated sludge plant was passed through a column containing 100 gm. of activated carbon. A gauze pad was used to intercept suspended solids before the liquid reached the activated carbon in order to avoid choking the interstices in the column. Although adsorption was good, there was evidence that the carbon failed more quickly than when aqueous solutions were used, probably because of adsorption of other constituents of the effluent.

As activated carbon is expensive, attention was given to the possibility of regenerating the material. Attempts to displace the surface-active materials with solvents had only a limited success, and acidification of the dried exhausted carbon, followed by extraction with trichlorethylene, resulted in the removal of only a small proportion of the synthetic detergent in the form of its sulphonic acid.

The most promising method of disposal of condensed foam liquids appeared to be by spraying the foam with surface-activated sludge and allowing the solid content of the material to settle. In the process, the detergent concentration of the supernatant liquor might be expected to be reduced from about 500–600 to 30–40 parts per million, which could easily be treated by admission to primary sedimentation tanks.

Continuing a long-term investigation into the incidence of air pollution, volumetric instruments again indicated a reduction of 7 per cent in the average concentration of smoke in the air of London during the year, and this progressive tendency for improvement has continued since the inception of the Clean Air Act at the beginning of 1957. The sulphur dioxide concentration, for the first time, showed a similar reduction. The improvement was mainly attributable to exceptionally good weather in December, in which the average smoke concentration was only half the usual figure. It is probable that mild weather at the end of the year resulted in reduced domestic coal consumption, and, if this is true, the improvement may not be permanent. It is of interest that during the unusually fine summer the degree of pollution, though naturally low, was very similar to that of the previous cold, wet summer.

A five-month investigation into conditions at Camden Depot was completed, showing that a house adjacent to the railway was subjected to concentrations of black smoke and sulphur dioxide which were on the average 102 and 43 per cent respectively higher than the general London-levels. With the wind in certain directions, the average concentrations rose to at least 200 and 100 per cent respectively above the same London-levels. The situation is expected to improve with the gradual replacement of steam by Diesel locomotives.

RESEARCH IN THE SOCIAL SCIENCES

PRIORITIES for research in the social sciences in industry have been indicated by A. B. Cherns, head of the Human Sciences Section, Department of Scientific and Industrial Research (*Personnel Management*, 42, No. 353; December 1960). In the field of ergonomics, for example, Cherns suggests that the man–machine relationship is a vital aspect of the study of man in industry. The social implications of the man–machine system are such as to justify more attention from social scientists perhaps as members of mixed ergonomic and sociological teams. Ergonomics is a field in which practical applications are easy to appreciate.

The development of adequate criteria of industrial relations should receive a high priority. Have the criteria also to develop indicators? Could the industrialist be advised what chart he should put on his wall to give him a guide to the industrial relations formulated in his plant? Until this be done, the claim to have extracted the full practical value from research cannot be substantiated. A wide comparative study would seem to be required.

The approach of Flanders and others, which aims at developing a study of industrial relations in all its aspects—economic, legal, psychological, sociological and historical—may well provide the stimulation that is needed both to give point to and to encourage wide comparative studies.

There has been an uneasy tug-of-war between interpretations of workshop behaviour based on views of the man in the workshop as an economical and rational animal and those based on views of him as a nexus of social roles—the economic and the sociological points of view. More accurate and systematic observation is a high priority—but not of the extended, reporting type with platitudinous conclusions.

More analysis of the pressures on the individual in industry is required; in particular, incentive payment systems, methods and standards of inspection, the structure and organization of management, and delegation of responsibility.

The study of individual responses to pressures is as important as the study of the pressures themselves.

The new enthusiasm for industrial sociology has tended to obscure the older studies of individual differences. It may now be time to look at these again in the light of better understanding of the social pressures involved.

Examination of status systems in industry is not new. Nevertheless, there is need to know more about the extent to which the use of the special knowledge and ability of the technician or technologist is hindered by the status systems in industry, particularly the caste system dividing management from technical grades. This is in need of overhaul based on sociological understanding.

The work of Simon and his associates in the United States has shown what can come from a rigorous analysis of some aspects of decision taking. There is a point in each organization at which there is someone who has the necessary authority to take a particular decision. Also located in this organization is someone who has the knowledge for the best decision to be taken. The problem is how to get these two points to coincide: How can effective authority coincide with effective knowledge?

Industrial relations generally means relationship of management to labour. Equally important for the health of any concern is its management/management relations. These may not burst into active conflict, but latent conflict is continuous and may be dangerous. This conflict is neither altogether avoidable nor altogether bad; every time a functional organization is set up a conflict of interest is created. Each functional department tends to seek to maximize what, from the point of view of the organization as a whole, needs to be optimized. For example, a production department will naturally have maximum production as its goal; an inspection department will naturally tend to seek maximum quality or minimum errors. From the point of view of the concern as a whole, a compromise between these conflicting aims has to be achieved. Less obvious but equally profound conflicts of aim will occur between the personnel department and the department of the accountant or financial controller. The problem is not how to resolve this conflict but how best to use it and keep it within bounds.

T. H. HAWKINS

TRAINING ENGINEERING GRADUATES

THE graduate aiming at membership of one of the professional engineering institutions normally undergoes a period of practical training or apprenticeship following the completion of his undergraduate course.

Some three years ago the Institution of Electrical Engineers issued a report entitled "The Training of Graduates" in which the purposes of practical training for graduates were outlined and recommendations for the structure of training courses were made. This report, revised and modified, has now been re-issued*.

The general pattern of training recommended does not differ in its essential features from that described in the earlier report. Training should occupy two years and should comprise basic workshop training, general mechanical and electrical training and what is termed directed objective training. It is emphasized that each phase of the training course should be carefully planned and supervised and that the graduate in his practical training should continue to experience something of the intellectual stimulus and of the urge to intensive individual effort which are inherent in academic studies.

Separate sections of the report deal with schemes of training conducted in a works making heavy electrical plant, a factory for light-current equipment and in an operating organization, such as an electricity supply undertaking or a telecommunication service.

While the majority of electrical engineers study, as undergraduates, electrical engineering, a substantial proportion read physics and a few mathematics. The special needs and interests of such graduates in physics and mathematics are met by a scheme of training based on the laboratory but providing for some direct contact with manufacture and development.

There is one important new feature in the recommendations. This is the recognition of training through experience in a staff appointment as an alternative to the traditional form of graduate apprenticeship. This envisages the graduate being engaged as a member of the staff of a professional engineer who will directly supervise his training. The training course will not then conform to any standard pattern, but will comprise the acquiring of experience on a series of projects. These will be so chosen as to provide in the aggregate a range of experience equivalent to that provided by the normal graduate apprenticeship. Great stress is laid on the personal responsibility accepted by the engineer who undertakes to provide this type of training.

POLIOMYELITIS

SINCE the last World Health Organization specialist Committee on Poliomyelitis met in 1957 not only have inactivated poliovirus vaccines come into widespread use but also live attenuated vaccines have been submitted to intensive study and, in some countries, have already been employed on a scale that could scarcely have been envisaged three years ago. These developments and the problems they raise are fully reviewed in the third report of the Committee (Expert Committee on Poliomyelitis, Third Report. World Health Organization: Technical Report Series, 1960, No. 203; 53 pages. Price: 3*s.* 6*d.*, 0.60 dollars, Sw. Fr. 2. Also available in Spanish and French).

In most countries where inactivated vaccines have been widely used the protection obtained has been of the order expected on the basis of controlled field trials. Manufacturing and testing problems appear to have diminished with increasing experience, but recent attempts to manufacture polyvalent vaccines containing poliomyelitis antigen have raised some special problems. Experience with such multiple antigens is still too limited for their value to be assessed.

The safety of live poliomyelitis vaccines appears to have been satisfactorily demonstrated in a number of areas where they have been used on a large scale, and, in all except two of these areas, the incidence of poliomyelitis has fallen. It is still too soon, however, to evaluate the long-term effectiveness of live vaccines. Criteria for evaluating the safety and effectiveness of such vaccines are formulated in the report. In this connexion, further research on virus markers and on the degree of viræmia produced by different strains is urgently needed. The capacity of the various strains to spread contacts in the community is also a matter needing investigation. The Committee proposed criteria for the selection of suitable strains and for grading various strains of the three sets of vaccines in use. It also gave attention to the possible contamination of live poliovirus vaccines by simian viruses, and recommended the study of their pathogenicity and methods of differential inactivation.

The choice of inactivated or live virus vaccine for large-scale immunization programmes will depend on the epidemiological, social and economic circumstances of the country concerned. The Committee examined the advantages and disadvantages of the two types of vaccine from these aspects and suggested a number of considerations to be kept in mind by public health authorities when deciding which policy to adopt. Emphasis is laid on the importance of serological surveys and surveillance for the efficient conduct of immunization programmes. Finally, attention is directed to the increasing prèvalence of other enterovirus infections (Coxsackie and ECHO viruses) which cause a wide range of clinical manifestations sometimes resembling poliomyelitis. Continued research is needed in this field, especially to detect any increase in the severity of the clinical manifestations in special groups, for example, new-born infants.

UPPER WINDS OVER THE WORLD

THE appearance of *Geophysical Memoir* No. 103 from the Meteorological Office will be welcomed by all who use upper-wind data, whether for geophysical or aviation purposes*. This supersedes *Geophysical Memoir* No. 85, which had the same title, and was published ten years ago, but has long been out of print. The present publication is based, almost entirely, on data for the five-year period 1949–53. Though the International Geophysical Year will have provided a wider coverage to greater heights, it will always be useful to have a detailed analysis of the epoch 1949–53 for reference and comparison, particularly as the information is given for the months of January, April, July and October, rather than as averages for the three-monthly periods of four seasons. This latter procedure was adopted in *Geophysical Memoir* No. 85 on account of paucity of data, but results in excessive smoothing. Average contours are given at the pressure-levels 700, 500, 300, 200, 150 and 100 mb. (approximately 3,000–16,000 m.) and also the average winds are given by diagrams of streamlines and isotachs. The North Polar regions have circumpolar charts for the regions north of 65° N., but no data for the southern hemisphere are given south of 65° S. This is because of the absence of data, for there are large areas of the southern oceans without observations and there must have been a great deal of guess-work there.

Meteorologists will be especially interested in the vertical cross-sections of average zonal wind and potential temperature given for the longitudes 140° E., 75° E., 10° W., 75° W., 130° W. and 180° W. for the same months. These illustrate very dramatically the complexities of atmospheric motions.

In order to estimate the probable wind at any point, it is also necessary to know the standard vector deviation, as well as the average wind. Charts of standard deviation are not provided, but it is promised that they will be given in a later publication.

DIRECTION OF THE GEOMAGNETIC FIELD DURING THE TRIASSIC PERIOD IN SIBERIA

By DR. E. R. DEUTSCH
Imperial Oil Research Laboratory, Calgary, Alberta
AND
N. D. WATKINS
Shell Oil Co. of Canada, Edmonton, Alberta

AN earlier detailed study of the Deccan Trap formation[1,2] revealed, wherever samples were taken, the existence of a stable remanent magnetization making large angles with the ambient field. One explanation has been that India was in middle latitudes of the southern hemisphere during the late Cretaceous or early Eocene. This would also conform broadly to palæogeographical reconstructions offered in the literature, according to which India once formed part of a southern super continent the constituents of which later dispersed.

Such an interpretation prompts the question to what extent the rest of what is now Asia participated in the hypothetical northward drift of India. It

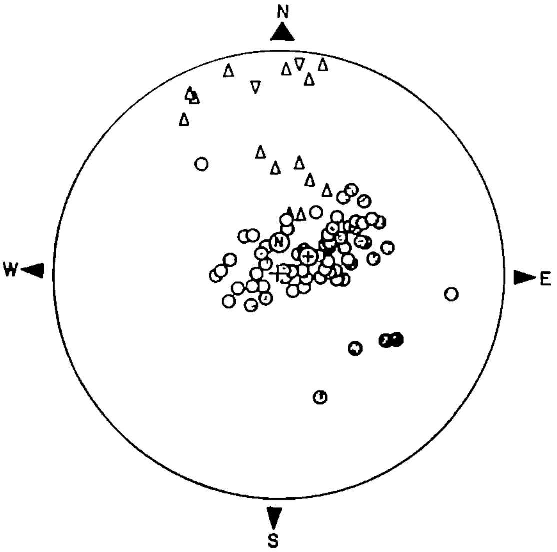

Fig. 1. Polar equal-area plot of the remanent magnetization. Δ, data for specimens from site *C*, N. pole pointing down; ∇, site *C*, N. pole up; ○ all other sites, N. pole down; ⊕, mean direction for all samples, omitting site *C*; *N* in circle, theoretical dipole field at the sampling locality

Table 1. MEAN REMANENT MAGNETIZATION OF SAMPLES FROM SITES *A*, *B*, *D* AND *E*

S	*N*	Declination	Dip	α_{50}	α_{95}	Intensity (c.g.s.)
67	26	N. 62° E.	+76° down	4·0°	8·5°	$(1{\cdot}87 \pm 1{\cdot}14) \times 10^{-3}$

S, number of specimens measured; *N*, number of samples; α_{50}, α_{95}, radii of 50 and 95 per cent circles of confidence, using Fisher's method. All averages are based on samples (*N*), not specimens.

seemed that a promising source of evidence might reside in the palæomagnetism of rock formations north of the Himalayas; in particular, the vast Siberian land mass offers manifold opportunities.

Consequently, in 1957, a request for some oriented samples from Siberia was made to Prof. V. V. Fedinsky of Moscow, then attending the eleventh Assembly of the International Union of Geodesy and Geophysics in Toronto. This was arranged without delay, and in 1958 the University of Alberta in Edmonton received a collection of trap rock from the northern part of the Enisei River system.

The samples are from five exposures in the valleys or basins of the Lower Tunguska, Severnaya and Dudinka Rivers, located as follows (Fig. 2): Site *A*, 66·0° N., 89·0° E.; Site *B*, 69·3° N., 88·0° E.; Site *C*, 66·5° N., 90·1° E.; Site *D*, 66·1° N., 89·0° E.; Site *E*, 66·5° N., 89·1° E. The formations are of Lower Triassic age, range in type from gabbro-diabase to diabase, and at all sites are steeply inclined to the horizontal. Gabbro and gabbro-diabase are elsewhere[3] described as typical of the thick intrusive bodies which characterize the Siberian Traps in this region.

Samples were cut into 1–3 cylindrical disks, which will be referred to as 'specimens'. Direction and intensity of their magnetization were determined with a simple astatic magnetometer, mounted inside a hut belonging to the University of Alberta in Calgary, where we carried out the measurements during summer, 1960.

The stereogram (Fig. 1) shows results for all 83 specimens cut from 32 samples. With few exceptions, the vector extremities of the disks from sites *A*, *B*, *D* and *E* form part of a fairly dense central cluster. In contrast, the plot of points from site *C* is anomalous, and as their scatter exceeds that for any other site, the results were considered unreliable, and hence rejected. The resultant of 26 normalized vectors, all being specimen averages, then corresponds to a west-south-west—east-north-east axis dipping downward steeply towards the east (Fig. 1, Table 1).

In assessing whether this is a true record of the local field direction during Triassic times we make the usual assumption, which seems well supported by theory and some observation, that over periods of 500-1000 years the geomagnetic axis is that of a dipole coaxial with the spin axis. The magnetization of some specimens from each site had been provisionally determined in 1958, but was essentially the same after two years random storage. However, long-term stability may be inferred more compellingly from the data themselves, whenever the vectors form a compact group the mean direction of which is in misalignment with the present local, or dipole, field. The observed angle of deviation, though not large, was taken as significant, for it exceeds the semi-angle of the 95 per cent cone of confidence surrounding the mean vector. Because samples were used in the Fisher analysis, this cone is larger, but probably more indicative of the true scatter at the sampling locality than if all specimens had been weighted equally.

The direction of magnetization furnishes a Triassic north pole in eastern Siberia (Fig. 2, No. 1), as follows:

$$\text{Lat.} = 65^\circ\text{ N.}; \quad \text{Long.} = 156^\circ\text{ E.}; \quad \delta m = 15\tfrac{1}{2}^\circ; \quad \delta p = 14\tfrac{1}{2}^\circ,$$

with δm, δp, semi-axes of the 95 per cent confidence ellipse. Since our investigation began, results of work in the same general area have been published[3] (pole 2);

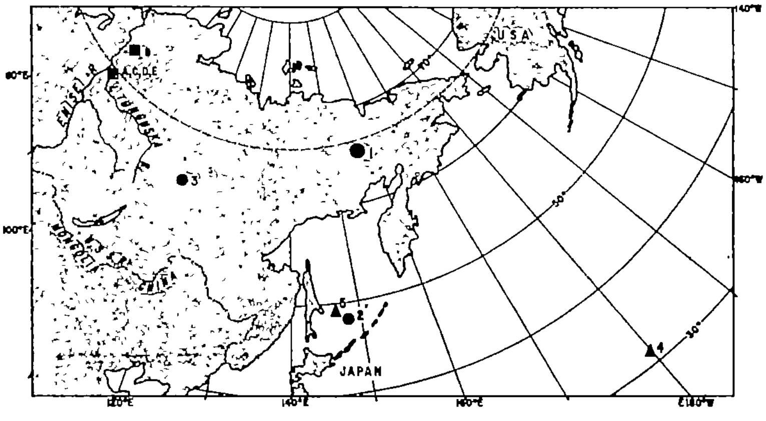

Fig. 2. Location of the north pole with respect to Siberia and Europe, from palæomagnetic measurements on Triassic rocks. Numbers refer to results quoted in this article (1), and by Makarova (ref. 3) (2), Fineberg and Dashkevich (ref. 4) (3), Khramov (ref. 5) (4), and Nairn (ref. 6) (5). Sampling sites are represented by letters

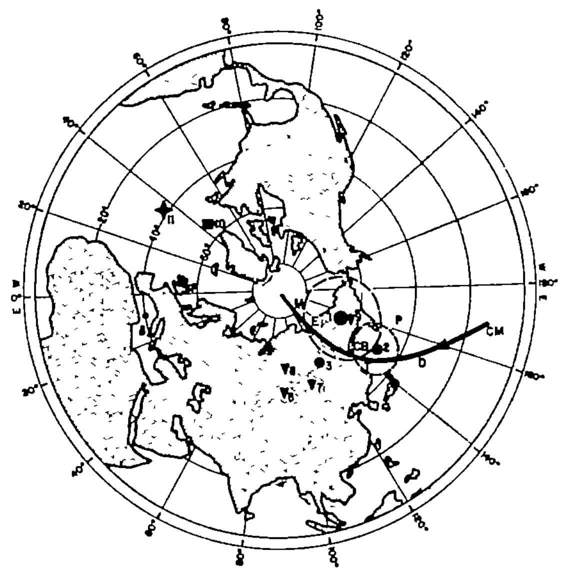

Fig. 3. Location of the North Pole, estimated from palæomagnetic measurements on Triassic rocks. Symbols represent polar plots with respect to: ●, Siberia; ▼, N. America; ■, Africa; ✦, Australia. Numbers indicate source material: 1, our results; 2, 3, other work on Siberian traps (refs. 3, 4); 6, Connecticut lavas (ref. 7); 7, Springdale Sandstone (ref. 8); 8, Brunswickian sediments (ref. 7); 9, New Oxford sediments (ref. 9); 10, Bechuanaland Cave sandstone (ref. 10); 11, Brisbane tuff (ref. 11). The solid line is a polar path relative to Europe, typical of versions published by various authors. *CM*, Cambrian; *D*, Devonian; *CB*, Carboniferous; *P*, Permian; *T*, Triassic; *E*, Eocene; *M*, Miocene

a report[4] on the magnetization of trap rock from the Angara River basin is the source for pole 3.

Palæomagnetic information unlocked from Triassic sedimentary exposures in Europe has yielded pole 4 relative to Russia[5], and pole 5, which is an average quoted by Nairn[6], of British, German and French data by different authors. Our pole, though located rather far north, conforms within limits of error to some point on the smoothed 'European' pole track (Fig. 3). This is not surprising, for it seems likely that in executing any movements inferred from this curve, Europe and northern Asia would have acted as one unit; hence, barring major changes in the Earth's radius, any two contemporary poles from Europe and Siberia should coincide.

Our result differs from three of four pole positions relating to North America[7-9] and, more drastically, from the African[10] and Australian[11] poles. Comparison of global non-Triassic data has revealed many similar discrepancies: the separation of the European and Indian curves exceeds 90° in the Jurassic, the earliest period for which Indian data exist[12]. One can interpret this by invoking large relative displacements between the two land masses, and probably by implication, between India and northern Asia. However, a direct comparison with the Siberian results must await examination of suitable Triassic exposures in India.

We are indebted to Prof. V. V. Fedinsky of the Physics of the Earth Institute, Moscow, and Dr. N. I. Marochkin, director of the Union Geological Research Institute, Leningrad, for making available the rock collection on which this work depended. At the University of Alberta, particular thanks are due to Dr. G. D. Garland, professor of geophysics, for providing workshop facilities and instrumentation, and for his continued interest.

GEOLOGICAL RECONNAISSANCE IN VICTORIA LAND, ANTARCTICA

By B. C. McKELVEY* and P. N. WEBB†
Victoria University of Wellington, New Zealand

IN the summers of 1957–58, 1958–59 and 1959–60, three small expeditions from the Victoria University of Wellington investigated approximately 2,500 sq. m. of ice-free terrain west of McMurdo Sound in southern Victoria Land, Antarctica. The first two expeditions spent a total of 80 days in the field, carrying out topographic surveying, meteorological[1] and gravity studies[2], palæomagnetic sampling[3], zoological and botanical studies, and geological surveys. This article summarizes the results of geological surveys made during the first two expeditions and cites references to papers awaiting publication.

Physiography

The inland ice plateau of eastern Antarctica is bounded at approximately longitude 160° E. by a coastal mountain chain extending 1,000 miles from latitude 70° S. to 85° S. North of latitude 80° S., this mountain chain lies within Victoria Land. Nearly all Victoria Land is completely glacierized; major outlet glaciers flow from the inland ice plateau through the coastal mountain chain to the Ross Sea.

The deglacierized terrain investigated comprises about 2,500 sq. miles of lowland valleys and mountain-

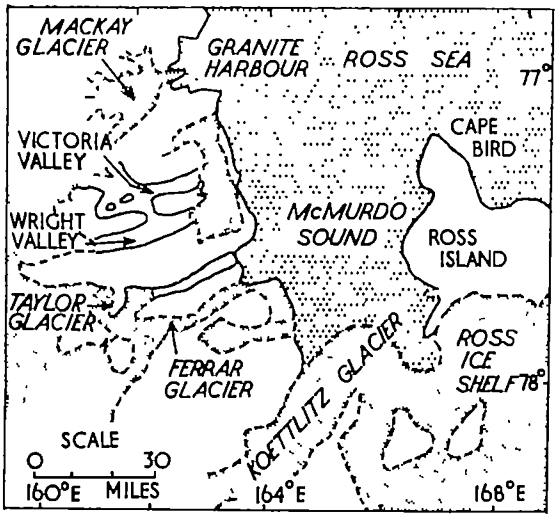

Fig. 1. Locality map of McMurdo Sound region

ous divides lying between the Mackay Glacier (77° S.) and the Taylor and Ferrar Glaciers (77° 45′ S.) (Fig. 1). The Wright Valley and the Victoria Valley system were formerly occupied by glaciers flowing eastwards from the inland ice plateau to McMurdo Sound.

General Geology

In this area, a peneplained Precambrian or lower Palæozoic crystalline basement complex is unconformably overlain by more than 4,000 ft. of Beacon Group sediments (Table 1). Sills and dykes of tholeiitic dolerite intrude both basement complex and Beacon sediments[4].

The Basement Complex. The basement complex exposed in the Wright Valley and Victoria Valley system comprises more than 15,000 ft. of highly folded Precambrian marbles, hornfelses and schists, intruded by acid orthogneiss and coarse porphyritic biotite-hornblende granite. The acid orthogneiss occurs in belts separating the meta-sediments from the biotite-hornblende granite. The meta-sediments strike approximately north to north-west. The foliation of the orthogneiss and porphyritic biotite-hornblende granite also trends north to north-west, parallel to the strike of the meta-sediments. Numerous intrusions of pegmatite and granodiorite dykes with no regular orientation cut through the orthogneiss and the porphyritic biotite-hornblende granite. In the eastern Wright Valley, a swarm of microdiorite dykes dipping south-west intrudes orthogneiss near its contact with the meta-sediments.

Table 1. GENERALIZED GEOLOGICAL HISTORY FOR WRIGHT VALLEY–VICTORIA VALLEY SYSTEM, VICTORIA LAND

Age	Description
Quaternary	At least four phases of glacial cutting and deposition of moraine.
Quaternary to ? Upper Tertiary	Eruption of kenyte, basalt, phonolite and trachyte lavas around McMurdo Sound. Small basaltic cones formed in Taylor Dry Valley, but not in Wright and Victoria Valleys.
? Mesozoic	Intrusion of Ferrar dolerite sills and dykes into the basement complex and overlying Beacon Group sediments.
Mid-Mesozoic to Mid-Palæozoic	Deposition of Beacon Group sediments, including sub-greywacke, arkose orthoquartzite, siltstone and carbonaceous shale facies.
	Major unconformity, with peneplanation.
Lower Palæozoic to Precambrian	Tightly folded, (?) Precambrian marbles, hornfelses and schists intruded by acid orthogneiss and younger granite, granodiorite and diorite. Profuse intrusions of younger acid and basic dyke swarms.

An extensive body of homogeneous biotite-hornblende granite ('pink granite' of early workers) intrudes and in many localities overlies the meta-sediments, gneisses and porphyritic granites. Exposures of hornblende-plagioclase amphibolite up to 500 ft. across occur within this younger granite.

Dense swarms of north-east striking lamprophyre and porphyry dykes intrude all basement rocks and in this region are the youngest intrusives of the basement complex.

Beacon Group Sediments. More than 4,000 ft. of Beacon Group (Mid-Palæozoic to Mid-Mesozoic in age) sediments are exposed in the western part of the Taylor and Wright Valleys and the Victoria Valley system, resting unconformably on the peneplained basement surface[5].

These sediments were examined in detail throughout an area of 800 sq. miles, and are subdivided into five lithofacies. From the base of the group the upward succession is :

(1) Sub-greywacke facies : up to 300 ft. of dark, well-indurated conglomerates, sandstones and siltstones. Bedding structures include thin graded beds, cross-beds, and small-scale slump structures.

(2) Arkose facies : at least 500 ft. thick and overlying the sub-greywacke facies, or more commonly resting on the peneplained surface of the basement complex. Bedding structures include small-scale cross-bedding and thick sequences of black, green, red and white beds repeated rhythmically. Ferruginous concretions are abundant in this facies.

(3) Orthoquartzite facies : at least 2,500 ft. thick and characterized by both massive and large-scale cross-bedded units, with thin interbedded lenses of arkose, subarkose and siltstone.

(4) Red-green siltstone facies : varying between 70 and 300 ft. in thickness and observed only on the southern side of Taylor Glacier, where it overlies the orthoquartzite facies. The sediments comprise thin alternating red and green siltstone units interbedded with beds of arkose and orthoquartzite. Mud-crack horizons and concentrations of worm borings are common in this facies.

(5) Carbonaceous shale facies : at least 500 ft. thick and comprising thin, impure coal seams alternating with cross-bedded and slumped sandstones and siltstones. This facies is well exposed near Pyramid Mountain on the southern side of Taylor Glacier, these rocks being the youngest Beacon Group sediments examined during this investigation.

Ferrar Dolerites. The Ferrar Dolerite sills examined have a total thickness of at least 3,000 ft., distributed through a vertical range of 7,000 ft. (ref. 6).

The lowest sill observed is an undulating sheet up to 800 ft. thick, usually intruded into the granites of the basement complex. However, where this sill encounters steeply dipping meta-sediments, it rises along the bedding planes to the peneplained basement surface and intrudes diagonally up into Beacon Group sediments, thinning markedly as it does so.

A younger sill, approximately 700 ft. thick, has penetrated the unconformity between the basement rocks and the overlying Beacon sediments, and in some places intrudes up to 500 ft. above the peneplain surface. Rarely it intrudes granites below the peneplain surface.

Few of the sills intruding Beacon sediments exceed 400 ft. in thickness. Their pattern of emplacement is extremely irregular and they frequently divide into thinner units. Large feeder dykes have been observed to rise to these sills.

The lowest two sills are mineralogically similar and display marked variation. In their lower levels they are composed essentially of hypersthene, augite and calcic plagioclase, whereas their upper levels consist of augite, pigeonite, less calcic plagioclase, and considerable amounts of micrographically intergrown quartz and alkali feldspar. Autoliths of pyroxene aggregations, up to 2 ft. in diameter, and feldspathic veins occur in the lower levels. The upper levels are characterized by pegmatitic veins and schlieren, and show considerable deuteric alteration.

The sills which intrude Beacon Group sediments are relatively homogeneous, consisting of augite, calcic plagioclase and abundant cryptocrystalline mesostasis.

Quaternary Glaciation. Evidence of four glaciations is recognized in the Wright Valley and Victoria Valleys system[7]. The first two were the most intense. Both carried ice from the inland plateau to McMurdo Sound and the Ross Sea. Highly weathered moraines of the first glaciation lie on glacial benches at heights of 4,500 ft. above sea-level. The second glaciation is represented by a thin veneer of highly weathered moraine on the floors of the present valleys and bench remnants up to 2,000 ft. above sea-level.

Thick moraines of a third glaciation partly overlie the second glaciation moraines, indicating a less-extensive advance into the valleys by plateau, alpine and coastal piedmont glaciers. Associated with the moraines of the third glaciation are salt lakes, evaporite deposits, high-level lake shorelines, dune sands and extensive areas of desert pavement strewn with ventifacts.

The limited distribution of thick coarse moraines in the western part of this area indicates that during a fourth glaciation the remnants of the valley glaciers fed from the plateau advanced only short distances eastwards towards the ice-free central portion of the valleys.

Each glaciation resulted from a build-up in the surface elevation of the plateau, allowing ice to spill over high rock thresholds at the valley heads. With each succeeding glaciation, net increases in elevation of the plateau diminished, until during the third and fourth glaciations it was sufficient to allow only a small volume of ice to flow into the valleys.

Since the fourth glaciation, the volume of ice flowing over the valley-head threshold has been negligible. Plateau, alpine and piedmont glaciers are in the final stages of recession from this area.

SPECTRAL CHARACTERISTICS OF AGGREGATED CHLOROPHYLL AND ITS POSSIBLE ROLE IN PHOTOSYNTHESIS

By SEYMOUR STEVEN BRODY

International Business Machine Research Laboratory, San Jose, California

AND

MARCIA BRODY

Chemistry Department, Brandeis University, Waltham, Massachusetts

IN 1951 Duysens[1] and French and Young[2] reported the fluorescence (720 mμ) of an unknown pigment in the red alga *Porphyridium cruentum*. The fluorescence was attributed to chlorophyll *d* (ref. 1), which had been discovered by Strain[3] in other algae of this group. Because it absorbed at longer wave-lengths than chlorophyll *a*, and because of the highly efficient transfer of energy to it, Duysens assigned to this pigment the role of an energy trap to explain the low yield of chlorophyll-sensitized photosynthesis—especially on the long wave-length side of the red chlorophyll band. However, it was later determined that there is no chlorophyll *d* present in *Porphyridium*[4].

Recently[5], an emission band at 720 mμ was reported for chlorophyll *a*, both *in vitro* and *in vivo*, and was attributed to an aggregated form of chlorophyll. The present investigation shows that the aggregate is a dimer.

The absorption spectrum of the dimeric form of chlorophyll in ethanol was determined (at 293° K.) from the difference in absorption between dilute (10^{-5} *M*) and concentrated ($>10^{-2}$ *M*) solutions of chlorophyll.

Production of the aggregate is accompanied by a symmetrical splitting of monomer bands which is characteristic[6] of dimer formation. The first excited state of the monomer, 665 mμ, gives rise to absorption maxima at 682 and 648 mμ, with absorption coefficients ε_2 and ε_1, respectively (Fig. 1). One would also expect splitting of the second excited state; however, only one absorption band, at 450 mμ, was resolved. The minor absorption bands also appear to split. From its spectroscopic properties, it was deduced that the dimer has the geometry shown in Fig. 2. By using the relationship $\frac{\varepsilon_1}{\varepsilon_2} = \tan\left(\frac{\pi - \theta}{2}\right)$, the angle θ was found to be 130°.

The source of the asymmetry of the long wave-length band (683 mμ) in Fig. 1 may be a metastable

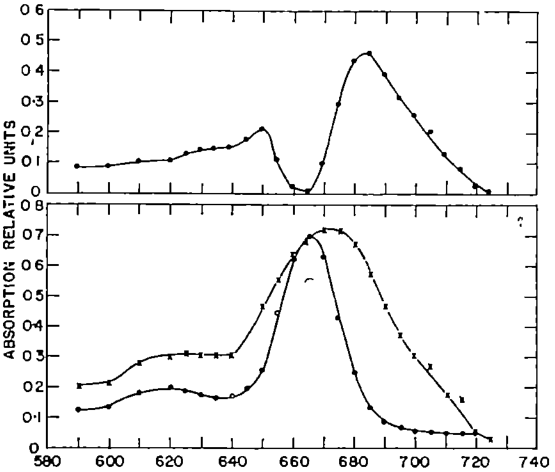

Fig. 1. The curves in the lower graph show the absorption of 10^{-5} M (—o—o—) and 3×10^{-3} M (—×—×—) solutions of chlorophyll *a* in ethanol. The difference in absorption between these two curves is plotted in the upper graph. This difference spectrum, with maxima at 682 and 648 mμ, is considered to be the absorption spectrum of the dimeric form of chlorophyll at long wave-lengths

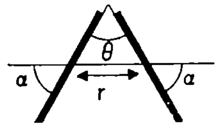

Fig. 2. Geometry of the dimeric form of chlorophyll *a*. Heavy lines depict the planes of the molecules; the angle $\theta \simeq 130°$, and r (the distance between the centres of charge density) $\simeq$ 12 Å.

transition, with absorption maximum at about 705 mμ. Emission from the dimer, at 720 mμ, may originate from this state.

The equilibrium constant for the reaction $2\ \text{Chl}_M \rightleftharpoons \text{Chl}_D$, in ethanol, was found to be approximately 30 mole^{-1}, where Chl_M and Chl_D are monomeric and dimeric chlorophyll molecules, respectively. Observations of the concentration of the monomeric form in the temperature-range 293°–77° K. show that the equilibrium between these two forms is almost independent of temperature. On the basis of the precision of the measurements, the heat of the reaction, ΔH, is estimated to be less than 20 cal./mole. It was assumed that there are two pathways not dependent on temperature and one pathway dependent on temperature by which the excitation energy of the dimer may be dissipated. The pathways independent of temperature are emission and internal conversion; the pathway dependent on temperature is collisional deactivation (*in vivo*, energy-storing chemical reactions will predominate over collisional losses). The rate constant, k_3, for the deactivation pathway dependent on temperature was equated to $A = \exp(-\Delta E/RT)$. In this expression, ΔE is the activation energy and A is the Arrhenius constant. Values of ΔE and A were determined in the following manner. An expression was derived for yield of emission φ from the dimer as a function of temperature:

$$\ln\left(\frac{1}{\varphi} - \frac{1}{\varphi 77°\ \text{K.}}\right) + \ln\frac{k_1}{A} = \frac{-\Delta E}{RT}$$

where φ77° K. is the yield of emission at 77° K. (found to be 0·8 *in vitro* and 0·1 *in vivo*) and k_1, the reciprocal of the emission life-time, is the rate-constant for the emission process ($k_1 = 1/10^{-4}$ sec.). A plot of the above equation gave: $\Delta E = 1{\cdot}0$ k.cal./mole *in vivo* and 0·9 k.cal./mole *in vitro*, and $A \approx 10^5$ sec.$^{-1}$.

This value of A for the dimer is considerably lower than is usually found for uni- or bi-molecular reactions, and may be considered a measure of the *low* transition probability from the excited triplet state to the singlet ground-state.

A relationship was derived between the ratio of dimer to monomer emission (at 77° K.) and the total concentration of chlorophyll. This expression was in good agreement with the experimental results. Included in the derivation is the assumption that a dimeric form of chlorophyll gives rise to emission at 720 mμ. This mathematical relationship was plotted in graphical form, from which it was possible to estimate the concentration of monomer and dimer in *Porphyridium*, *Chlorella*, *Polyedriella* and *Muriella* to be: 3·2 and 2·0, 1·9 and 0·8, 1·6 and 0·6, and 1·0 and 0·2 × 10^{-3} M, respectively. These organisms are arranged in order of decreasing dimer/monomer concentration; it is significant that the wave-number at which the photosynthetic decline occurs decreases along the series.

Since a number of emission measurements were made at low temperatures, it was thought necessary to determine the effect of freezing the cells to 77° K. and then thawing them.

An electron microscope study of material treated in this manner showed a small amount of shrinkage and formation of vacuoles, but no real evidence of disruption of chloroplasts.

Chlorella cells were frozen to 77° K., thawed, and then examined for the Hill reaction. Their ability to carry out this photochemical step (even if with diminished yield) and the fact that changes in absorption were not noted after freezing and thawing, were taken as indicating that these processes introduce no gross changes in the photosynthetic apparatus, or in concentration or aggregation of pigment. It might be added that snap freezing is a method of preservation of activity of the Hill reaction[7].

The action spectrum for exciting emission from the dimer was measured *in vitro* at 77° K., and *in vivo* in several different photosynthetic organisms, at 77° K. and 293° K. The results are in qualitative agreement with the absorption spectrum of dimer in solution.

Action spectra measurements with *Porphyridium cruentum* were made at 77° K. to determine the contribution of the various pigments to emission by chlorophyll. These indicate that light energy absorbed by phycoerythrin is transferred to both monomer and dimer; however, more is transferred to the monomer. Energy absorbed by phycocyanin or the chlorophyll monomer favours transfer to the dimer.

The difference between the action spectrum for excitation of fluorescence at 685 mμ and that at 720 mμ supports the contention that there is more than one form of chlorophyll *in vivo*. A review of the evidence, both ours and other workers[8-10], favouring the existence of two (or more) forms of chlorophyll *in vivo*, will be given in detailed papers which are in preparation.

The concept of aggregated chlorophyll has been used to interpret concentration quenching in solution[11,12]. Lavorel[11] has suggested that the long wave-length decline in fluorescence and photosynthesis might be explained by the presence of an inactive chlorophyll dimer *in vivo*.

We conceive of the dimer as being required for participation in photosynthesis, and propose as necessary in this process the interaction of two unstable products produced by light, one (UP_M) formed by the monomer, and the other (UP_D) by the dimer, respectively. The first stable product, S, of photosynthesis is formed by the dark reaction between UP_M and UP_D. These steps are summarized by the following reactions:

$$X + \mathrm{Chl}_M{}^* \rightarrow UP_M + \mathrm{Chl}_M$$
$$Y + \mathrm{Chl}_D{}^* \rightarrow UP_D + \mathrm{Chl}_D$$
$$UP_M + UP_D \rightarrow S$$

The unstable products may have life-times of the order of a minute and may be identical with the light-induced radicals reported *in vivo* by Commoner *et al.*[13] and Sogo *et al.*[14].

On the basis of the existence of a monomeric and dimeric form of chlorophyll *in vivo*, and the assumptions made above, we will try to give a relatively simple explanation and indicate relationships for a number of the observations in photosynthesis.

It is postulated that some monomer molecules are associated with dimer molecules; direct absorption by these monomer molecules results in energy being transferred to dimer molecules—so that absorption by the monomer leads to formation of both unstable products. However, when the dimer alone is absorbing light, the yield of emission is low and UP_M is not formed. This is the situation that occurs when photosynthesis or fluorescence is sensitized by light absorbed on the long wave-length side of the chlorophyll maximum. Addition of steady or intermittent light of shorter wave-length to that at longer wave-length will permit the reaction sensitized by the monomer to proceed, resulting in full photosynthetic efficiency. As shown above, the onset of the long wave-length decline is related to the concentration of dimer found in various organisms.

Increase in fluorescence yield with light intensity[15] could result from decomposition of the dimer to monomer.

Changes in absorption induced by light[10] may result from shifts of monomer-dimer concentration, or from changes in position of dimer absorption maxima (determined by the angle θ—which, in turn, appears to be effected by such factors as hydrogen ion concentration).

Details of this work will be published elsewhere. We thank Prof. H. Linschitz, of Brandeis University, for his co-operation and provision of apparatus. Part of this work was done at the Air Force Research Center, Bedford, Mass. This work was supported in part by a grant from the National Science Foundation to Brandeis University (grant *G*–6418).

POLYMER MONOLAYERS

By J. M. HAMMOND, MONICA H. WILLIAMS and W. G. P. ROBERTSON

Department of Supply, Weapons Research Establishment, Salisbury, South Australia

IN a recent communication[1] Ries, Beredjick and Gabor described the surface behaviour of polyvinyl benzoate, which showed several unusual features, and directed attention to the wide variation of polymer surface properties with molecular structure. We have recently studied monolayers of three sets of polymers of different structural types, and the results further accentuate the complexity of behaviour obtainable with monolayers of vinyl-type polymers.

The first set of polymers was a series of samples of polymethyl acrylate the viscosity-averaged molecular weights of which varied from $2{\cdot}6 \times 10^4$ to $4{\cdot}75 \times 10^6$. The second set of polymers were graft copolymers of *iso*butene and methyl acrylate in which the number and length of polymethyl acrylate (PMA) branches were varied on a fixed poly*iso*butene (PIB) backbone ('Vistanex' *LM/MS*, $\overline{M}_v$ $4{\cdot}5 \times 10^4$). The third set comprised a number of samples of chlorosulphonated PIB ('Vistanex' *LM/MH*, $\overline{M}_v$ $7{\cdot}2 \times 10^4$) with varying chlorine and sulphur contents, and their hydrolysis products in which the sulphonyl chloride groups had been substantially, if not wholly, converted to sulphonic acid groups. The graft copolymers were prepared by an established photochemical bromination-debromination technique[2] and the Reed-Horn reaction[3] was used for the chlorosulphonation of PIB. Film balance measurements were made at 25° C. on dilute acid (N/100 hydrochloric acid) and other substrates with benzene used principally as spreading solvent. A few results obtained with acid substrate are given in Table 1 and Fig. 1 which include also, for comparison, the results given by Ries, Beredjick and Gabor[1] for polyvinyl benzoate (PVB), polyvinyl acetate (PVAc) and stearic acid.

PMA was found to behave similarly to PVAc but was rather more compressible. The most interesting feature of the PMA results was the observed significant variation in limiting area (23·0–26·5 Å.^{2}/monomer unit) over the range of molecular weight studied. Previously some workers have claimed limiting area to be independent of molecular weight[4]. Others have

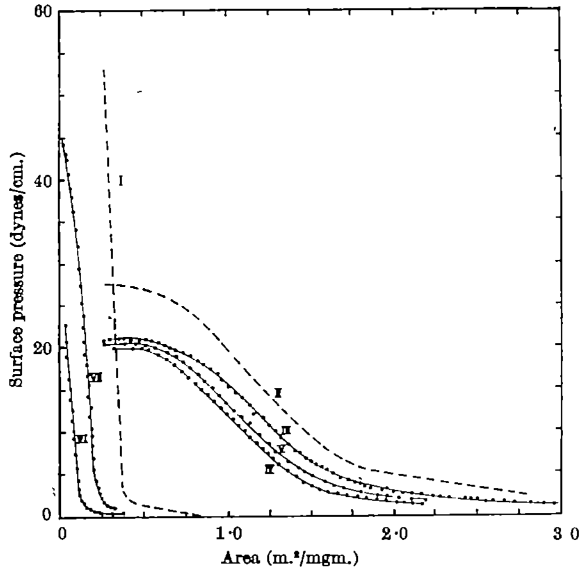

Fig. 1. Pressure-area isotherms. I, isotherm for polyvinyl benzoate (ref. 1); II, isotherm for polyvinyl acetate (ref. 1); III, isotherm for polymethyl acrylate, $\overline{M}_v$ 2·73 × 10^6; IV, isotherm for polymethyl acrylate, $\overline{M}_v$ 3 2 × 10^4; V, isotherm for PMA/PIB graft polymer; VI, isotherm for chlorosulphonated PIB; VII, isotherm for hydrolysed chlorosulphonated PIB

found some increase with molecular weight[5] but not as great as that reported here. However, it does seem that we have gone to rather higher molecular weights than most other workers. It is probable that, with flexible molecules, as the molecule-length increases, intermingling of molecules becomes increasingly restricted so that at the higher molecular weights packing on the surface becomes less efficient.

PMA and PVAc monolayers behave rather similarly, and the behaviour of PVB makes an interesting contrast. In the case of PVB the high collapse-pressure is attended by a low limiting area. The preferred explanation[1], in terms of the postulated formation of rigid coils or folds rising from the surface, would also account for the high resistance to compression in the linear region of the isotherm. A further interesting feature of the PVB isotherm is the very low resistance to compression at areas greater than 0·4 m.^{2}/mgm. In this region monomer units are being forced out of the surface to form the rigid overfilm; the feeble resistance to compression in this region indicates that this ejection from the surface is much more easily achieved with PVB than with PMA and PVAc which do not attain such a high collapse-pressure, but which reach their maximum resistance to compression at areas of approximately 1·5 m.^{2}/mgm.

Table 1. MONOLAYER PROPERTIES

	Limiting area		Collapse pressure (dynes/cm.)	Compressibility (cm./dyne)
	m.^{2}/mgm.	Å.^{2}/monomer unit

† Area per molecule.
‡ Assumed area per PMA monomer unit.
§ Calculated area per PIB unit.

Poly*iso*butene does not spread at all at the air-water interface, neither does brominated PIB at least up to 14·4 per cent bromine content. Mixtures of PMA and PIB were found to behave just the same as if the PIB were not present. This suggests that with the mixture the PIB exists on the surface in a completely collapsed state and its presence in no way affects the behaviour of PMA. It is assumed, therefore, that with the PMA/PIB graft copolymers the behaviour of the PMA branches is not appreciably affected by the presence of the PIB backbone and that the limiting area of the monomer units in the PMA branches is close to that found for homopolymer of similar degree of polymerization, although the two limiting areas may not be identical due to some restriction of the packing of PMA when present as branches. On the basis of this assumption, it was immediately obvious from the results obtained with the graft copolymers that the PMA branches fell short of accounting for the total observed limiting area and that some 11 Å.^{2} must be occupied per *iso*butene unit in the case of the graft copolymer cited in Table 1, which had some two to three branches of PMA ($\overline{P}_v$ 3·21 × 10^2) grafted on to the PIB ($\overline{P}_v$ 8·04 × 10^3). Models of the *iso*butene unit projected on to a plane surface give areas ranging from 14 Å.^{2} to 22 Å.^{2} for various orientations. While the accuracy of calculating in this way the area occupied by an *iso*butene unit in the graft copolymer is debatable, the value obtained (10·7 Å.^{2}) does indicate a surprisingly large extension of the backbone by a few horizontally orientated polymeric branches. Indeed, the result suggests that the actual number of branches present considerably exceeds the number calculated (2–3) from PMA content and average degree of polymerization. The branch degree of polymerization was assumed to be the same as the $\overline{P}_v$ of a PMA homopolymer prepared under similar conditions of rate, solvent (cyclohexane) and transfer agent (triethylamine). This method of calculating branch frequency overlooks, by its very nature, the possible existence of numerous branches much shorter than the average.

Hydrolysed chlorosulphonated PIB polymers (HCS–PIB) gave high collapse-pressures, up to 44 dynes/cm. The unhydrolysed chlorosulphonated polymers (CS–PIB) gave much lower collapse-pressures and were much less resistant to compression than their hydrolysis products. Calculation of limiting areas for these randomly substituted polymers in terms of Å.^{2} per monomer unit are rather approximate. The values thus obtained are very low and indicate, as one would expect from the relatively infrequent occurrence of polar groups, that these polymers are not horizontally orientated. Areas occupied per polar group were in the range 20–30 Å.^{2}, that is, comparable with the limiting area per molecule of stearic acid. It is evident that the hydrocarbon chain forms loops above the surface and this permits fairly close packing of polar groups. In spite of some similarity with stearic acid type behaviour, these polymer films are much more compressible: more compressible in fact than PVB (horizontally orientated, high collapse-pressure) and more akin, in this respect, to PVAc and PMA (horizontally orientated, low collapse pressure).

Less highly substituted chlorosulphonation derivatives of PIB were, as expected, less surface-active than the examples given in Table 1. More highly substituted derivatives were also less active ; this is attributed to partial solubility since with increasing substitution there is an increasing possibility of highly polar groups occurring sufficiently close together to render portions of the molecules soluble in water.

HCS–PIB polymers gave solid films, while the CS–PIB, PMA and graft polymer films were fluid.

A detailed account of this work and further discussion is being prepared for publication.

Acknowledgment is made to the Chief Scientist, Department of Supply, South Australia, for permission to publish this work.

HIGH-YIELD CRYSTALLIZATION OF UREASE FROM JACK BEAN

By Dr. KIYOMICHI HANABUSA

Department of Biochemistry, School of Medicine, Keio University, Tokyo

CRYSTALLIZED urease of jack bean was obtained by Sumner[1] by quite a simple procedure, but very few samples of jack bean are suitable as the starting material for this method. The causes of the difficulties are believed due to : (1) the samples contained a relatively small amount of urease[2] (less than 90 units per gm.) ; (2) in the case of some samples urease is difficult to extract with 32 per cent acetone, as the first step of method, while containing the usual amount of enzyme[3]. Jack beans cultured in Japan belong to this type[4].

To obtain the preparation of urease crystals from these samples is impossible by Sumner's method. The present investigation was undertaken to find a method of purification of urease which is applicable to such samples.

In an attempt to provide crystallized urease by the application of methods usual for other enzymes it was observed that, as the purification proceeds, urease was apt to be converted so as to be insoluble in water, especially after treatment with acetone. This insoluble form of urease with its activity still preserved has already been studied by Sumner[5]. Because of this, any kind of usual fractionation procedure was not applicable for further purification. This insoluble form was changed into a soluble one by mixing with urea ; but after dialysation it was not susceptible to any fractionation, and SH_2 seemed to have little ability to dissolve this insoluble form. Uehara and Kobashi demonstrated that cysteine can convert this insoluble form into the soluble form[6]. I used 2-mercaptoethanol instead of cysteine and devised a method of preparation of crystalline urease with good yield from jack bean, though it contains a low concentration in units of urease.

Jack beans cultured in Japan, *Canavalia ensiformis* var. *gladiata*, were used. They were pulverized into fine powder which contained 100–180 units of urease per gm. The defatting treatment was unnecessary for the present purpose. Acetone was treated with a small amount of potassium permanganate and anhydrous potassium carbonate, then distilled. Calcium phosphate gel was prepared by the method of Tsuboi and Hudson[7].

Both the colorimetric timing method[8] and Iwasaki's azotometry[9] were used for the assay of urease activity under conditions devised by Sumner and Hand[2], and the latter was employed when an accurate value was required. For the determination of protein nitrogen the sample was first digested as usual and the nitrogen of ammonium salt was determined by Iwasaki's azotometry[10]. Protein including urease[11] was calculated by assuming that it contains 16 per cent of nitrogen. The specific activity, that is, units per gm. of protein, was calculated from the foregoing data.

Utilization of several procedures usual in the purification of other enzymes has been studied, of which the following series of procedures was most satisfactory. All work was carried out at room temperature, and distilled water made by a gilded-tin vessel was used throughout the work. 500 gm. of jack bean meal to which 2·5 litres of water had been added and stirred for 10 min. was first filtered through a cloth sack. The residue was again treated with 1·0 litre of water and treated in the same manner, then both filtrates were collected, suspended together with 'Celite' and filtered again through a Büchner funnel. About 3 litres of yellowish brown, slightly turbid, filtrate was obtained.

To 3 litres of filtrate, 1,370 gm. of solid ammonium sulphate was added to give 60 per cent saturation. After a few hours, the resulting precipitate was collected by centrifugation and dissolved in 700 ml. of water. The solution was dialysed against a stream of tap water for about 24 hr., enough time for there to be precipitated the considerable amount of resulting denatured impurities ; these were centrifuged off and discarded. Approximately 1,700 ml. of dialysate was obtained.

The dialysate was mixed with 850-ml. portions of calcium phosphate gel. The *p*H of the mixture was adjusted to 5·0–5·5 with 1 *N* acetic acid and allowed to stand for 20 min. with gentle stirring. The gel was collected by centrifugation. It has been shown from experimental results that for each 100 mgm. of protein in the dialysate 50 mgm. of calcium phosphate gel in dry weight was necessary for almost complete adsorption of urease. Usually 1 ml. of dialysate includes 13–18 mgm. protein, and the same amount of gel includes 14 mgm. of calcium phosphate; accordingly, one might use expediently one volume of gel to two volumes of dialysate for adsorption of the enzyme.

Elution was accomplished by gentle mixing of the gel, avoiding foaming with 200 ml. portion of $M/15$ phosphate buffer, *p*H 7·5, for 15 min. This is done three times, and the eluates obtained after centrifugation in each case were pooled. Total eluate was approximately 600 ml. and displayed the activity of between 6,000 and 8,000 units per gm.

The eluate was made up to 50 per cent saturation with ammonium sulphate by adding 230 gm. of it and kept for 5 hr. At the end of this time, the precipitate was recovered by relatively high-speed centrifugation, dissolved in 80 ml. of water and the enzyme solution was dialysed against 2 litres of distilled water for 15 hr. (or overnight) in the cold. The outer fluid was renewed three times during the dialysis and about 150 ml. of dialysate was obtained, of which activity was about 12,000 units per gm.

Urease in the dialysate was changed into insoluble form by precipitation with acetone. At first the dialysate was brought to $M/15$ referring to potassium phosphate by addition of either solid potassium dihydrogen phosphate or 0·5 M of its solution. If some amount of precipitate had appeared during the period of dialysis it was usually redissolved by this treatment. (This precipitate contains considerable urease so it should not be discarded.) Urease in solute state was then precipitated by dropwise addition of 0·6 vol. of acetone with continuous stirring. To ensure that the urease is converted completely into insoluble form, the mixture was allowed to stand for 2 hr. at room temperature. Then the precipitate containing the insoluble form of urease was collected by centrifugation and washed with a small portion of water. Usually 93–99 per cent of urease activity in dialysate was recovered in the precipitate by this procedure.

The insoluble urease is made soluble by the action of 2-mercaptoethanol and the majority of the impure protein rejected as the insoluble part, so that the specific activity will increase considerably in this step.

A mixed solution composed of 36 ml. of 0·025 M citrate buffer *p*H 7·0 and 4·0 ml. of ten times diluted aqueous solution of 2-mercaptoethanol was added to the acetone precipitate, stirred enough to be homogeneous and allowed to stand for 1·5 hr. with intermittent stirring, after which the remaining precipitate was centrifuged off. In this instance, approximately 70 per cent of the activity was transferred to the supernatant, amounting to 40 ml. After this was adjusted to *p*H 6·0 with 0·1 M citric acid, 0·3 vol. of acetone (12 ml.) was added and kept in an ice chamber at 5° C. Urease was soon crystallized out and the crystallization was completed within a few hours.

The crude crystals generally included a small amount of insoluble impurities. The recrystallization was easily achieved by the method of Dounce[12]. The content of nitrogen, urease units, specific activity and yields at each step in each instance are shown in Table 1, as an example.

Urease was purified some 1,000 fold from starting material with yield 23–33 per cent and crystals were also obtained from material showing a low activity of only 65 units per gm. Attempts to simplify the procedure described here were made, but a satisfactory result was not obtained.

Table 1

	Total N (mgm.)	Total units (×100)	Specific activity (units/gm.)	Yield (per cent)
Starting material	—	680	136	100
Water extract	23,500	630	428	92·5
First ammonium sulphate fractionation	5,290	575	1,740	84·4
Calcium phosphate gel eluate	885	378	6,830	55·5
Second ammonium sulphate fractionation	458	326	11,400	47·9
Precipitate with acetone	378	300	12,700	44·1
Redissolved solution	95·2	236	39,700	34·7
Crude crystal	41·4	221	85,400	32·5
Recrystallization once	29·7	212	114,000	31·2
Recrystallization four times	20·4	166	130,000	24·4

The urease crystals obtained in this way were colourless octahedrals in form of 3–8μ in diameter. A photograph by phase contrast microscope is presented in Fig. 1. The specific activity of pure urease crystals which were recrystallized four times was determined; they had an activity of 130,000 units per gm. The electrophoretic experiments with them were carried out in veronal buffer of ionic strength 0·05, *p*H 8·6 and in $M/30$ phosphate buffer, *p*H 7·0, respectively. Only one single and symmetrical peak was observed under these conditions.

Ureases which occur in some kinds of jack beans are with difficulty extracted with aqueous acetone, though these samples include sufficient amounts of urease in them[3,4]. They are unsuitable as starting material for the method by Sumner. However, almost all the urease in any sample is easily extracted with water; because of this the aqueous extract of urease was made in the first step. It is reasonable to assume that some obstructive factors may exist in these samples when aqueous acetone was used for the extraction of urease. Sumner demonstrated previously that purified urease was converted into insoluble form by the procedures consisting in adding ethanol and sodium chloride to its solution and keeping it at room temperature[5]; moreover, even crystalline urease gave the same result[13]. I found that, as the purification of urease

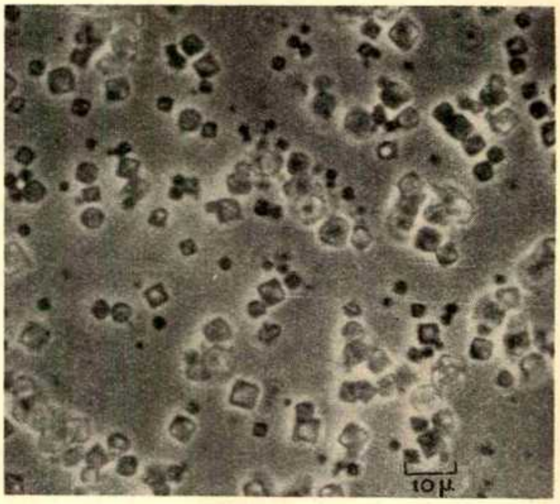

Fig. 1

proceeded, more than 10,000 units per gm. could be easily converted into the insoluble form by addition of acetone. Uehara and Kobashi proved that insoluble urease recovered its solubility by the action of cysteine or glutathione. In the present work, loss of activity was scarcely recognized when urease was converted into insoluble form by treatment with acetone. It recovered its solubility by the action of 2-mercaptoethanol ; at the same time a small portion of impure protein was also redissolved out of the insoluble precipitate. This was found as insoluble impurity when urease was recrystallized. From these points of view it is reasonable to infer that among the sulphydryl groups of the urease molecule there must be a special part which is relevant to the formation of the insoluble form as well as indifferent to the revealing of enzyme activity, and the formation of disulphide linkages does not occur only between urease molecules themselves but also between different protein molecules. Urease was crystallized with good yield starting from aqueous extract of jack bean meal ; whereas it might be unsuitable for Sumner's method. Urease crystals thus obtained were identical with respect to the crystal form and activity to those obtained by Sumner's method[14].

I wish to express thanks to Prof. K. Sekita for his kind guidance and constant encouragement throughout this work. Thanks are also due to Dr. K. Kobashi for his helpful suggestions. This work was supported in part by a research grant from the Taito-Pfeizer Co., Ltd.

INHIBITION OF THE MULTIPLICATION OF INFLUENZA VIRUS BY ANILINE DERIVATIVES OF THE FRANCIS INHIBITOR

By Dr. I. HOLLÓS

State Institute of Hygiene, Budapest

It is generally accepted that the red-cell receptor concerned in hæmagglutination by myxoviruses is an analogue of the receptor substances of cells which are susceptible to infection[1]. Two findings seem to support the active role of the receptor[2] in virus multiplication : (1) its amount is subjected to a cyclic fluctuation during the process of multiplication[3] ; (2) both the early and late stages of multiplication are inhibited by the same chemical compounds[4].

To investigate this question, human serum α-inhibitor (Francis inhibitor[5]) was prepared from Cohn's 4/4 fraction as recommended by Hirst[6]. The inhibitor was completely inactivated at room temperature by any of the active influenza virus preparations tested.

The interaction between influenza virus A^1 Budapest 4/49 (*Bp*) and α-inhibitor is shown in Fig. 1,*A*. Equal volumes of virus and α-inhibitor solution were kept at room temperature. At intervals, 1 ml. samples were mixed with 0·2 ml. of a 5 per cent suspension of fowl erythrocytes, kept in an ice-bath for 15 min. and centrifuged. The erythrocyte sediment was taken up in 0·5 ml. phosphate buffer, incubated at 37° C. for 2 hr., and centrifuged. The supernatants were titrated by Takátsy's micromethod[7] for hæmagglutinin, to determine the amount of virus recovered from the erythrocytes. There was a sudden drop in the recoverable virus in the early minutes, followed, even if virus had completely disappeared, by a rise nearly up to the initial hæmagglutination titre.

The disappearance and reappearance of virus might be explained by a competitive antagonism between α-inhibitor and erythrocyte receptor. At the beginning, α-inhibitor, being in excess, prevents the adsorption of the virus on the erythrocytes, but later, as the virus gradually inactivates the inhibitor, more and more of it will become demonstrable.

According to Wolley's concept[8], a hæmagglutination inhibitor is expected to inhibit virus multiplication only if it combines with the virus more firmly than does the cell receptor. Mandel and Racker[9] found such an inhibitor to the *GDVII* virus in the intestinal tract of the mouse.

In attempting to prepare influenza virus inhibitors meeting this requirement, we coupled aniline derivatives by diazonium linkage to a purified preparation of α-inhibitor. Coupling was followed by a second purification consisting of fractionations with alcohol, and dialysis at 4° C. against a *p*H 7·2 buffer solution for 3 days. The purified preparation was stored in a frozen or lyophilized state. Control preparation (No. 17, Table 1) was submitted to all the procedures of coupling (mainly oxidative procedures) except for adding aniline derivative.

Table 1. RELATIVE INHIBITORY ACTIVITY OF MODIFIED α-INHIBITORS

Preparation No.	Modifying compound	D_{75} in hæmagglutination inhibitor units as tested with 10^4 ID_{50} of			
		PR8	*Bp*	Singapore 1/57 non-avid	Lee

17	None	204	204	> 204	110

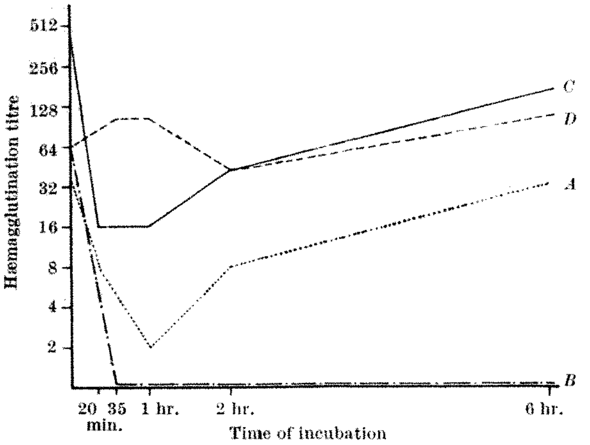

Fig. 1. Influenza virus (strain A^1 Budapest 4/49) recoverable from inhibitor-virus mixtures after incubation for different periods by adsorption to and elution from chicken erythrocytes. Arithmetic means calculated from five experiments

A, 128 *HA* units of virus + 64 *HAI* units of α-inhibitor; *B*, 128 *HA* units of virus + 64 *HAI* units of α-inhibitor, coupled to *p*-phenylenediamine; *C*, 512 *HA* units of virus + 64 *HAI* units of α-inhibitor, coupled to *p*-phenylenediamine; *D*, 128 *HA* units of virus + 3 mgm./ml. *p*-phenylenediamine

HA unit = the amount in 1 ml. of virus suspension causing partial hæmagglutination; *HAI* unit = the amount in 1 ml. which partially inhibited hæmagglutination produced by 1 ml. of Lee virus containing 4 *HA* units

Fig. 1,*B* illustrates an experiment with the *p*-phenylenediamine derivative of α-inhibitor. To prepare this substance, 3 mgm. of the lyophilized α-inhibitor was taken up in 1 ml. buffer solution and coupled to 3 mgm. *p*-phenylenediamine. (The lyophilized material could not be redissolved completely.) When virus was added to this modified inhibitor, a sudden decline in the virus recoverable from erythrocytes occurred. If high-titre viral preparations were used, some rise was observed later (Fig. 1,*C*), but when the virus preparation had an initial titre comparable with those used in the above experiments, no virus could be demonstrated in the eluates during the 6-hr. period of experiment (Fig. 1, *B*). The total disappearance of virus, which has been demonstrated in numerous experiments, could not be attributed to either the α-inhibitor or the uncoupled chemical compound alone (Fig. 1, *A* and *D*).

The inhibition of virus multiplication was examined by Horváth's roller-drum micro-technique[10]. To determine the strength of the inhibitor several dilutions were tested. First, the inhibitor dissolved in 0·5 ml. medium was placed in each vial, then the allantoic membrane fragments in 0·1 ml. were added, and finally 0·1 ml. of the *Bp* strain of virus. The infective titre of the virus alone was also determined as a control. Eight cultures were inoculated with every dilution. After 72-hr. incubation, each culture medium was titrated for hæmagglutination. The inhibition of viral multiplication was expressed as the percentage difference between the arithmetic mean of hæmagglutination titres in the control vials and that for the experimental group. The inhibitory potency of a substance was characterized by the dose which caused a 75 per cent inhibition (D_{75}). In Table 1, D_{75} is expressed in hæmagglutination inhibition units. (One such unit is present in 1 ml. of a preparation which partially inhibits the hæmagglutination of a suspension containing 4 hæmagglutination units Lee virus, in the indicator state, per ml.) In order to estimate the reproducibility of the index D_{75}, that for the diethyl-*p*-phenylenediamine-diazonium-α-inhibitor was determined against 10^4 ID_{50} in five experiments. The coefficient of variation as multiplied by Student's value was found to be ± 55 per cent. In the vials containing too little inhibitor to cause any inhibition the hæmagglutination titres slightly exceeded the control ones. This slight rise in titre was reproducible and found in every experiment. Regardless of this, the relation of inhibitor concentration to the percentage inhibition appeared to be approximately rectilinear and was scarcely influenced by the strength of the inoculum.

According to the D_{75} values determined against three strains (Table 1), preparations Nos. 3, 8 and 1 are considerably more potent (2·75–255-fold) than the control preparation. It was a general observation that different strains were differently inhibited by the same compound. Some preparations, such as No. 14, were even ineffective with one or two strains while definitely effective with others. The inhibition of multiplication by larger doses of the control preparation might be explained by thermo-inactivation occurring while the virus is fixed to the inhibitor.

To obtain some information on the mechanism of inhibition, preparation No. 8 was added to an excess of active virus, kept at room temperature for 48 hr., centrifuged at 20,000 *g* for 1 hr., and the supernatant was heated to 90° C. to inactivate any virus possibly present. The heated supernatant failed to inhibit virus, indicating that the inhibitor had sedimented in combination with virus. (Free inhibitor was not sedimented in control experiments; heating to 90° failed to inactivate inhibitor.)

The inhibitory effect of substance No. 8 has been studied in the embryonated egg. Sixty eggs were infected with 10^5 ID_{50} of the *Bp* strain. Twenty eggs were each given 0·5 ml. of a solution containing 48 hæmagglutination inhibitor units 30 min. before infection, another twenty the same dose 30 min. after infection. The remainder served as control. After 48 hr. incubation the infective titres in the three pools of allantoic fluids were $10^{-7·4}$, $10^{-7·5}$ and $10^{-9·2}$, respectively. A similar inhibition (2·0 $\log_{10}$ units) was demonstrated with the Lee strain as test virus.

Thus it is concluded that some modified preparations of α-inhibitor, being as avid for the influenza virus as α-inhibitor itself, combine with the virus more firmly than α-inhibitor does. Marked reduction in the amount of virus multiplication by preparation No. 8 has been demonstrated in the egg with two strains of virus even if inhibitor was injected 30 min. after infection. The modified inhibitors are expected to help us in studying the role of cell receptor in the multiplication of myxoviruses. Similar derivatives of neuramic acid esters might be of more practical importance.

This work will be published in detail in the *Acta Microbiol. Hung.* (Budapest).

ACTION OF *VICIA FABA* ON ERYTHROCYTES: POSSIBLE RELATIONSHIP TO FAVISM

By Dr. J. E. BOWMAN and Dr. D. G. WALKER*

Department of Pathology, Shiraz Medical Centre, Nemazee Hospital, Shiraz, and Department of Biochemistry,
University of Shiraz, Shiraz, Iran

THE disease favism is a hæmolytic anæmia which results from the ingestion of the broad bean (*Vicia faba*) by some people. The disease has been recognized in most countries around the Mediterranean Sea for many years, and its clinical manifestations have been well documented[1]. Work both in Italy[2] and Israel[3] has shown that the disease only occurs in persons who have an inherited abnormality of the erythrocytes in that there is a deficiency of the enzyme glucose-6-phosphate dehydrogenase. This basic deficiency is reflected in a lowered level of the amount of reduced glutathione in the red blood cells and an instability of the glutathione in the presence of certain substances such as acetylphenylhydrazine, aniline, hydroxylamine, α- and β-naphthol and the anti-malarial drug primaquine[4]. Such agents cause both *in vitro* and *in vivo* breakdown of erythrocytic glutathione, whereas agents such as ascorbic acid and cysteine cause *in vitro* destruction only[5,6].

We recently reported[7] that extracts prepared from fresh beans of *Vicia faba* show a selective effect upon the glutathione of erythrocytes from sensitive subjects, that is, those possessing the genetic abnormality. This work has now been extended to show that the active agent of *Vicia faba* is present also in extracts of pollen and pistils, that the effect on glutathione can be demonstrated simply by incubating whole blood of sensitive subjects with whole beans and that the effect is not due to common reducing agents such as ascorbic acid and cysteine.

Table 1 shows the effect of incubating 1-ml. blood samples from both sensitive and non-sensitive subjects with 0·1 or 0·2 ml. amounts of extracts of pollen and pistils. Blood glutathione-levels were measured before and after incubation[6]. The pollen extracts were prepared by suspending 1 vol. of loose pollen in 10 vol. of saline at 4° C. for 1 hr. followed by centrifugation at 500 r.p.m. for 2 min. Pistil extracts were prepared in a similar manner using 5 vol. of saline. Fresh young beans (approx. 8 mm. in maximum diameter) were used in the whole-bean experiments. In all three cases, the incubations showed a significant *in vitro* effect on blood from sensitive subjects compared with non-sensitive subjects.

Table 1. EFFECT OF EXTRACTS OF POLLEN AND PISTILS AND OF WHOLE BEANS ON ERYTHROCYTIC GLUTATHIONE

Source of activity	Vol. of extract used (ml.)	Subjects	No. of samples	Glutathione (mgm. per 100 ml. red blood cells) before incubation	after incubation	*P* value on basis of '*t*' test
				Mean S.D.	Mean S.D.	
Pollen extract	0·2	Sensitive	10	33·2 ± 5·0	21·3 ± 3·2	0·01
		Non-sensitive	8	55·3 ± 8·3	48·0 ± 6·3	
Pistil extract	0·1	Sensitive	10	36·1 ± 4·8	26·8 ± 4·2	0·001
		Non-sensitive	10	56·5 ± 6·0	52·6 ± 7·0	
Whole bean	—	Sensitive	10	36·2 ± 5·3	28·4 ± 5·0	
		Non-sensitive	10	61·8 ± 8·8	61·9 ± 9·1	

This effect cannot be due to cysteine because this would give a colour with the nitroprusside reaction used for estimating glutathione. Control experiments showed that the addition of extracts to blood followed by immediate precipitation of the proteins and glutathione estimation (with no incubation period) has virtually no effect upon the apparent blood glutathione-level. Hence the extracts do not contain significant amounts of cysteine. Further, the effect of the extracts is not due to the action of ascorbic acid. To demonstrate this, an extract of fresh young beans was prepared using ½ vol. of saline by the method previously described[7]. The action of 0·2 ml. of this extract (which contains not more than 3 μgm. of ascorbic acid in the 0·2 ml., an amount far below the concentrations reported to have an *in vitro* effect on erythrocytic glutathione[5]) was compared with the effect of incubating 1 ml. of blood with 2 mgm. of ascorbic acid in 0·2 ml. of saline. With an incubation time of 10 min. only the *Vicia faba* extract had a marked effect upon erythrocytic glutathione (Table 2).

These experiments show, therefore, that *Vicia faba* pollen and pistils, in addition to the bean, itself contain an active principle which has a marked effect on the erythrocytic glutathione of sensitive subjects. The action is not due to ascorbic acid or cysteine so that a specific effect of *Vicia faba* is still indicated. This direct action on the red blood cells *in vitro* suggests a way in which ingestion of the bean or inhalation of the pollen might result in *in vivo* hæmolysis.

It remains to demonstrate that the effects shown in this article are specific for *Vicia faba* and are not given by other vegetables at least to the same extent. Whole fresh peas, incubated as in the whole-bean experiments, showed no effect. Certain other vegetables tried, for example, runner beans, caused massive agglutination of the erythrocytes. When this occurs, false low glutathione-levels are obtained, probably due to lack of complete hæmolysis which is necessary for accurate estimation of the whole

Table 2. EFFECTS OF *Vicia faba* EXTRACT AND OF ASCORBIC ACID ON GLUTATHIONE OF THREE DIFFERENT SAMPLES OF 'SENSITIVE' ERYTHROCYTES

Before incubation	After incubation with ascorbic acid	After incubation with *Vicia faba* extract
42*	43	29
34	35	24
44	44	28

* All values are in mgm. glutathione per 100 ml. red blood cells. The incubation time was 10 min.; for details see text.

blood glutathione-level. With *Vicia faba* extracts, we have noted non-specific falls in glutathione if added to non-sensitive blood containing insufficient ACD. In these instances coarse clumps of blood were observed. This effect is abolished with the addition of further anticoagulant. Only those results obtained in the absence of agglutination are therefore valid for the purposes of comparison. In our experience, *Vicia faba* extracts are the only ones so far tested which give a statistically verified selective *in vitro* action on erythrocytic glutathione of sensitive subjects.

Though these results in no way prove that favism is caused by a direct action of an agent in *Vicia faba* on erythrocytes by initiating hæmolysis, they strongly suggest that such a possibility should be tested *in vivo*. Such a direct action appears to offer an attractive alternative hypothesis as to how sensitive subjects may develop a hæmolytic anæmia following ingestion of the broad bean, although the evidence for allergy in addition to the genetic erythrocytic defect cannot be excluded[8].

We are grateful to the Misses Annerose Oemisch and Iran Haffarian for technical assistance and the Wellcome Trust (London) for financial support to one of us (D.G.W.).

A GENE DETERMINING PRESENCE OR ABSENCE OF ε-N-METHYL-LYSINE IN *SALMONELLA* FLAGELLAR PROTEIN

By Dr. B. A. D. STOCKER and Dr. M. W. McDONOUGH
Guinness–Lister Research Unit, Lister Institute of Preventive Medicine, London, S.W.1
AND
Dr. R. P. AMBLER
Department of Biochemistry, University of Cambridge

ACCORDING to current views on the gene control of protein structure[1], the amino-acid which is to constitute a particular link in the polypeptide chain of a given protein is specified by a group of bases in a corresponding region of the deoxyribonucleic acid (DNA) molecule of a gene which determines the structure of this protein. Only twenty amino-acids, all in the L configuration if optically active, are common constituents of proteins, and it has been suggested that only twenty different base-groups occur in DNA which specify amino-acids. This hypothesis predicates: (*a*) that the presence of an uncommon amino-acid in a protein always results from some cause other than its specification by a group of bases in the DNA of the gene determining the amino-acid sequence of the protein (for example, from conversion of a common amino-acid into an uncommon one after its incorporation in a polypeptide chain); and (*b*) that heritable variation in respect of the presence or absence of an uncommon amino-acid in a particular protein must result from the action of a genetic determinant other than the gene determining the amino-acid sequence of this protein. An experimental test of predicate (*b*) has now been made in respect of the uncommon amino-acid ε-N-methyl-lysine, which Ambler and Rees[2] reported as a constituent of the flagellar protein ('flagellin') of some bacteria of the genus *Salmonella*; in the material they examined lysine and N-methyl-lysine were about equally abundant. We have now found that N-methyl-lysine is absent from some *Salmonella* flagellins; and by genetic analysis, using phage-mediated transduction[3], we have located a gene determining the presence or absence of N-methyl-lysine in flagellar protein.

Flagellins from many *Salmonella* strains of various species (serotypes) were tested for N-methyl-lysine by paper electrophoresis of acid-hydrolysed flagella with results to be reported in detail. In the case of diphasic strains (that is, strains able to produce flagella of either of two distinct antigenic types) flagella were collected from cultures in phase 1 and from cultures in phase 2. In each of the ten diphasic strains tested, the two flagellins obtained were alike in respect of presence or absence of N-methyl-lysine. Seven strains of *S. typhimurium* (phase 1 antigen *i*; phase 2 antigen 1,2,3) were all positive for N-methyl-lysine; four strains of *S. paratyphi B* (antigens *b* and 1,2) were all negative for N-methyl-lysine. But of thirteen strains of *S. derby* (phase 1 antigen *f,g*; no second phase), four were negative for N-methyl-lysine, the rest being positive.

We next tested flagellins from a series of motile derivatives of *SW* 543, a non-flagellated monophasic strain of *S. paratyphi B* with the (latent) phase 1 flagellar antigen *b*. The flagellar protein of a flagellated mutant of this strain lacked N-methyl-lysine, like the flagellins of other strains of *S. paratyphi B* tested. Strain *SW* 543 lacks flagella because of mutation at a *fla* locus close to the locus which regulates the phase 1 flagellar antigen, and motile clones obtained from it by transduction of the *fla*+ gene from a motile donor strain, are of two sorts: one sort show flagellar antigen *b*, and are attributed to replacement of only the *fla*− gene of strain *SW* 543 by its wild-type allele from the donor strain; the other sort have the phase 1 flagellar antigen of the donor strain, and are attributed to replacement of both the *fla*− gene and the linked gene determining the phase 1 flagellar antigen *b* of strain *SW* 543 by their alleles from the donor strain[4]. Of nine motile transductant clones of the latter type, with phase 1 flagellar antigens derived from various donor strains, eight were positive for N-methyl-lysine; the donor

Table 1. ANTIGENIC CONSTITUTION AND N-METHYL-LYSINE CHARACTER OF THE FLAGELLA OF RECOMBINANTS OBTAINED BY TRANSDUCTION OF FLAGELLAR ANTIGEN-DETERMINANTS BETWEEN DIPHASIC FLAGELLATED STRAINS

Strain Description	Clone No.	Phase 1 flagella		Phase 2 flagella	
		Antigen	NML	Antigen	NML
S. typhimurium wild-type parent strain	*LT* 2	*i*	+	*1,2,3*	+
S. abony wild-type parent strain	*SW* 803	*b*	–	*e,n,x*	–
S. typhimurium given $H_1{}^b$ from *S. abony*	*SW* 699	*b*	–	*1,2,3*	–

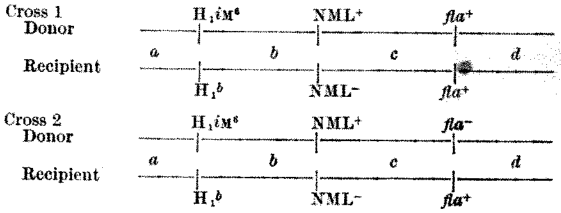
S. typhimurium given $H_2{}^{e,n,x}$, from *S. abony*	*SW* 698	*i*	+	*e,n,x*	+
S. abony given $H_1{}^i$ from *S. typhimurium*	*SW* 933	*i*	+	*e,n,x*	+
S. abony given $H_2{}^{1,2,3}$, from *S. typhimurium*	*SW* 932	*b*	–	*1,2,3*	–

strain concerned in the case of the exceptional, N-methyl-lysine - negative recombinant was found to be itself negative for N-methyl-lysine. By contrast, ten clones of the first type, that is, with antigen *b*, each obtained by transduction of the *fla*$^+$ gene from a N-methyl-lysine - positive strain, were all negative for N-methyl-lysine. These results indicate that the presence or absence of N-methyl-lysine in the flagellar protein of a strain in phase 1 is controlled either by the gene which determines the antigenic character of this protein or by a closely linked gene.

The phase 1 and phase 2 flagellar antigens of diphasic strains are controlled, respectively, by two series of alleles, at loci termed H_1 and H_2, which in phage-mediated transduction appear unlinked[5]. A series of hybrids obtained by transduction of one or other of these genes between flagellated diphasic strains differing both in N-methyl-lysine character and in their phase 1 and phase 2 flagellar antigens were next examined. Table 1 records the results obtained on testing recombinants of a strain of *S. typhimurium* (positive for N-methyl-lysine; flagellar antigens *i* and 1,2,3) and a strain of *S. abony* (negative for N-methyl-lysine; antigens *b* and *e,n,x*); less extensive experiments on other strains gave similar results. It was found: (i) that the antigenically distinct phase 1 and phase 2 flagellins produced by a diphasic recombinant strain were always alike in respect of the presence or absence of N-methyl-lysine; and (ii) that when the phase 1 flagellar antigen of a strain was altered by transduction, the N-methyl-lysine character of the recombinant was always the same as that of the donor strain from which the phase-1 antigenic determinant (H_1) had been transduced; whereas replacement of the phase 2 determinant (H_2) of a strain by transduction from a strain of opposite character had no effect on the N-methyl-lysine character of the recipient strain.

These results indicated that the presence or absence of N-methyl-lysine in the flagellin(s) of a *Salmonella* strain is decided by a genetic determinant which is either closely linked to, or part of, the H_1 locus. To decide between these alternatives, a search was made for re-assortment of phase 1 antigenic character and N-methyl-lysine character during transduction. The recipient strain was a monophasic flagellate strain of *S. paratyphi B* (phase 1 antigen *b*, no second phase) and negative for N-methyl-lysine. Two donor strains were used: in cross 1, a sub-line of *S. typhimurium* strain *LT*2, positive for N-methyl-lysine, diphasic, the phase 1 antigen being *i M*6 (a mutant derivative of *i*: Joys, T. M., unpublished work); in cross 2, a non-motile mutant of the *i M*6 strain, lacking flagella because of mutation at a site closely linked to H_1. Motile transductants with the phase 1 flagellar antigen of the donor strain were selected by inoculating the phage-treated recipient bacteria into semi-solid medium containing sufficient anti-*b* serum to prevent the spread of motile bacteria with antigen *b*. From cross 1 we tested sixteen clones with antigen *i M*6, resulting from transduction of the H_1 locus from the motile donor strain; all were positive for N-methyl-lysine, like the donor strain. From cross 2 we tested ten clones with antigen *i M*6, resulting from incorporation by recipient bacteria of the H_1 gene from the non-motile donor but not the closely linked *fla*$^-$ gene causing its non-motility; eight were positive for N-methyl-lysine, like the donor, while two were negative, like the recipient. This indicates the existence of a locus for N-methyl-lysine character which is closely linked to H_1, but separable from it, probably lying between H_1 and the gene causing absence of flagella in the non-motile donor strain used:



In cross 1 motile transductants with antigen *i M*6 can be produced by incorporation of a single transduced chromosome fragment by one cross-over in region *a* and one in region *b*, *c* or *d*; if *b* is much shorter than *c* plus *d*, then nearly all such transductants will have the N-methyl-lysine character of the donor strain. In cross 2 one cross-over in *a* and one in *b* or *c* are required; if *b* is not very much shorter than *c*, a substantial proportion of the motile recombinants with antigen *i M*6 will have the N-methyl-lysine character of the recipient strain.

Thus the presence or absence of N-methyl-lysine in the flagellar protein produced by bacteria in flagellar antigenic phase 2 is determined by a gene which is not closely linked to the H_2 gene determining the antigenic character of this protein; and in the case of bacteria in phase 1 by a gene closely linked to, but separable from, the H_1 gene determining the antigenic character of the protein produced. The available evidence suggests that *Salmonella* flagella are composed of a single protein. The H_1 and H_2 genes presumably specify not only the antigenic specificities of the phase 1 and phase 2 flagellar proteins but also their complete amino-acid sequences, because flagella of different antigenic types differ in some physical properties, in relative abundance of certain amino-acids and in the peptide 'maps' given by their enzymatic digests (Ambler and McDonough, unpublished results). If this is so, then the control of the presence or absence of N-methyl-lysine in these proteins by a gene other than H_1 or H_2 is in accordance with predicate (*b*) above, that the genetically determined presence or absence of an uncommon amino-acid in a particular protein cannot be controlled by the gene which specifies the amino-acid sequence of this protein. The experimental results are thus compatible with the hypothesis that only twenty different base-groups specifying amino-acids occur in DNA.

The proteins of *Salmonella* other than flagellar protein do not contain N-methyl-lysine in detectable amounts. The gene determining the presence of N-methyl-lysine in flagellin, but no other protein, perhaps causes the production of an enzyme which methylates the ε-amino-groups of certain lysine radicals in flagellin already formed. Experiments to test this hypothesis are being made.

We thank Prof. J. Lederberg and Dr. N. Datta for providing some of the recombinant strains used.

CYTOLOGY OF CELLS WHICH SYNTHESIZE PROTEIN

By M. S. C. BIRBECK and DR. E. H. MERCER
Chester Beatty Research Institute, Institute of Cancer Research, Fulham Road, London S.W.3

THE cells found in glands which synthesize and secrete protein have been very extensively studied by biochemists and cytologists with the object of discovering the cellular processes associated with protein synthesis. In this article we wish to describe and comment on the fine cytology of another, but less-studied, class of cells which synthesize protein. These, in contrast to secretory cells, retain their product within their plasma membrane and do not secrete it. Examples are the cells of the mammalian epidermis which make keratin, the myoblast which forms the muscle proteins and the erythroblast which forms hæmoglobin. For want of a better name we shall call these cells 'retaining cells'. As well as these examples of cells which synthesize specific proteins there are others which have a similar cytoplasmic structure. These are cells with a high rate of growth, for example, animal embryonic cells, plant meristematic tissue, bacteria and many tumours. In these cases the protein synthesized is their own cellular protein.

The Secretory Cell

Examination on the electron microscope of thin sections of secretory cells has revealed in many of them systems of membranes to which are attached numerous dense particles 100-200 Å. in diameter (Fig. 1*a*). The almost simultaneous discovery of these structures by several groups, who each introduced their own terms, has produced a complex nomenclature. The two most commonly used terms, 'endoplasmic reticulum'[1] and 'ergastoplasm'[2], are a source of further confusion, in that, whereas some authors use them to describe membranes with particles, others include those membranes in the cell which are 'smooth' or 'agranular' and are not covered by particles. The presence in the cell of these different types of membranes make us, at least for the present, favour the Sjöstrand nomenclature[3], which defines the particle-covered membranes as 'α-cytomembranes', the external plasma membrane and infoldings of it as 'β-cytomembranes', and the smooth membranes found in the Golgi zone of the cell as 'γ-cytomembranes'. The particles themselves have at least three names (namely, Palade, RNP or microsomal particles). The use of the terms 'microsomes' and 'ribosomes' is inadvisable since these terms are operational terms for specifying biochemical fractions and are not therefore synonymous with morphological structures.

Porter[4] was one of the first to point out the correlation between α-cytomembranes in a cell and basophilia. The integrated biochemical and electron microscopic studies of Palade and Siekevitz[5] showed that α-cytomembranes are the main component of the microsome fraction of the cell, and furthermore that the particles are found in the ribosome fraction. It was therefore inferred that the particles are the site of much of the cytoplasmic ribonucleic acid, the relationship of which to protein synthesis is generally accepted[6,7].

The presence of the particles in these cells is therefore understandable, but the function of the membranes is more obscure. Some have suggested[8,9] that they may provide an interconnected pathway in the cell which is required to guide both raw materials and products of protein synthesis from one site in the cell to another. Inter-connexions between the different membrane systems are occasionally seen; however, evidence that all the membranes are connected (that is, to form a reticulum), which

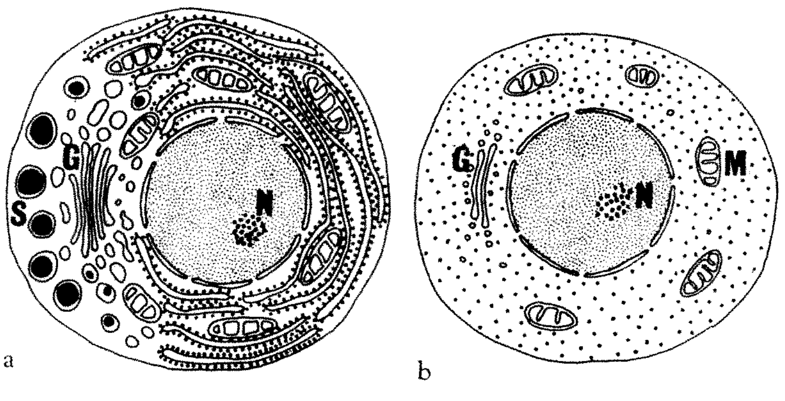

Fig. 1. The fine cytology of the two kinds of cells forming protein: (*a*) the secretory cell, and (*b*) the retaining cell. *M* are mitochondria, *N* nucleoli within the nuclei, *G* clusters of Golgi membranes. The characteristic organelle of the secretory cell is the α-cytomembrane or membrane covered with particles. In the secretory cell the particles are free and there are few α-cytomembranes. In the latter type of cell the synthesized protein appears freely throughout the cytoplasm and is not contained in vesicles

could only be obtained from serial sections, is still lacking. The membranes could also function as a support to localize enzymes[10]; they would represent the cytoskeleton described by Peters[11]. A recent comprehensive review of these structures by Haguenau[12] covers both the microscopical and the biochemical observations.

Nearly all the electron micrographs of these structures have been made after using osmium tetroxide as a fixative, which is particularly satisfactory for delineating both membranes and particles. Other fixatives give different images; for example, permanganate fixation[13] reveals only the membranes, and formalin fixation (unpublished work) shows only the particles; in this latter case the particles are arranged in sheets, so that one would infer that the membranes are preserved but lack sufficient electron density to be visualized. Recent observations by Sjöstrand and Hanzon[14] on frozen-dried tissue have indicated that, after this method of fixation, no particles are seen, but instead a continuous layer of electron-dense material. Assuming that this method of fixation is the most likely to preserve the structure of the living cell, it has been suggested that the particles are an artefact of osmium fixation. However, the similar and regular size of the particles as shown both by electron microscopy and by ultracentrifugation makes it unlikely that they are a random aggregate of material. An alternative explanation would be that the particles extend over a much larger volume in the cell than the micrograph of the specimen fixed with osmium tetroxide would suggest; this would be expected if they had a large degree of hydration.

Retaining Cells

The successful correlation of many structural aspects of secretory cells with biochemical data has tended to obscure the fact that it applies only to this particular class of cells. The other group of protein-synthesizing cells, the retaining cells, prove to have a very different appearance in the electron microscope, for in these the elaborate system of membranes covered with particles (α-cytomembranes) is not present (Fig. 1*b*). Dense particles similar to those found on the α-cytomembranes in secretory cells are numerous, but in retaining cells they are freely dispersed in the cytoplasm. The distribution of particles corresponds to the diffuse basophilia of these cells.

We originally observed that the cells of the hair cortex, where the fibrous protein keratin is synthesized and retained in the cell, had this type of cytoplasmic structure[15]. This led us to study other cell systems which also retain the protein they synthesize. The cells studied are noted in Table 1. From our observations we are able to make some general comments about these cells.

Retaining cells are not devoid of membranes; a nuclear membrane with typical 'pores', and a plasma membrane, are always present. Moreover, a cluster of smooth γ-membranes in the Golgi region of the cell is usually seen. Indeed there is much evidence for regarding this system of membranes as a universal cell structure. However, the characteristic feature of these cells is always the large number of free particles; from this it follows that these particles, which are not necessarily attached to membranes, are the essential cytoplasmic element associated with protein synthesis. Another feature of these cells is that the protein, the product of synthesis, is not enclosed in a membrane; whereas in secretory cells a membrane either encloses the secretory granule or alternatively the protein appears inside the distended vesicles of the α-cytomembranes (*S*, Fig. 1*a*). The absence of limiting membrane in retaining cells is perhaps connected with the fact that the protein does not pass through the plasma membrane.

Table 1

	Type of cell	Product
Cells synthesizing specific protein	Epidermal cells:	
	skin	Keratin
	hair cortex	Keratin
	hair inner root sheath	Keratohyalin
	Erythroblasts	Hæmoglobin
	Developing muscle cells	Actomyosin
Rapidly proliferating cells	Embryonic cells	General cellular protein
	Tumour cells	
	Lymphocytes	
	Meristematic plant cells	
	Bacteria	

The examples of retaining cells in Table 1 may themselves be divided into two classes. The first examples are cells the cytoplasm of which becomes filled with a specific protein. During the period of protein synthesis the cells contain free particles, but eventually the cytoplasm becomes completely filled with the protein and the particles disappear. The resultant cell is a fully differentiated one, and does not afterwards divide. The second group of cells are those with a high rate of cell division; the protein synthesized in these cells is the cellular protein required for growth. This second type of retaining cells includes several groups of cells, which it is convenient to discuss separately.

Embryonic and Tumour Cells

Embryonic cells and ova have a mixed cytoplasmic pattern (Mercer, E. H., and Wolpert, L., unpublished work), both free particles and particles attached to membranes being present. Free particles at first predominate, but as cleavage and differentiation proceed, a separation into secreting and retaining cells emerges. (See also Slauterback and Fawcett[15a].)

Tumour cells may be of either type. Tumours derived from retaining type cells, for example, epidermal carcinomas (Mercer, E. H., unpublished work), have the corresponding cytoplasmic structure. Primary tumours, which are derived from secretory cells and which are sufficiently well differentiated to retain their secretory ability, for example plasma cell tumours[16], contain α-cytomembranes. Those tumours, however, although perhaps originally well differentiated, that have lost their secretory ability, are of the retainer type[17]. These would include most of the anaplastic animal tumours maintained by serial grafting, both in the solid and in the ascites form, as our own work has shown (Mercer, E. H., and Easty, G. C., unpublished work). This reversion of tumour cells to the cytoplasmic pattern of embryonic cells correlates with many of their other properties.

Plant Tissues

Plant meristem tissue contains high concentrations of free particles[18] and may thus be regarded as of the retaining-cell type. Some reports[19,20] claim the presence of endoplasmic reticulum, but the use of this all-inclusive term fails to make clear whether the authors refer to α-membranes covered with particles or γ-membranes with smooth surfaces. Our own observations (Mercer, E. H., and Mercer, F. V., unpublished work) on developing root tips (maize) reveal small amounts of α- and γ-cytomembranes in some cells, suggesting that initially the cell cytology is generalized. Because plant cells do not commonly secrete protein, the absence of α-cytomembranes is to be expected; their occurrence in those rare plant cells which do secrete would be added corroboration of their required presence in secretory cells. We have examined (with Prof. W. O. James and Dr. R. M. Leach, Botany Department, Imperial College) the scutellum of germinating barley seeds. These cells produce the enzymes required for the breakdown of the endosperm. Our results show that the cytoplasm of these cells has an appearance nearer that of animal secretory cells than that of typical plant cells. Membranes covered with particles are present, although some free particles exist also.

Bacteria

Recent electron micrographs of bacteria[21,22] show free particles embedded in the dense amorphous cytoplasmic region of the cell. It is possible that the particles are smaller than those in animal cells, but the good correlation between these particles and the isolated ribosomes[23] is sufficient to regard them as a site of RNA in the cell and therefore analogous to the particles in animal cells. Bacteria therefore have the cytoplasmic pattern of retaining cells, although their cytology in other respects is very different: the absence of a nuclear membrane and of mitochondria is most obvious. Brieger *et al.*[24] have described membranes in some Mycobacteria, but these are of the smooth type. Although the presence of free particles agrees well with the rapid growth-rate of bacteria, the absence of membranes makes it difficult to explain bacterial secretion. That enzymes do appear in the extracellular medium is undoubted; either the mechanism of secretion must differ from that in animal cells or perhaps extracellular protein is liberated by lysis of the whole cell. This latter method of 'holocrine' secretion does occur in bacteria[25], but evidence that it is the only mechanism is lacking.

Protozoa

Many Protozoa contain elaborate organelles based on membranes, as might be expected from their complex intracellular differentiation. Two types of amœba studied by us are of interest. *A. proteus* has organelles based on smooth γ-membranes, but no α-cytomembranes[26]. The social amœbæ, *Dictyostelium* and *Polyspondylium*, which from their elaborate life-histories might be expected to secrete, have small amounts of α-cytomembranes[27].

Other Implications

The belief that all cells have an internal structure resembling that of the secretory cell is largely responsible for the speculation that all the membranes of the cell are interconnected to form a single system. The external plasma membrane may also be included in this system[28]. While this speculation is supported by evidence that all membranes have a common phospholipid-protein structure, and while transient interconnexions probably do occur, it is difficult to believe that there are any permanent interconnexions in retaining cells. The connexion between the cytoplasmic membranes and the nuclear membrane has been regarded as a means[29] by which nuclear RNP particles are transferred to the cytoplasm. The absence of this connexion in retaining cells, which nevertheless have a fenestrated nuclear membrane similar to that of secretory cells, makes it likely that some other mechanism of transfer of RNA must exist.

While nearly all the protein-producing cells yet examined belong to either of the two types we have described, we would not wish to imply that they represent the only two possibilities. In at least one tissue[30], the colleterial glands of the cockroach, part of which synthesizes an oxidase required to tan the structural protein of the egg case, there is a possibility that the enzyme is produced by mitochondrial proliferation. If this were so, it would be similar to the protein synthesis which occurs in mitochondria[31], which does not appear to contain RNP particles.

LETTERS TO THE EDITORS

RADIOASTRONOMY

Secular Variation of the Flux Density of the Radio Source Cassiopeia A

In 1951, Ryle and Elsmore[1] reported on a series of observations of radio sources using an interferometer at a frequency of 81·5 Mc./s. A comparison of the flux densities of about one hundred sources measured nearly every day for eighteen months revealed no long-term variations greater than 10 per cent, or for some of the more intense sources, greater than 5 per cent.

It is now believed that the majority of sources are extra-galactic and would therefore not be expected to show any intrinsic variations over a few years only. A number of sources, however, have been identified with the remnants of galactic supernovæ of comparatively recent origin, and Minkowski[2] has shown that the intense source Cassiopeia A is probably of this type. Optical study of this source is difficult because of heavy obscuration in the region, but his measures of the velocities of the faint visible filaments suggest that the supernova exploded 258 ± 14 yr. ago. There is clearly the possibility of being able to detect a change in the intensity of this source.

Some observations for this purpose were carried out in Cambridge in 1956 with apparently positive results, but it was felt that further confirmation was required. This has recently been obtained and reveals that the flux density is decreasing by about 1 per cent per annum. Similar measurements are also in progress at the U.S. National Radio Astronomy Observatory, Green Bank (J. Findlay, private communication), at a frequency of 1,420 Mc./s.

Absolute measurements of flux density are not easy, but fortunately the flux density of Cassiopeia A (at $\alpha = 23$h. 21m., $\delta = +58° 32'$) may readily be compared with that of Cygnus A (at $\alpha = 19$h. 58m., $\delta = +40° 36'$), since these sources are the strongest two at metre wave-lengths and are not far distant from one another in the sky. Cygnus A has been identified with a pair of colliding galaxies and its flux density is not likely to change appreciably in a time small compared with that taken by radio waves to traverse the source itself—say 10^5 years.

The same aerial[3] has been used for all the observations, which have been at a frequency of 81·5 Mc./s. It is a fixed transit instrument consisting of two broadside arrays, each measuring 10 × 1 wave-lengths, separated by 100 wave-lengths on an east–west axis. The reception pattern of each aerial is therefore restricted to ± 3° in an east–west plane, but covers about ± 45° in the north–south plane. There are three sets of observations, one in December 1948 and January 1949, one in November 1956 and one in December 1960. The receiver used for the first two series was a total-power receiver of the type developed by Machin, Ryle and Vonberg[4] and for the third series, a phase-switching receiver[5]. In each case, records showing obvious signs of scintillations have been discarded, leaving records of 14, 10 and 13 days, respectively.

Table 1

Date	Mean ratio of observed record amplitudes Cassiopeia A/Cygnus A	Standard error of mean
December 1948 January 1949	1·751	± 0·024
November 1956	1·635	± 0·019
December 1960	1·536	± 0·017

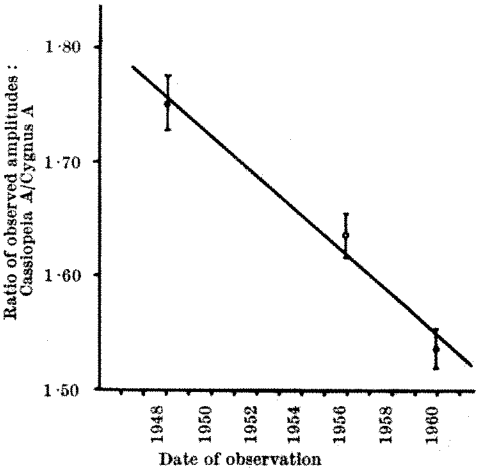

Fig. 1. A plot of the mean ratios of observed amplitudes of records of the radio sources Cassiopeia A and Cygnus A as a function of time. The vertical lines indicate standard errors

Table 1 gives the averages of the ratios of observed record amplitudes of Cassiopeia A and Cygnus A for the three sets of observations and in Fig. 1 they are plotted against the dates of the observations. The standard errors of the averages of the ratios are indicated on the plot. It should be noted that the ratios have *not* been corrected for the aerial polar diagram.

Unless some unknown systematic error varying with time is involved, there is very strong evidence for a change in the relative flux densities of Cassiopeia A and Cygnus A. If it is assumed that the flux density of the latter source has remained constant, then a least-squares solution for the best straight line through the points indicates a decrease in the flux density of Cassiopeia A of (1·06 ± 0·14) per cent per annum.

A number of possible sources of error are eliminated by the use of the same aerial system for all the observations. Some others that have been considered include non-linearity of the receivers, effects of a variation of output time constant (since the periodicities of the interference fringes of Cygnus A and Cassiopeia A differ) and changes in the polar diagram of the arrays. None is thought to be sufficient to account for the observed change of ratio. The effect of the increase of the angular size of the Cassiopeia A source with time is quite negligible.

Shklovsky[6], assuming that the radio radiation is due to the synchrotron mechanism, has made a theoretical prediction that the present yearly fractional change of the flux density of Cassiopeia A is :

$$\frac{\Delta S_\nu}{S_\nu} = -\frac{\beta}{\text{age in years}}$$

where $\beta = 2(1 + 2\alpha)$ and α, the spectral index, is given by: $S_\nu \propto \nu^{-\alpha}$. If $\alpha = 0{\cdot}8$ and the age is 258 yr., then:

$$\frac{\Delta S_\nu}{S_\nu} \simeq -2 \text{ per cent}$$

which is remarkably close to the observed figure. Some of his assumptions are debatable and it would not seem difficult to modify them to obtain an even closer agreement. Shklovsky's argument involves a constant energy spectrum for fast electrons and a magnetic field inversely proportional to the square of the nebular radius. This implies that the fractional change will be independent of frequency, as seen above, since β for Cassiopeia A is independent of frequency[7]. It will be interesting to see if observations at other frequencies confirm this.

In conclusion, the obvious point must be made that Cassiopeia A should no longer be considered as a standard source for the measurement of flux densities.

We thank Prof. M. Ryle for the loan of the records taken during the period December 1948–January 1949.

RADIOPHYSICS

A New Method for the Calculation of *N*(*h*) Profiles from Ionospheric *h*′(*f*) Curves

RECENTLY[1-4], a lamination method has been developed for the calculation of electron density-height profiles ($N(h)$ profiles) from ionospheric virtual height-frequency curves ($h'(f)$ curves) with an electronic digital computer.

This method includes the evaluation of integrals of the 'group refractive index' μ' of the radio waves in the ionosphere. Generally, μ' is related to the (phase) refractive index μ through the equation:

$$\mu = \mathrm{d}(f\mu)/\mathrm{d}f \qquad (1)$$

where μ' and μ are functions of the frequency f of the wave and the electron density $N(h)$ in the ionosphere, which is a function of the height h above ground.

According to the magneto-ionic theory, μ is given, under the influence of the Earth's magnetic field $\mathbf{H}_0$, by the Appleton–Hartree formula as[5]:

$$\mu^2 = 1 - \frac{X}{1 - \frac{1}{2}Y_T^2/(1-X) + [Y_T^4/4(1-X)^2 + Y_L^2]^{1/2}} \qquad (2)$$

for the ordinary wave, where

$X = f_0^2/f^2$, $Y = f_H/f$, $Y_T = Y \sin\theta$, $Y_L = Y \cos\theta$, and θ is the angle between the wave normal and $\mathbf{H}_0$, ($|\mathbf{H}_0| = H_0$). $f_H (= e\mu_0 H_0/2\pi m)$ and $f_0 (= [Ne^2/m\varepsilon_0]^{1/2}/2\pi)$ are the gyro-frequency of an electron and the plasma frequency in the ionosphere in M.K.S. units.

An ionospheric $h'(f)$ curve for the ordinary wave is given by:

$$h'(f) = \int_0^{h_r} \mu'(f, f_0(h))\mathrm{d}h \qquad (3)$$

where $f_0(h)$ is used instead of $N(h)$ in μ', and h_r denotes the level where the wave is reflected, $f_0(h_r) = f$.

Assuming that $f_0(h)$ is a monotonic function of h, equation (3) becomes:

$$h'(f) - h_0 = \int_0^f \mu'(f, f_0)(\mathrm{d}h(f_0)/\mathrm{d}f_0)\mathrm{d}f_0,\ 0 \leqslant f_0 \leqslant f \qquad (4)$$

h_0 is the level where $f_0(h_0) = 0$, or $N(h_0) = 0$.

Equation (4) is the starting-point of the lamination method[1].

Since formula (2) for μ is rather complicated and μ' is related to μ by equation (1), the evaluation of integrals of μ' seems, even by the use of an electronic computer, very elaborate[4].

To avoid this difficulty, I have devised an improved method for the calculation of $N(h)$ profiles.

Integrating both sides of equation (4) with respect to f, over the range of $0 \leqslant f \leqslant f_1$:

$$\int_0^{f_1}[h'(f) - h_0]\mathrm{d}f = \int_0^{f_1}\mathrm{d}f \int_0^f \mu'(f, f_0)(\mathrm{d}h(f_0)/\mathrm{d}f_0)\mathrm{d}f_0 \qquad (5)$$

and changing the order of integration in the right side of equation (5):

$$= \int_0^{f_1}\mathrm{d}f_0(\mathrm{d}h(f_0)/\mathrm{d}f_0)\int_{f_0}^{f_1}\mu'(f, f_0)\mathrm{d}f$$

According to equation (1), the integral in the above expression is:

$$\int_{f_0}^{f_1}\mu'(f, f_0)\mathrm{d}f = f\mu(f, f_0)\Big|_{f_0}^{f_1} = f_1\mu(f_1, f_0) - f_0\mu(f_0, f_0)$$

Since $\mu(f_0, f_0) = 0$ by equation (2), equation (5) reduces to:

$$\frac{1}{f_1}\int_0^{f_1}[h'(f) - h_0]\mathrm{d}f = \int_0^{f_1}(\mathrm{d}h(f_0)/\mathrm{d}f_0)\mu(f_1, f_0)df_0$$

Or, putting

$$\frac{1}{f_1}\int_0^{f_1}h'(f)\mathrm{d}f = g(f_1),\ \text{and}\ f_1 \to f,$$

we obtain:

$$g(f) - h_0 = \int_0^f (\mathrm{d}h(f_0)/\mathrm{d}f_0)\mu(f, f_0)\mathrm{d}f_0 \qquad (6)$$

where $g(f_1)$ is then the average of $h'(f)$ within $0 \leqslant f \leqslant f_1$.

Equation (6) is equivalent to equation (4) and can be used for the calculation of $N(h)$ profiles after the same manner as the above-mentioned lamination or matrix method[1]; but equation (6) contains the integral of μ instead of μ' in equation (4), so the programming for an electronic computer by equation (6) will be, we believe, much easier than that of equation (4).

It should be noted that this method can also be used for the $h'(f)$ curve of the extraordinary wave.

Furthermore, as f approaches critical frequency f_c, the virtual height $h'(f)$ tends to increase infinitely and $h'(f_c)$ is often indefinite; but, if:

$$g(f_c) = \lim_{f_1 \to f_c}(1/f_1)\int_0^{f_1}h'(f)\mathrm{d}f$$

converges, the height of maximum electron density $h(f_c)$ can be determined by equation (6).

Physically speaking, if the $N(h)$ profile has a definite maximum point, $g(f_c)$ will converge; and vice versa.

μ' has the property that $\mu'(f_0, f_0) \to \infty$, but $\mu(f_0, f_0) = 0$; and this may be related to the properties of $h'(f_c)$ and $g(f_c)$. For example, if an approximation of $h'(f) \doteqdot A/(f_c - f)^m$ is valid near the critical frequency f_c, where A and m are constants greater than 0, $g(f_c)$ converges if $1 > m \geqslant 0$, but $h'(f_c)$ tends to infinity.

Since $g(f)$ in equation (6) should be a monotonic function of f, $h'(f)$ should also be monotonic; therefore, this method cannot be applied for an $N(h)$ profile which has a 'valley' in the electron density.

The scaling error ε of the $h'(f)$ curve would be given by:

$$\varepsilon = h'(f)_{\text{scaled}} - h'(f)_{\text{true}} = \delta h' + (\mathrm{d}h'(f)/\mathrm{d}f)\delta f \qquad (7)$$

where $\delta h'$ and δf are the height and frequency errors which are proper to the quality of the $h'(f)$ record, and are considered to be random variables.

Simpson's numerical integration method[6] will be adequate for the calculation of $g(f)$ from the scaled values of $h'(f)$, and if a sufficiently large number of n-points (including the value of h_0) are scaled from an $h'(f)$ record between $f = 0$ and $f = f_1$ near f_c, the relative error of $g(f)$ will decrease proportionally to the inverse square root of n. On the other hand, the $h'(f)$ curve then can be represented, for example, through the Lagrangian interpolation formula[6], by a polynomial of degree $(n - 1)$, passing through these n-points, by:

$$h'(f) = \sum_{m=0}^{n-1} a_m f^m, \quad 0 \leqslant f \leqslant f_1 \qquad (8)$$

Then:

$$g(f) = \sum_{m=0}^{n-1} a_m f^m/(m + 1)$$

so the component of degree m in $g(f)$ is diminished by a factor of $1/(m + 1)$, which is of higher order than the factor $1/n^{1/2}$ of the relative scaling error of $g(f)$.

This defect, however, seems to be offset by the property of $g(f)$, which is rather insensitive to the possible large scaling error of the $h'(f)$ record near the critical frequency f_c owing to a large value of $\mathrm{d}h'(f)/\mathrm{d}f$ in equation (7); and the behaviour of $h'(f)$ near f_c is, probably, responsible for the terms of higher degrees in equation (8).

Further details of this work will be reported elsewhere.

PHYSICS

Influence of an Electric Field upon the Heat Transfer from a Hot Wire to an Insulating Liquid

If a non-uniform electric field is applied to a medium of dielectric constant K_1, containing a region of lower dielectric constant K_2, the latter will experience a force directed towards the region of lower field strength. This force is proportional to the difference between the two dielectric constants and the gradient of the square of the electric field. Now, when a liquid is heated, and expands, there is a resultant fall in dielectric constant, so that if the heating occurs in a region of high field, the heated liquid should be forced into regions of lower field strength.

In a recent experiment, we have been able to show that this effect can be used for enhancing the rate of heat transfer between a heated wire and an insulating liquid in which the wire is immersed.

The apparatus consists of a coaxial cell, in which the hot wire, which is at ground potential, is surrounded by a cylindrical electrode, to which the high voltage is applied. Measurements of the current flowing through the wire and the voltage drop along it are used for determining both the temperature of the wire and the power input. Under equilibrium conditions (attained in a few seconds), the heat input to the wire becomes identical to the heat transferred from the wire to the liquid.

The results given in Fig. 1 were obtained using hexane as the working fluid; the central electrode was a 0·1-mm. diameter nickel wire, and the outer electrode was a 3-cm. diameter nickel cylinder, 10 cm. in length.

In Fig. 1, the upper curve corresponds to conditions of zero applied field, and shows the loss of heat from the horizontal wire due to natural convection;

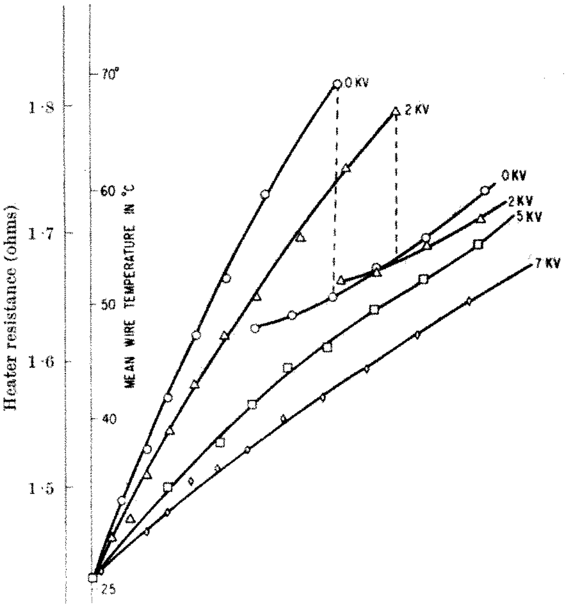

Fig. 1. Heat transfer from a 0·1-mm. diameter, horizontal nickel wire in n-hexane. Wire temperature versus power input for applied voltages of zero, 2, 5 and 7 kV., d.c. Ambient temperature 26° C.

the sudden break in the curve, at a power input of about 10 W., corresponds to the onset of boiling.

When a d.c. potential of a few kV. was applied between the wire and the cylinder, there was a fall in the temperature of the wire, as can be seen from the curves (Fig. 1), indicating a considerable enhancement of the heat transfer coefficient. (For example, below the region of boiling heat transfer, in going from zero to 5 kV., the mean temperature rise of the wire was approximately halved, indicating a doubling of the heat transfer coefficient.)

It is interesting to note that in the region of boiling heat transfer, bubbling of the liquid around the wire could be suppressed by application of the field; as can be seen from Fig. 1, this results in a decrease in heat transfer coefficient in going from zero to 2 kV.—though this effect is restricted to the immediate vicinity of the onset of boiling.

The results shown in Fig. 1 were obtained with a positive applied high voltage, but virtually identical results were found with a negative voltage. This observation is consistent with the initial assumption that the effect is an electrostatic one, and shows that the interactions between the electrostatic field and ions in the liquid play a negligible part in this phenomenon.

Electron Microscopy of Crystal Lattices: an Anomalous Effect

AN explanation of intensity modulations in electron micrographs of crystal lattices[1] has recently been given by Labaw[2], and Hashimoto, Naiki and Mannami[3] have published a theoretical interpretation of fringe separation modifications which occur when a Bragg extinction contour lies in the same direction as the crystal 'lattice planes' resolved. The present communication deals with the conditions which exist when a Bragg extinction contour lies across the lattice planes in question. A theory given by Cowley and Moodie[4] is used to interpret a phenomenon which has recently been observed in practice (see Fig. 1).

Two strong beams only, the incident and one diffracted beam, are considered to have amplitudes U_0 and U_h respectively in the crystal. Then:

$$U_0 = [\cos\omega H - i(\pi\zeta_h/\omega)\sin\omega H]\exp\{i\sigma HE_0 - \rho HG_0 + \pi i\zeta_h H\} \qquad (1)$$

$$U_h = iF_h(\sin\omega H/\omega)\exp\{i\sigma HE_0 - \rho HG_0 - \pi i\zeta_h H\} \qquad (2)$$

where F_h is a structure factor:

$$F_h = \sigma E_h + i\rho G_h$$

and:

$$\omega = (\pi^2\zeta_h^2 + F_h F_{\bar{h}})^{1/2} \qquad \text{(see ref. 4b)}$$

In these equations, H is the crystal thickness and ζ_h is a factor representing the deviation from the Bragg angle, being the separation between the sphere of reflexion and the reciprocal lattice point given by h. In the Bethe[5] terminology, ζ_h is called the excitation error.

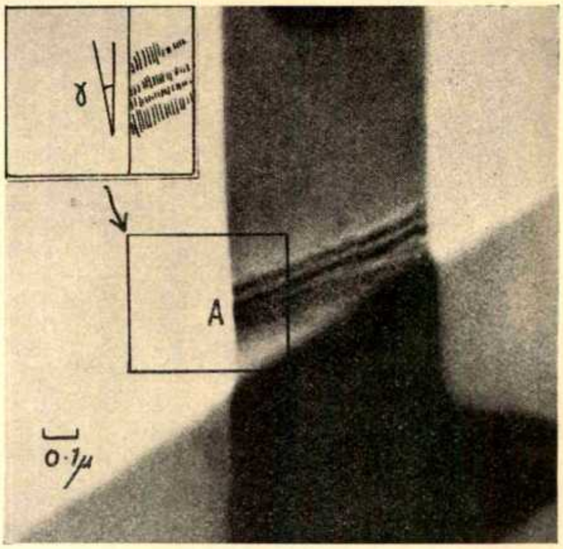

Fig. 1. Electron micrograph of a crystal of platinum phthalocyanine overlying a second crystal. $20\bar{1}$ fringes are resolved at *A* on the Bragg extinction contours. The inset is a diagrammatic representation of the area marked

Equations (1) and (2) enable one to obtain the intensity distribution at the exit face of the crystal:

$$\psi\psi^* = |U_0 + U_h\exp\{-2\pi ihx/a\}|^2$$

that is,

$$\psi\psi^* = 1 - 2|F_h|\frac{\sin\omega H}{\omega}\left(\cos^2\omega H + \frac{\pi^2\zeta_h^2}{\omega^2}\sin^2\omega H\right)$$
$$\cos 2\pi\left(\frac{hx}{a} - \zeta_h H - \alpha\right) \qquad (3)$$

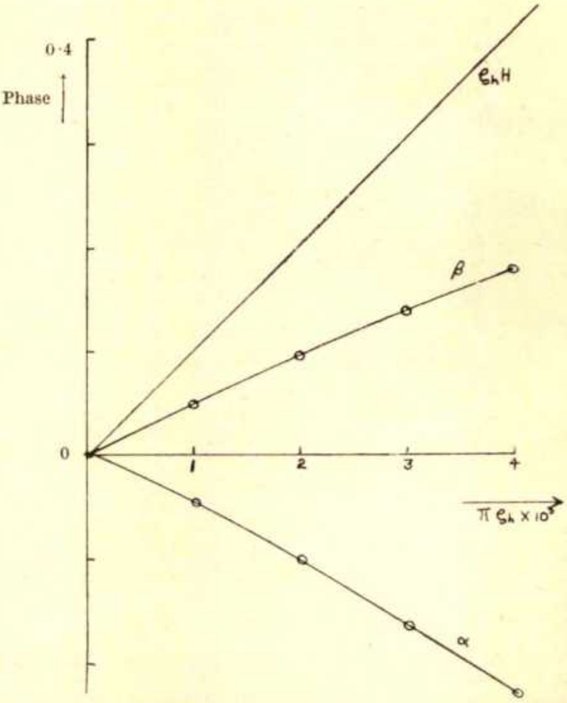

Fig. 2. Graph to show the relationships between α, β, $\zeta_h H$ and ζ_h for values of ζ_h up to $\frac{4}{\pi} \times 10^{-3}$. $F_h H = \pi/2$ and $H = 200\pi$ Å.

and then:

$$2\pi\alpha = \tan^{-1}\left\{\frac{\sigma E_h \cos\omega H - (\pi\zeta_h/\omega)\rho G_h \sin\omega H}{\rho G_h \cos\omega H + (\pi\zeta_h/\omega)\sigma E_h \sin\omega H}\right\} \qquad (4)$$

Of importance in equation (3) is the cosine term in x and the associated phase factor $\beta = (\zeta_h H + \alpha)$. The cosine term gives rise to the periodic undulations of intensity which are made visible when a microdensitometer, for example, is made to scan across several fringes. The phase term β, however, can in some circumstances lead to an anomalous effect, where the fringes lie at a considerable angle γ to the true lattice plane direction. In Fig. 1, the fringes at A make an angle of $\gamma \sim 8°$ with the parallel sides of the crystal. This effect can be predicted theoretically with the two-beam theory if representative values are chosen for H and F_h (see ref. 4*b*) and calculations of α and β made for specific values of excitation error ζ_h. Fig. 2 shows the results of such a calculation. The effect of adding the α curve to the $\zeta_h H$ line certainly leads to a β curve of reduced slope, but the graphs do not mutually cancel. The fact that the final curve has a finite slope implies a continuously changing phase factor as the excitation error increases to a value of $4/\pi \times 10^{-3}$ and, in this range, this must necessarily mean that the fringes are not parallel with the crystal sides.

It is to be concluded that, although fringe spacings in a perfect crystal are indicative of the actual separations of molecular planes[6], both the separation and the direction of fringes at or near a Bragg extinction contour must be treated with reserve.

I thank Dr. F. P. Bowden for help and encouragement, Drs. J. W. Menter, V. E. Cosslett and M. J. Whelan for discussion, and Imperial Chemical Industries, Ltd., for crystal specimens.

Magnetic Energy

I WOULD like to comment, if rather tardily, on one paragraph of Prof. Ferraro's review[1] of my book, *Electromagnetism and Relativity*[2]. He says: "Prof. Cullwick appears to be under a misapprehension about the nature of the magnetic energy of a system of electric currents . . . we read that 'the hypothesis is introduced that the magnetic energy of a current circuit is the same as the kinetic energy of the effective conduction electrons, by virtue of their mean velocity along the wire'. The author then derives from this hypothesis a linear relation between the magnetic vector potential and the mean velocity of the charges . . . the hypothesis appears to be rather misleading. It is used in the chapter on superconductors to derive the familiar equations due to F. and H. London. Here the application is legitimate and indeed the linear relation mentioned above was first derived in connexion with the phenomenological theory of superconductors. But the relation cannot be universally true since it would seem to carry with it the implication that all conductors are superconductors".

From this, it would appear that Prof. Ferraro regards my hypothesis as leading to a macroscopic theory of superconductors identical with that of F. and H. London. This is not so. The hypothesis is that the magnetic energy of a quasi-steady conduction current is *in fact* the kinetic energy of all the conduction electrons which happen to be current carriers (that is, contributing to the macroscopic magnetic field) at a given instant, the effective electronic mass, m, including both the intrinsic mass and the mutual mass corresponding to the mutual electrokinetic energy of the electron with all the other effective conduction electrons in the circuit. The effective mass m will therefore depend on the configuration of the circuit, as does the coefficient of self-inductance, and will not have a constant value across the section of a finite conductor. If $\mathbf{A}$ is the component of the total vector potential due to the current in the single circuit considered, the hypothesis is, in general, summed up in the equation:

$$m\, v = e\, A_v \qquad (1)$$

so that in cases in which A and v are parallel:

$$m\, \mathbf{v} = e\, \mathbf{A} \qquad (2)$$

(In the first edition of my book equation (2) was used, incorrectly, in place of equation (1), which will be found in the second edition, p. 247.)

This is not part of the London theory of superconductors. The latter gives, for conductors large compared with the depth of penetration of the supercurrent, equality between the kinetic energy density of the supercurrent and the energy density of the magnetic field[3]; but these energies are regarded as separate and additive. For stationary conditions in an isolated singly connected superconductor, the London theory gives:

$$m\, \mathbf{v} = -e\, \mathbf{A} \qquad (3)$$

where $\mathbf{A}$ is the total vector potential and m the intrinsic electronic mass, which is not the same as equation (2).

In order to prevent further misunderstanding it is, I think, relevant to add some general comments.

(*a*) The magnetic energy of a current is a physical reality, not merely a mathematical fiction. Maxwell's general view of it has never been contested: "since we can form no conception of an electric current except as a kinetic phenomenon, its energy must be kinetic energy, that is to say, the energy which a moving body has in virtue of its motion. . . . We are therefore led to inquire whether there may not be some motion going on in the space outside the wire, which is not occupied by the electric current, but in which the electromagnetic effects of the current are manifested"[4a].

(*b*) Maxwell regarded magnetic energy as kinetic energy in the universal medium or æther: "According to our hypothesis, we assume the kinetic energy to exist wherever there is magnetic force, that is, in general, in every part of the field . . . and this energy exists in the form of some kind of motion of the matter in every portion of space"[4b].

(*c*) H. A. Lorentz's modification of Maxwell's theory, which when combined with the Lorentz transformation is universally accepted to-day, involves an immobile æther which is therefore incapable, by itself, of possessing kinetic energy. The theory retains, however, Maxwell's original assumption that an electric current *per se* has no inertia, an assumption since proved by experiment to be incorrect.

(*d*) One may then legitimately ask, of those who reject my hypothesis: "What *is* magnetic energy ?".

(*e*) Since an electron can be transformed, by collision with a positron, into electromagnetic radiation, it is reasonable to take its mass as being entirely electromagnetic, although as yet the only microscopic explanation of this is the unsatisfactory one in which classical theory is applied to the external field of a billiard-ball model.

(*f*) In modern theories of conduction the electron is treated in an over-simplified way. It is electrically charged, it is true, but its magnetic properties are largely ignored (an exception is L. Brillouin, *Helv. Phys. Acta*, **7** (Supp.), 47 (1934)). Its kinetic energy is somehow regarded as 'mechanical'. The logical deduction from this is that, when free electrons are accelerated in a vacuum to high energies, their kinetic energy eV is mechanical not magnetic, so that, contrary to all accepted theory, moving charges do not cause a magnetic field.

(*g*) If two electrons, macroscopically coincident, are moving in opposite directions with equal velocities, they cause no resultant macroscopic magnetic field. In a conductor carrying no current it is accepted, in modern theories, that the conduction electrons have random velocities with a Fermi-level of the order of 10^6 metres per sec. When an electric field is applied, almost all the conduction electrons continue to have paired velocities so that their macroscopic magnetic field is nil, but an extremely small proportion attain energies which are not balanced by electrons moving in the opposite direction. The macroscopic magnetic field must therefore be due to this very small proportion of electrons, moving with high velocities.

(*h*) The mechanism, possibly quantized, whereby an applied electric field imparts energy to the conduction electrons is unknown, and the hypothesis, based on a free electron gas, that every conduction electron has its energy changed by a small amount according to classical mechanics may well be entirely wrong. I have shown that if the magnetic field is due to a very small proportion of the available conduction electrons, moving with high velocities, their kinetic energy, even if m is taken to be equal to m_0, is of the same order of magnitude as the magnetic energy in typical current circuits.

(*i*) In my hypothesis the mass of a conduction electron is not to be considered as being limited to the 'particle'. It is the electron's share of the mass of the total electromagnetic energy, both internal and external, of all the current-carrying electrons in the circuit, and must be regarded as extending throughout the electromagnetic field. It thus satisfies Maxwell's general hypothesis quoted in (*a*) above. If the current is steady, this electromagnetic energy is considered to move with the same mean velocity as the electrons. There is no universal material medium through which electromagnetic energy can move only with the speed of light; but when the current changes, then the consequent disturbance of the steady conditions is communicated to a distant element of the field with the velocity of radiation.

[4] (*a*) Maxwell, J. C., *A Treatise on Electricity and Magnetism*, **2**, §552 (third ed., 1892); (*b*) *ibid.*, §636.

PROF. CULLWICK has directed attention to an incorrect statement, which I regret, in my review of the first edition of his book *Electromagnetism and Relativity*. As he says, the fundamental relation derived from his hypothesis (equation (1) of his communication) differs in sign from that usually adopted in the theory of superconductors so that Prof. Cullwick's hypothesis cannot be identified with the former—contrary to my statement.

My error, however in no way invalidates my contention that Prof. Cullwick's hypothesis is misleading. In the first instance, the relation $m\mathbf{v} = e\mathbf{A}$ is itself misleading, since it implies that the mean velocity of the conduction electrons is in all cases in the direction of the local vector potential. This is certainly not true, and in the second edition of his book the author has modified this relation in an attempt to overcome its shortcomings. Secondly, and this was my main contention, the hypothesis is misleading since in no sense can the magnetic energy be identified with the kinetic energy of the effective conduction electrons. In fact, the former is field energy propagated with the speed of light, and so cannot be identified with mechanical energy of the motion of the electrons. In any event, I cannot see what useful purpose such an identification would serve. In Maxwell's dynamical theory of electric currents a useful formalism is developed along the lines of Lagrange's analytical dynamics in which the magnetic energy of the electric current is shown to be the 'analogue' of the kinetic energy in a mechanical system. There is no implication that the two forms of energy are of the same nature. (In fact, Maxwell took care to call the energy of the currents 'electrokinetic' energy.) Any attempt to make it so appears to be a retrograde step, since most of the inertia associated with a system of currents is of electromagnetic origin. The artificiality of this hypothesis becomes, moreover, apparent when one considers that the definition of the inertia of the conduction electron would depend on the particular distribution of currents and on the position of the electron at any instant—surely a curious result.

METALLURGY

Some Properties of Scandium Metal

SCANDIUM is one of the metals being used in an investigation into the alloying behaviour of plutonium with the metals of Group III which is being conducted at this Establishment. Since there is only limited published information on the properties of scandium itself, some experiments were undertaken on the metal. Recently, Spedding *et al.*[1] have reported some work with which the present results are in general agreement.

Thermal analysis, electrical resistance and X-ray diffraction techniques were employed for examination of the behaviour of the metal between room temperature and its melting point. The scandium was of reasonable purity, the main impurities being tantalum $\leqslant$ 0·1 wt. per cent, copper $\leqslant$ 200 p.p.m., silver $\leqslant$ 100 p.p.m., iron $\leqslant$ 20 p.p.m. and combined rare earths $\leqslant$ 100 p.p.m.

For thermal analysis measurements, a platinum-wound furnace was used and was filled with nitrogen at a pressure of 1/3 atm. to prevent volatilization of the scandium at high temperatures. A measuring platinum/platinum–rhodium thermocouple in a closed alumina sheath was in contact with approximately 1 gm. of scandium in a tantalum crucible. During initial runs, the metal when molten attacked the alumina, and a thin tantalum sheath was therefore placed over the end of the alumina for subsequent runs; at this point, the original scandium was replaced by a fresh specimen.

Thermal analysis arrests were invariably weak; but the observed melting point was cross-checked by noting the temperature at which the sheathed thermocouple could be pushed into the scandium during the initial run. The average value obtained for the melting point was 1,522 ± 5° C. However, an analytical check (Phillips, G., and Birks, F. T., private communication) showed that the sample had picked up an appreciable amount of tantalum, in agreement with an observation by Spedding[1]; nevertheless the value obtained does not differ greatly from that of 1,539 ± 2° C. observed by Spedding. A second arrest was observed at 1,373 ± 10° C., which may correspond to one observed at 1,335° C. by the American workers (Spedding, F. H., private communication). Owing to the high transition temperature, it was not possible to determine the crystal structure of the high-temperature modification with the available powder camera, but by analogy with certain of the rare earth elements it might be expected to be body-centred cubic[2].

The initial runs, in which an unprotected alumina sheath was used for the thermocouple, gave a value of about 1,490° C. for the melting point, suggesting that aluminium lowers the melting point of scandium.

Electrical resistance measurements were carried out on a short length of 0·040 in. diameter wire, which had been extruded using a pressure of 10 tons/sq. in. at 600° C. Current and potential leads were provided by spot welding 0·020 in. diameter platinum wires to the sample. The wire was then mounted in a vacuum furnace and the resistance recorded continuously as the temperature was raised; the method used has been described elsewhere[3].

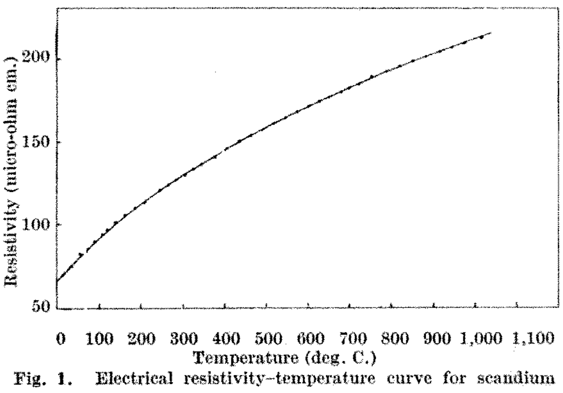

Fig. 1. Electrical resistivity–temperature curve for scandium

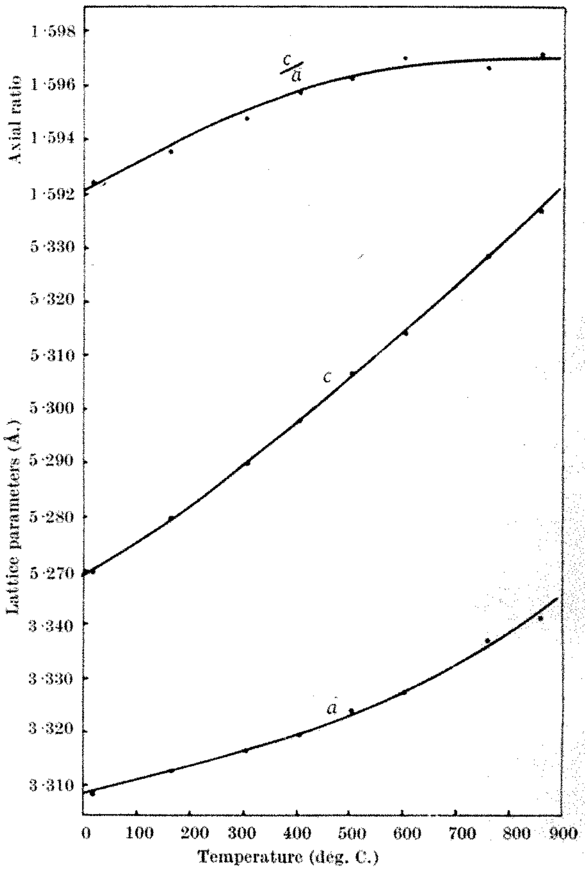

Fig. 2. Variation of scandium lattice parameters with temperature

During successive cycles measurements were taken to steadily higher temperatures; in the final cycle, the electrical contact failed at 1,160° C. On demounting the specimen it appeared that the failure was due to the formation of a low melting-point alloy at the contact points, implying that platinum markedly reduces the melting point of scandium. The resistance measurements at temperatures between 1,050° C. and 1,160° C. were variable, probably due to alloying, and the results shown in Fig. 1 have therefore been cut off at 1,050° C. There is no sign of any phase change taking place in the temperature-range 40–1,050° C., which is in agreement with the thermal analysis data. The 25° C. value of the resistivity was 72 micro-ohm cm., which is much greater than that of the common metals but is in reasonable accordance with the values for the rare earths, most of which lie in the range 55–75 micro-ohm cm. at 25° C.[2]. Previous investigators have given a figure of 66·6 micro-ohm cm. for the resistivity of scandium at 25° C.[1].

The temperature coefficient of resistivity decreases as the temperature is raised, the corresponding values being $3{\cdot}7 \times 10^{-3}$ at 100° C., $2{\cdot}1 \times 10^{-3}$ at 500° C., and $1{\cdot}3 \times 10^{-3}$ Ω/Ω −° C. at 900° C.

An attempt was made to determine the thermal conductivity of the wire using Kannaluik's method, but in practice the contact wires were not sufficiently massive to keep the temperature of the ends of the specimen down to ambient temperature as required by Kannaluik. An estimate can be made of the thermal conductivity by using the Weidemann–Franz relationship, since it is probable that the Lorenz ratio for scandium is similar to that of the early members of the rare earth series, that is, around $2{\cdot}7 \times 10^{-8}$ c.g.s. units. On this basis, the thermal conductivity of scandium would be 0·027 cal. cm./cm.^{2} sec. deg. C., at room temperature.

In the X-ray diffraction studies, using a 19-cm. high-temperature powder camera, scandium was examined at temperatures up to 850° C. The filings had been sealed in a thin-walled silica tube under vacuum but even so at a temperature of 750° C. the lines of scandium oxide appeared on the film. No attempt was made to take photographs above 850° C. because of the limitations of furnace power and the rapidly increasing strength of the oxide lines.

The structure remained hexagonal close-packed throughout the temperature range employed. The values of the lattice parameters and of the axial ratio are shown in Fig. 2; the behaviour is very similar to that of many of the rare earths[2], the c parameter increasing more rapidly than the a parameter at low temperatures, while at high temperatures the rate of increase of the parameters is comparable so that the axial ratio becomes approximately constant. A least-squares fitting of the experimental points gives the following values for the instantaneous coefficients of thermal expansion:

$$a = (5{\cdot}6_8 + 1{\cdot}3_7 t).10^{-8}/^\circ\,\mathrm{C}.$$

$$c = (12{\cdot}7_5 + 0{\cdot}5_7 t).10^{-6}/^\circ\,\mathrm{C}.$$

where t is the temperature (deg. C.). Thus the values for temperatures of 100° C., 500° C., and 800° C. are 7·1, 12·5 and $16{\cdot}6 \times 10^{-6}$/deg. C., for α_a and 13·3, 15·6 and $17{\cdot}3 \times 10^{-6}$/deg. C. for α_c.

Control of Irradiation Embrittlement in Molybdenum

IRON, steel, and other body-centred cubic metals show an increase in ductile-brittle transition temperature as a result of neutron irradiation. In an attempt to elucidate the mechanism of this embrittlement for *EN*2 steel, Hull and Mogford[1] studied the effect of neutron irradiation on the parameters σ_i and k_y in the Petch relation:

$$\sigma_y = \sigma_i + k_y d^{-1/2} \qquad (1)$$

where σ_y is the yield stress and $2d$ the grain diameter. They found that σ_i, the lattice friction stress, increased, but k_y, which is a measure of the strength of dislocation locking, remained constant. They interpreted this to mean that the embrittlement was caused by point defects or groups of defects which impeded the movement of slip dislocations in their glide planes. This simple phenomenological description of irradiation embrittlement enables changes in ductile-brittle transition temperature caused by irradiation to be predicted from Cottrell's brittle fracture criterion[2]:

$$(\sigma_i d^{1/2} + k_y)k_y \geqslant \beta\mu\gamma \qquad (2)$$

once σ_i has been measured as a function of integrated neutron flux.

Johnson[3] has applied a similar method to that of Hull and Mogford in studying the irradiation embrittlement of molybdenum. His results showed that the embrittlement mechanism in molybdenum is more complex than for *EN*2 steel, and in interpreting his results Johnson suggested that in pure metals the point defects created during irradiation cause dislocation climb. It follows that the effect of irradiation on the mechanical properties of a pure metal such as molybdenum should depend on the density and distribution of dislocations in the metal before irradiation.

In an initial attempt to observe this expected dependence of irradiation embrittlement on dislocation density and distribution, experiments have been performed on molybdenum with two different types of dislocation structures. The first type of material was heavily cold-worked by swaging and the second type heavily cold-worked and then stress-relieved at 1,000° C. for ½ hr. to give a fine sub-structure. The starting material in each case was Murex sintered molybdenum containing nominally 50–100 p.p.m. carbon, 50 p.p.m. iron, 20 p.p.m. oxygen, 10 p.p.m. hydrogen, and 5 p.p.m. nitrogen. Both materials were machined into Hounsfield type tensile specimens and four batches of ten specimens of each were irradiated in *Bepo* for 3, 6, 9 and 12 months respectively at a temperature of 40–50° C. The corresponding integrated epithermal neutron fluxes were about 1, 2, 3 and 4×10^{19} n.v.t. The ductile-brittle transition temperatures of the unirradiated materials and of each of these eight batches of irradiated specimens were measured using a modified Hounsfield tensometer operating at a strain rate of $0{\cdot}88 \times 10^{-4}$ sec.$^{-1}$.

The ductile-brittle transition temperature of each batch was taken to be the highest temperature at which no appreciable plastic deformation occurred before fracture. On this criterion the transition temperature for both types of materials was $+ 120 \pm 10$° C. both before and after irradiation. Moreover, irradiation did not influence the shape of the load-elongation curve at any temperature. The transition temperature of recrystallized specimens of the same batch of molybdenum was $- 60 \pm 10$° C.

These results indicate that at least some measure of control of the irradiation embrittlement of body-centred cubic transition metals can be achieved by using materials with controlled dislocation structures. A fuller account and discussion of these results is to be published elsewhere.

This work was initiated under a U.S. Navy Department Contract and in its later stages was financed by the U.K. Atomic Energy Authority and Central Electricity Generating Board. It was carried out under the general direction of Prof. J. G. Ball.

CHEMICAL ENGINEERING

Evidence of Phase Changes in Zirconia from Thermal Etching

ZIRCONIA is known to exist in at least two crystallographic forms. The stable form at room temperatures is monoclinic[1], but this transforms to a tetragonal lattice at some temperature between 950° and 1,250° C. (ref. 2), depending on the purity of the oxide. Cohn[3] has claimed a third form, hexagonal, obtained by heating for prolonged periods above 1,900° C. in a solar furnace. Up to the present, this has not been confirmed, but we believe we may have obtained evidence of three forms of zirconia.

We have recently completed the design, construction and testing of a carbon arc image furnace (unpublished work), which was used to investigate the melting of zirconia. Specimens were prepared from two batches of powder: one (prepared from Travancore beach deposits), with a range of particle size of 30–500μ, was claimed to be of very high purity except for 5·06 wt. per cent of hafnium oxide; the other (presented by Magnesium Elektron, Ltd.), with a range of particle-size of approximately 2–10μ, was analysed by the suppliers as containing, in terms of p.p.m. of zirconium content: 30 hafnium, < 20 manganese, 40 chromium, 460 iron, 153 silicon, < 30 vanadium, 42 nickel and 115 aluminium. The powders were compressed, without any lubricants or binders, into thin disks under a pressure of approximately 40 tons/sq. in., and melted in air in the arc image furnace. Melting took approximately 2 min., after which the specimens were allowed to cool. When the melted surfaces were examined under the microscope, grooves were seen at grain boundaries and some areas also showed surface striations the direction of which changed from one grain to another. These phenomena constitute thermal etching.

The conditions for and possible mechanisms of the formation of boundary grooves and surface striations have been discussed by Chalmers *et al.*[4]. It is concluded that a reduction in free energy of a strain-free lattice takes place by the reduction of surface and grain-boundary free energies. For ionic crystals, it has been shown by Lennard-Jones and Taylor[5] that the surface free energy depends upon the crystallographic orientation of the surface. Experimental evidence of this was obtained when single-crystal spheres of rock salt[6] and of alumina[7] were heated: crystal faces were developed and the spheres changed eventually to polyhedra.

Thermal etching, particularly of the grain-boundary grooves as opposed to the surface striations, has been used to determine the austenitic grain size of iron and steels[8]. This is possible because the grooves formed around the grains of the high-temperature phase persist after a phase change to the low-temperature form has occurred, so that two sets of grain boundary grooves are finally observed. The boundary grooves move as grain-growth occurs, without, in general, leaving traces of their former positions.

Although a number of investigations of the thermal etching of metals have been reported, little attention appears to have been given to the thermal etching of ionic crystals in general[9]. The results obtained with zirconia suggest that the method may be of general use as a rapid means of determining whether phase changes have occurred at high temperatures when the high-temperature phase cannot be retained by fast cooling. The accompanying photographs show part of the melted surface of zirconium with high hafnium oxide content (Fig. 1) and with low hafnium content (Fig. 2). Examination of Fig. 1 shows faint broad grooves delineating a small pentagonal region near the centre. A second set of narrower grooves meet in the centre of this region and in turn cross a third set of broad grooves which appear to be distinct from the first set. Some surface striations are also visible. In Fig. 2 grooves outline a large, roughly equi-axial, region in the centre. Within this region two sets of apparently distinct grooves meet, and a third groove, apparently distinct from both sets, crosses them. It is suggested that these three sets of grooves indicate that zirconia passes through three crystallographic forms in cooling from its melting point to room temperature. However, the possibility cannot be dismissed that some of the grain boundary grooves may be growth scars rather than 'phase scars'. But, the total heating and cooling time was relatively short—probably less than 5 min. for the cycle 1,000° C. to melting point ($\sim 2,700$° C.) to 1,000° C., whereas in the only instance where Chalmers *et al.* reported finding a growth scar (on a thermally etched silver specimen) the time at high temperature was 15 hr. By virtue of Cohn's claim and what appears to be a feasible interpretation of the evidence presented here, the behaviour of zirconia at high temperatures would seem worthy of further attention. It is, perhaps, significant that both Cohn and ourselves have used an image furnace in their preparation of the material. This method of heating[10] avoids contamination from furnace materials which may otherwise occur at high temperatures. Work on this topic is proceeding.

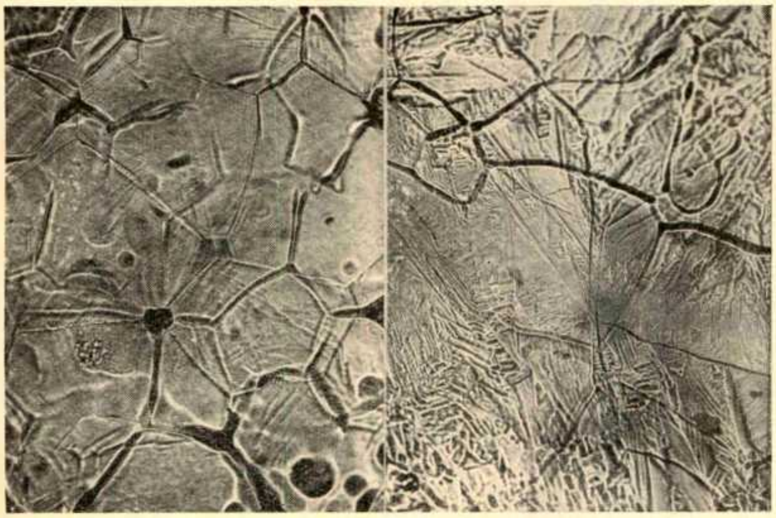

Fig. 1. High-hafnia zirconia. Fig. 2. Low-hafnia zirconia. (× 300)

We thank Prof. Frank Morton for the facilities he has made

available, our colleagues H. Holness[11] and R. W. Adams for the sample of Travancore zirconia and the determination of its hafnium oxide content, and Dr. S. J. Fletcher, of Magnesium Elektron, Ltd., for the sample of low-hafnia zirconia. One of us (G. W.) is indebted to the Department of Scientific and Industrial Research for a maintenance grant.

CHEMISTRY

Gas Chromatographic Separation of Low-boiling Hydrocarbons using Active Alumina as Support for the Liquid Phase

SYSTEMATIC research into the behaviour of aluminium oxide as a support in gas chromatographic columns has, to our knowledge, been carried out by Hrapia[1] and Scott[2]. Hrapia was concerned principally with retention volumes and column performance and Scott with the deactivation of alumina with water.

We have found, at column temperatures between 0° and 70° C., that non-volatile liquids such as squalane, triethylene glycol and ββ′-oxydipropionitrile are suitable impregnating agents for alumina supports. The liquid phase is added to the support (γ-$Al(OH)_3$ containing 0·22 per cent by weight Na_2O, grain size 0·1–0·15 mm., calcined for 9 hr. at 400° C.) in dilution with a suitable volatile solvent (for squalane, petroleum ether, 40–70° C.; for polar liquids, methylene chloride) which is evaporated off prior to drying. During this final drying operation (5 hr. at 70° C.) alumina samples treated with polar liquids undergo losses of weight proportional to the quantity of liquid phase added; we can only explain these losses by assuming a release of chemically bound water from the surface of the alumina, suggesting the formation of surface compounds with the support. Aluminas impregnated with squalane show slight hygroscopicity even under drying conditions (compare Fig. 1).

Table 1

Liquid phase in alumina + liquid phase (per cent by weight)	HETP (mm.)		
	Squalane	ββ′-Oxydipropionitrile	Triethylene glycol
5	0·55	0·56	0·63
10	0·69	0·55	0·51
15	1·9	0·62	0·64
20–25	Column performance too low for the separation of low-boiling hydrocarbons		

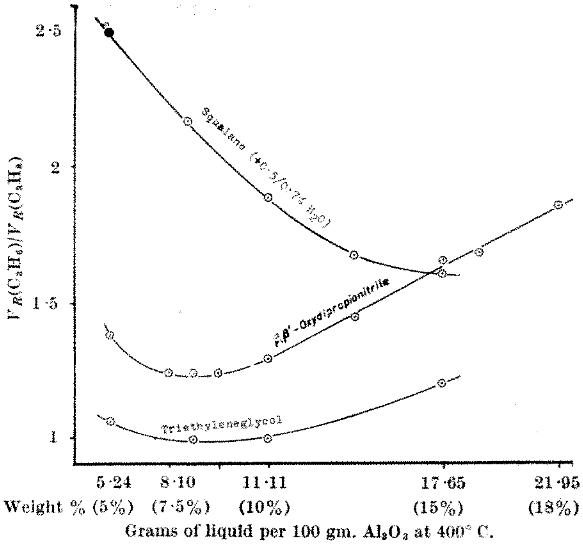

Fig. 1. Polarity charge with addition of liquid phase. V_R measured from air peak

It has been our experience that performances obtained with column packings having alumina as support are superior to those obtained with columns having an inactive support. The HETP values (height of equivalent theoretical plates) in Table 1 were obtained for packings of alumina + liquid phase

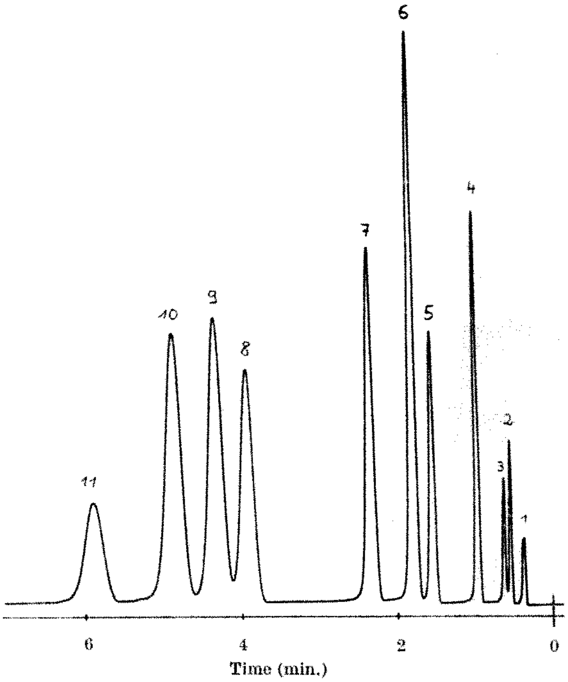

Fig. 2. Separation of C_1—C_4 hydrocarbons. (1) Air–methane; (2) ethane; (3) ethene; (4) propane; (5) propene; (6) *iso*-butane; (7) *n*-butane; (8) butene-1; (9) *iso*-butene; (10) *trans*-butene-2; (11) *cis*-butene-2

Sample size: 0·05 ml. (syringe). Column packing: 18 per cent by weight (= 20·95 gm. per 100 gm. Al_2O_3) of ββ′-oxydipropionitrile on 100–150 mesh Al_2O_3, calcined for 9 hr. at 400° C. Column dimensions: Copper tube, length 2 metres, inner diameter 4 mm. Column temperature: 0° C. Carrier gas: Hydrogen, inlet–outlet pressure ratio 2·66, inlet pressure 24·3 lb./sq. in. gauge, outlet flow-rate 70 ml./min. Thermal conductivity cell: heating current, 400 m.amp.; cell temperature, 0° C.

using *n*-butane as sample and hydrogen as carrier gas (outlet flow-rate 50–70 ml./min.).

Observations of the changes in retention volumes with change in the amount of liquid phase added show that retention volumes decrease continuously with increasing amounts of liquid phase (compared with Hrapia[1]).

Observations of the changes in polarity with change in the amount of liquid phase added are given in Fig. 1 in terms of the ratios of the retention volumes for propene and propane. With squalane the polarity of the alumina – liquid phase system decreases steadily with increasing amounts of liquid, whereas for polar liquids the polarity passes through a minimum. This latter observation indicates that to a certain extent the polarities of carrier and impregnating material compensate each other. The increase in polarity observed when adding polar liquids in amounts beyond those required for compensation is to be attributed mainly to the polarity of the surplus liquid. Mixed phases consisting of triethylene glycol and ββ′-oxydipropionitrile show polarities corresponding to the weight proportions of the individual compounds in the finished mixture.

The optimum conditions for gas chromatographic analysis, namely, short duration, column of low HETP, and polarity adequate for complete separation of sample components, are attained when all these considerations are taken into account. If the separation of air from methane is not required, the results tabulated with Fig. 2 are recommended for the analysis of C_1 to C_4 hydrocarbons (possibly including C_5). Under the same conditions, mixtures containing hydrocarbons up to C_7 have been separated with success. The reproducibility of the measurements is satisfactory. Further results and details will be published elsewhere.

Thanks are due to Dr. P. Vogt, c/o Gebrüder Giulini, GmbH, Ludwigshafen/Rhein (Germany), for providing the alumina supplies.

Gas Chromatographic Analysis of Permanent Gases using Standard Ionization Detector Equipment

Although the most common high-sensitivity detectors now in use for gas chromatography consist of either the flame[1] or the argon ionization device[2], such instruments cannot be used for the analysis of permanent gases when operated in the prescribed fashion. Thus in the argon chamber, the relatively low excitation potential of 11·6 eV. for metastable argon atoms is insufficient to ionize permanent gases which, unlike most organic compounds, have ionization potentials above this level. When we wished to employ gas chromatography for the analysis of gases extracted from the blood of man, it was decided to adapt existing equipment with as little alteration as possible. This was done by substituting ordinary commercial helium for argon as the carrier gas. The ionization chamber was a standard 1 cm. × 1 cm. microdetector which contained a 100-mc. tritium source.

Table 1. DETECTION OF PERMANENT GASES USING A STANDARD IONIZATION DETECTOR AND HELIUM AS A CARRIER GAS

Gas	Minimum sensitivity μl./sec.	Minimum sensitivity gm./sec.	Minimum sensitivity mole/sec.	Maximum linear range mole/sec.
Oxygen	0·015	2×10^{-8}	6×10^{-10}	$1{\cdot}6 \times 10^{-8}$
Nitrogen	0·035	4×10^{-8}	$1{\cdot}4 \times 10^{-9}$	$4{\cdot}2 \times 10^{-8}$
Hydrogen	0·040	$3{\cdot}6 \times 10^{-9}$	$1{\cdot}8 \times 10^{-9}$	$1{\cdot}8 \times 10^{-7}$
Nitric oxide	0·025	5×10^{-8}	1×10^{-9}	$2{\cdot}5 \times 10^{-8}$
Carbon monoxide	0·10	1×10^{-7}	4×10^{-9}	$6{\cdot}4 \times 10^{-8}$
Carbon dioxide	0·40	8×10^{-7}	2×10^{-8}	$1{\cdot}2 \times 10^{-7}$
Methane	0·10	7×10^{-8}	4×10^{-9}	$7{\cdot}2 \times 10^{-8}$
Ethylene	0·035	4×10^{-8}	$1{\cdot}5 \times 10^{-9}$	$4{\cdot}2 \times 10^{-8}$

Optimum operating conditions were obtained by selecting an applied potential which produced a standing current of 1×10^{-8} amp. at room temperature; usually 500 V. was sufficient. Contamination of the helium carrier stream by samples of permanent gases resulted in a decrease in standing current. The extent of this effect was taken as a measure of the quantity of gas being analysed. Although higher base currents gave an increase in sensitivity with a particular cell geometry, there was concomitant increase in the noise-level. Table 1 shows the minimum amount of the various gases which were detected under the conditions of the experiment. The detector was operated at 500 V. and the standing current was $0{\cdot}88 \times 10^{-8}$ amp. at 27° C. The noise-level was 5×10^{-11} amp.

The range of linearity for each gas is also listed in Table 1. By plotting a typical calibration curve as depicted for oxygen in Fig. 1, quantitative results can be extended beyond the linear range by at least a factor of five. Due to the mechanics of the detection system, the plot of decrease of current versus quantity of permanent gas passing through the detector tends to give a plateau at a minimum current-level. Although this range may differ somewhat for different gases and detectors of different design, the initial slope describing linear range is similar in all instances.

It should be noted that the ionization phenomena in operation in this application are different from those which would be expected if helium of extreme purity was used as the carrier gas[3]. Since increments in current were not noted, it was presumed that a reaction that would involve the contaminant gases and metastable helium atoms did not occur. At an applied potential of 500 V. to the detector, it is probable that the decreases in current which were

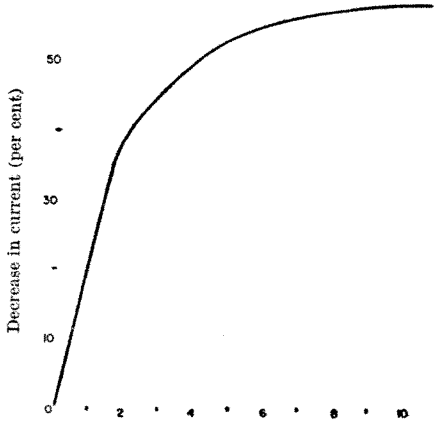

Fig. 1. Calibration curve for oxygen

observed were due to quenching of secondary electrons by molecules of the gas sample. The mode of operation of the detector also differs from that described by Willis[4], where the number of metastable argon atoms in the field were decreased by contaminating the argon carrier gas with ethylene. An electron mobility technique[5] in which a simple pulse generator is employed should offer considerable promise where additional sensitivity is required for the analysis of permanent gases. However, the sensitivity of the present method provides a very convenient compromise between this and conventional techniques where thermal conductivity detectors are used.

This investigation was supported by grants from the National Heart Institute of the National Institutes of Health, the National Dairy Council and the Nutrition Foundation.

α-Configuration of Fibrous Proteins

IT is now generally accepted that the polypeptide chain configuration in the group of fibrous proteins designated *k-m-e-f* by Astbury[1], which give the characteristic α X-ray diagram, is closely related to the α-helix described by Pauling, Corey and Branson[2]. In its simplest form, however, the α-helix does not account for the simultaneous appearance of the 5·2 and 1·5 Å. meridional arcs which are the diagnostic feature of the *k-m-e-f* group. Pauling and Corey[3] and Crick[4] suggested independently that these arcs might result from a systematic distortion of the α-helix in which the helix axis itself followed a helical path of large pitch. Detailed calculations by Crick[5] and Lang[6] showed that a group of three such helices twisted about a common axis to form a rope gives a satisfactory agreement with the observed diffraction pattern in the 1·5 and 5·0 Å. regions of the meridian.

We have recently investigated the diffraction pattern of the 3-strand rope in somewhat more detail using an optical diffractometer. While confirming the deductions of Crick and Lang, we find that the remainder of the meridional diffraction does not agree particularly well with the very wide-angle diffraction pattern that we have obtained from certain members of the *k-m-e-f* group. In Fig. 1 the optical transform of the 3-strand rope (*a*) is compared with the patterns obtained from α-keratin (*b*) and dried muscle (*c*). We have therefore explored the alternative possibility that in these proteins the α-helices, instead of being uniformly distorted, are composed of short straight segments with any distortion required for efficient packing being concentrated at a particular residue or residues and resulting in small but abrupt changes in the direction of the helix axis at these points. From the arguments put forward by Crick concerning the packing of helical polypeptide chains, groups of 2, 3 or more chains having the form envisaged above might be expected to form segmented ropes of similar average pitch to the uniformly distorted 3-strand rope.

The diffraction pattern of a segmented rope cannot be investigated without specifying the sequence of segment lengths and inclinations, but the general character of the transform is shown in Fig. 1*d*, which was obtained by an intensity addition of the diffraction from a number of segments 27 Å. in length inclined at a range of angles between 0 and 20° to the fibre axis. The maximum segment length is determined by the gradual divergence of the inclined helix axes and the accompanying departure from the idealized 'knob/hole' packing arrangement envisaged by Crick. A study of atomic models indicates that this length is probably in the region of 20–30 Å. The intensification of the eighth order meridional reflexion (Bragg spacing 24·6 Å.) that we have observed in the X-ray diagram of α-keratins after treatment with many heavy atom stains, for example,

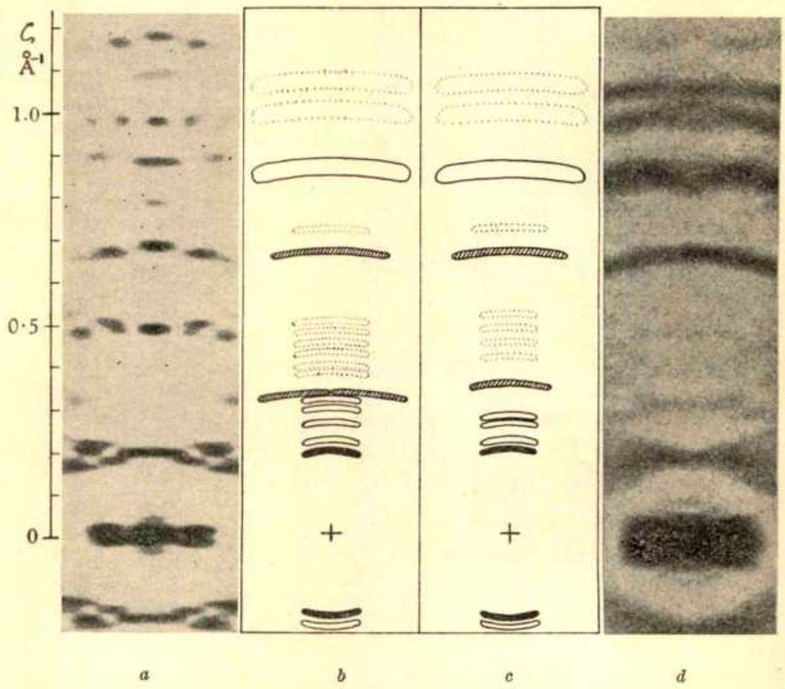

Fig. 1. *a*, The optical transform of the repeating unit of the three-strand rope described by Crick (ref. 5). The major helix is left-handed, the minor helix is right-handed and a β-carbon atom is included in the *L*-configuration about the α-carbon atom. *b*, The spacings and approximate relative intensities in the observed X-ray diffraction pattern from porcupine quill tip. Very weak reflexions are enclosed by a dotted line, weak reflexions by a full line, medium reflexions are shaded and strong reflexions shown solid. *c*, The observed X-ray diffraction pattern from dried toad sartorius muscle. *d*, The simulated optical transform from a segmented cable. The co-ordinate of the '5·2 Å.' arc is 0·19 Å.$^{-1}$ and that of the '1·5 Å.' arc is 0·67 Å.$^{-1}$

silver, mercury, copper and lead, may be associated with this length.

BIOCHEMISTRY

Nature of Thyroxine-binding Globulin in Human Serum

The term thyroxine-binding globulin is often used to denote a serum protein fraction with a mobility intermediate between those of α_1- and α_2-globulins in paper or moving-boundary electrophoresis in veronal buffer, pH 8·6, ionic strength 0·05–0·10 (ref. 1). However, with the introduction of supporting media such as agar and starch gels and the use of different buffers, ionic strength or pH for paper electrophoresis, binding of thyroid hormones has also been detected in the 'prealbumin' zone[2]. Although the proteins of the 'prealbumin' zone obtained under different conditions are not likely to be identical, a strong thyroxine-binding property was detected in human serum prealbumin rich in tryptophan[3], as obtained from Prof. Schultze[4]. From chemical and immunological observations I concluded that the tryptophan-rich prealbumin, present as a complex in the α-globulin fraction, might be responsible for much of thyroxine-binding in human serum[5]. Since then, an α-globulin-type of thyroxine-binding protein has been obtained in this laboratory (unpublished results); the nature of this protein does not support the hypothesis that the tryptophan-rich prealbumin is involved in binding thyroxine. One possible explanation for this discrepancy is that Schultze's prealbumin preparation contained traces (1–2 per cent) of thyroxine-binding globulin which were responsible for the production of antibodies to it present in antisera against this prealbumin. In fact, multiple precipitation lines were observed in immunological studies using rabbit anti-human prealbumin serum[5]. The experiments to be described support this explanation and throw further light on the nature of the thyroxine-binding globulin in human serum.

A protein with strong thyroxine-binding properties was isolated (or prepared as an enriched fraction) from whole human serum, human cerebrospinal fluid and Cohn fractions IV-4 and IV-9 by a method which will be described elsewhere. The same major component was obtained from all the starting materials and will be referred to as thyroxine-binding globulin. A 1 per cent solution of this thyroxine-binding protein in 0·15 M sodium chloride was generally used for immunological studies. In Fig. 1 is shown a typical result observed when preparations of thyroxine-binding globulin were compared with tryptophan-rich prealbumin using rabbit anti-prealbumin serum (also obtained from Prof. Schultze) using Ouchterlony's double-diffusion technique[6]. Two major precipitation lines were seen for the tryptophan-rich prealbumin and Cohn fraction IV-9. A third line was also observed, if human serum was tested (not shown in Fig. 1). Only one line could, however, be detected in preparations of thyroxine-binding globulin, irrespective of the source. This precipitation line was continuous for the different preparations and with one of the lines obtained with tryptophan-rich prealbumin, Cohn fraction IV-9, and with whole serum, Cohn fraction IV-4 and cerebrospinal fluid, which were tested separately. This indicated that the thyroxine-binding globulin is an antigen common to all the preparations tested.

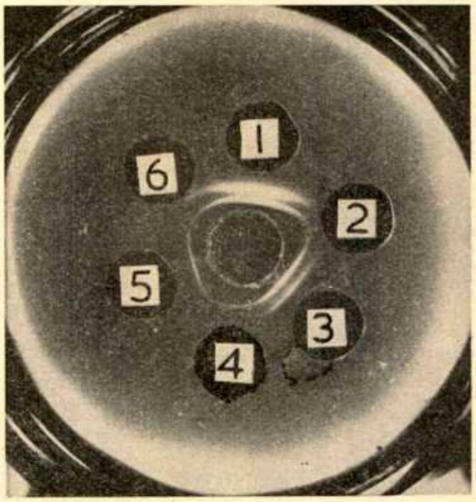

Fig. 1. Immunological interaction, using Ouchterlony's double-diffusion technique in agar gel, between rabbit antiserum against human serum tryptophan-rich prealbumin (ref. 4) (central well) and (1) tryptophan-rich prealbumin, (2) thyroxine-binding globulin prepared from unfractionated human serum, (3) Cohn fraction IV-9, (4) and (5) two different preparations of thyroxine-binding globulin made from Cohn fraction IV-9, and (6) thyroxine-binding globulin prepared from human cerebrospinal fluid;

Immuno-diffusion studies by the method of Allison and Humphrey[7] helped in deciding whether the tryptophan-rich prealbumin itself was not the common antigenic component. In this method the antigen and antibody troughs are placed at right angles, as shown in Fig. 2, and the angle θ formed between the precipitation line and the antigen trough is measured. The diffusion coefficients and consequently the relative molecular weights of the antigens were estimated from the equation, $\tan\theta = (D_g/D_b)^{1/2}$, where D_g and D_b are diffusion coefficients of the antigen and antibody respectively. Two major precipitation lines were again observed with the prealbumin (Fig. 2a), and the molecular weights of the two antigens were estimated to be about 60–65,000 for component 1 and 40–45,000 for component 2. Component 1 therefore corresponds to tryptophan-rich prealbumin itself, which has a molecular weight of 61,000 (ref. 4). With a preparation of thyroxine-binding globulin (Fig. 2b), only one line was observed, corresponding to an antigen of molecular weight of 40–45,000. This is the common antigen present in all the samples shown in Fig. 1; its lower molecular weight is compatible with the precipitation occurring nearest to the antibody trough in Fig. 1. It is therefore concluded that Schultze's tryptophan-rich prealbumin is not alone involved (either free or

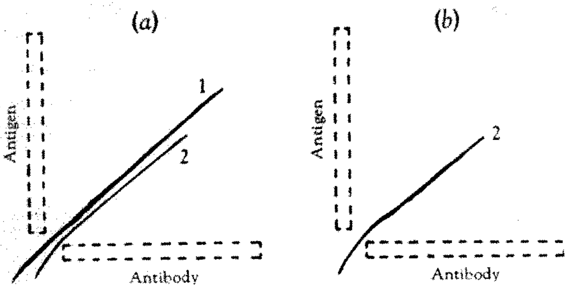

Fig. 2. Immunological reaction obtained using the technique of placing antigen and antibody troughs at right-angles, thus permitting an estimation of diffusion coefficients of antigens (ref. 7). The antibody trough contained rabbit antiserum against human serum tryptophan-rich prealbumin. (a) The antigen trough contained a 1·5 per cent solution of tryptophan-rich prealbumin. (b) The antigen was thyroxine-binding globulin obtained from Cohn fraction IV-9

complexed) in the transport of thyroid hormones in human blood, contrary to a previous suggestion[5], but that a distinct thyroxine-binding protein of a smaller size is responsible. The above immunological work also shows that the samples of tryptophan-rich prealbumin studied in this laboratory contained traces of thyroxine-binding globulin, estimated to be about 1–3 per cent of the protein from its unusually low binding capacity in the prealbumin samples.

Physical and chemical measurements made on preparations of thyroxine-binding protein have all confirmed the above conclusions. Zone electrophoresis on paper, cellulose acetate, agar gel and starch gel in various buffers, immunoelectrophoresis, sedimentation in the ultracentrifuge and measurement of tryptophan and sugar content reveal the differences between thyroxine-binding globulin and tryptophan-rich prealbumin. On the other hand, thyroxine-binding globulin resembles the α_1-glycoproteins of small molecular weight of Schultze and Schmid and their collaborators[8], although it may not be the same as the protein described by these workers. Some of the similarities and differences between thyroxine-binding globulin and other serum proteins, which will be described elsewhere, are summarized in Table 1.

Table 1. COMPARISON OF SOME PROPERTIES OF THYROXINE-BINDING GLOBULIN WITH THOSE OF SOME ISOLATED HUMAN SERUM PROTEINS

Sample	Electrophoretic mobility (-10^{-5} cm.^{2} V.$^{-1}$ sec.$^{-1}$)	Sedimentation constant ($S_{20,w}$)	Chemical analysis
TBG (unfractionated serum)	4·7 (*p*H 8·6) 1·7 (*p*H 4·5)	3·3	
TBG (isolated)	4·9 (*p*H 8·6) 1·8 (*p*H 4·5)	3·5	High sugar, low lipid, low tryptophan
α-Glycoprotein (ref. 8)	5·0 (*p*H 8·6)	2·9, 3·1, 3·5	High sugar
Prealbumin (ref. 4)	9·0 (*p*H 8·6)	4·2	High tryptophan

It is important to note that the sedimentation constant and electrophoretic mobilities of isolated thyroxine-binding globulin compare well with the values derived by Robbins, Petermann and Rall[9] for the major component in unfractionated human serum to which thyroid hormones are bound. The evidence presented here does not attempt to explain the diversity of thyroxine-binding protein zones when various conditions of electrophoresis of human serum are used[2]. It is concluded from these observations that the principal thyroxine-binding protein in human serum is an α_1-glycoprotein of small molecular weight; this necessitates a revision of the earlier suggestion that the tryptophan-rich prealbumin was alone involved in the transport of thyroid hormones in human blood[5].

I thank Dr. R. B. Pennell for Cohn fractions of human plasma; Prof. H. E. Schultze for human serum prealbumin rich in tryptophan, and immune rabbit serum; Dr. Marshall for human cerebrospinal fluid; Dr. K. Schmid for α_1-acid glycoprotein; Dr. P. Charlwood for ultra-centrifugal analysis and, finally, Drs. W. Gratzer and D. Tee for invaluable help and advice in zone electrophoresis, immunoelectrophoresis and tryptophan determinations.

Influence of the Charge on a Serum Protein Molecule and its Ability to stimulate or inhibit the Phagocytosis of Bacteria by Leucocytes

THE present work was undertaken to investigate the effect of various human serum proteins upon the phagocytosis of *Staphylococci* by human leucocytes, and in particular to show the effect of modifying the net charge on the serum protein molecule upon the ability of the protein to stimulate or inhibit phagocytosis.

A modification of the slide-cell technique of Wright[1] has been used to assess the phagocytic ability of human leucocytes towards bacteria.

Human defibrinated blood from healthy Group O donors has been used. Part of any given sample of blood was used in its defibrinated condition without further treatment, but a part was centrifuged at high speed, and samples of serum and packed erythrocytes pipetted off under aseptic conditions and then re-mixed to give leucocyte-free blood of the same hæmatocrit as the original. The total leucocyte count of this latter sample was less than 3 per cent of the original count.

The slide-cells were constructed from two microscope slides separated by five strips of waxed paper, prepared under sterile conditions, in such a way that four shallow compartments were produced as shown in Fig. 1.

0·1 ml. of a 1 in 200,000 normal saline dilution of a peptone–water culture of *Staphylococcus aureus* (Wellcome Collection, No. *CN* 3638) was mixed with

0·1 ml. of an isotonic solution in saline of the protein to be tested, plus 0·8 ml. of the blood or leucocyte-free blood. The compartments of the slide-cell were filled as indicated and sealed around with melted paraffin wax, incubated at 37° C. for 15–20 hr., and then the number of bacterial colonies seen in ten low-power microscope fields noted for each compartment.

Human serum from healthy Group O donors was used for the preparation of the serum protein fractions. The serum was brought to 55 per cent saturation at 4° C. with ammonium sulphate (Analar grade), centrifuged at this temperature, and the precipitate re-dissolved in half the original volume of distilled water. Both this solution and the supernatant from the ammonium sulphate fractionation were then exhaustively dialysed against distilled water and afterwards lyophilized for storage.

The two serum protein fractions obtained were then used to prepare samples of both the acetylated and the methyl esterified derivatives, using the methods of Fraenkel-Conrat[2]. The methyl esterification was performed by treating a methanol solution, so far as it was soluble, of the protein at −15° C. with a small quantity of concentrated hydrochloric acid. Having kept the reaction mixture in the deep freeze for 48 hr., it was exhaustively dialysed against distilled water and lyophilized.

Electrophoretic separation of the proteins was done in duplicate on Whatman 3*MM* paper in barbitone buffer *p*H 8·6, ionic strength 0·05. After 18 hr. separation at 7 V./cm., one strip from each pair was dried and stained with bromophenol blue. The electropherograms were scanned in a slightly modified EEL scanner. The unstained strips were then eluted in order to measure ability of the protein fractions to stimulate or inhibit phagocytosis. The areas eluted are represented by the shaded areas in the electropherograms in Fig. 2. The eluant used was the same buffer as was used for the electrophoresis, and the eluted proteins were dialysed free of barbitone through 'Cellophane' tubing against normal saline containing 0·001 *M* phosphate buffer *p*H 7·2. The proteins were then concentrated by ultrafiltration through 'Cellophane' tubing to a final concentration of 5 per cent w/v, filtered free of bacteria, and used in the test of phagocytosis.

From Fig. 1 it is seen that the difference between the number of bacterial colonies which appear in a compartment containing leucocytes and in one which is devoid of leucocytes represents the antibacterial capacity of the leucocytes under the conditions in question. For simplicity this will be referred to as the phagocytic ability.

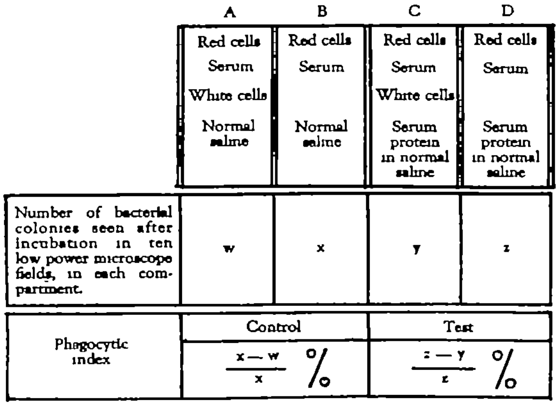

Fig. 1. Construction of slide-cells and calculation of results

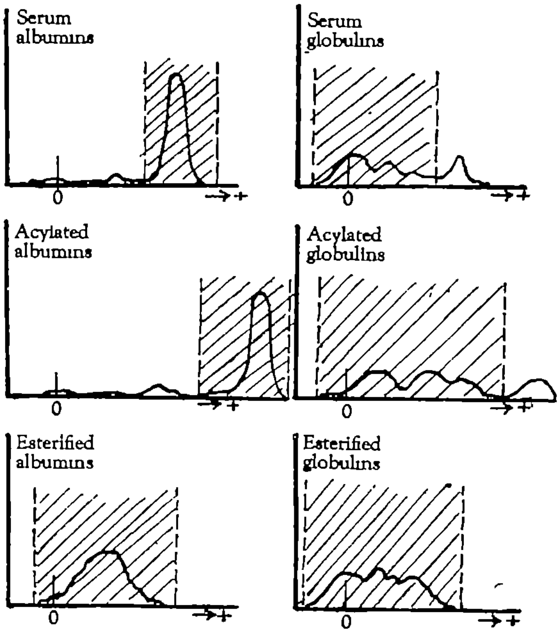

Fig. 2. Electropherograms of proteins, 0 being the point of application

Fig. 2 and Table 1 summarize the results obtained. In confirmation of the work of Tullis[3], the albumin fraction of the serum inhibits phagocytosis, and there is a significant stimulation with the globulins. Acetylation of a serum protein increases the negative charge on the molecule and either increases the inhibitory properties of albumins or decreases the stimulatory property of globulins. On the other hand, the esterification has been shown by electrophoresis to decrease the net negative charge on the serum protein molecule and increase the stimulatory effects of the globulins; but for some unexplained reason has had little effect on the properties of albumins in phagocytosis.

Table 1. PHAGOCYTIC INDICES IN A FINAL CONCENTRATION OF THE ADDED PROTEIN OF 1 PER CENT W/V

Substance	Phagocytic index	
	Mean	Standard error
Normal saline control	61	± 3·1
Serum albumins	43	± 2·7
Serum globulins	70	± 3·3
Acylated albumins	29	± 2·9
Acylated globulins	55	± 2·4
Esterified albumins	31	± 2·7
Esterified globulins	84	± 3·6

It would seem from these results that, for a given protein, the more negative its charge the more inhibitory it is towards phagocytosis, and conversely, the less the negative charge the more it will stimulate phagocytosis. In the case of the globulins, there seems to be the potentiality for either stimulation or inhibition of phagocytosis; yet the albumins seem to be capable only of inhibition. Clearly, therefore, there are other properties of a protein molecule besides its charge which determine its effect on phagocytosis.

I wish to thank Prof. G. A. H. Buttle for introducing me to the methods for measuring phagocytosis, and Dr. I. A. Hansen for suggesting the present investigation.

Synthesis of Biologically Active Cellulose Derivatives of Enymes

Modified celluloses have been combined chemically with a variety of enzymes, with retention of enzymatic activity but with interesting and useful modifications of some properties. Derivatives have been prepared with carboxymethylcellulose and diazobenzylcellulose.

All derivatives are covalently linked and are stable to water, salt solution, acid, and buffer, and all can be dried by lyophilization without loss in activity. Derivatives of diazobenzylcellulose are insoluble, whereas those of carboxymethylcellulose vary from insoluble to water soluble, depending upon the characteristics of the carboxymethylcellulose. Soluble derivatives possess activity comparable with or greater than that of the free enzyme, but the insoluble derivatives are considerably less active.

Coupling with carboxymethylcellulose was effected by a modification of the azide method of Michael and Evers[1]. The entire process was carried out at 0° in a centrifuge bottle. Carboxymethylcellulose azide was prepared by suspending 1 gm. of its hydrazide in 150 ml. of 2 per cent hydrochloric acid solution and slowly stirring in 9 ml. of 3 per cent sodium nitrate solution. After 20 min., insoluble carboxymethylcellulose azide was separated by centrifugation and washed with 150 ml. of dioxane and then with distilled water to neutrality. Soluble carboxymethylcellulose azide, in the supernatant liquid, was precipitated by adding methanol to a final volume of 62 per cent, separated, and then washed several times with phosphoric acid solution at *p*H 2 before a final wash with distilled water. The carboxymethylcellulose azides were then separately stirred with 250–450 mgm. enzyme in 100 ml. of 0·05 *M* phosphate buffer at *p*H 8·7 for 2 hr. The insoluble derivative was then adjusted to *p*H 4 with 0·1 *M* phosphoric acid, separated, washed twice with 150 ml. of *p*H 3 water and once with distilled water, and finally lyophilized. The soluble derivative was precipitated at *p*H 3·5 with methanol (13 per cent) at − 5°, washed once with dilute phosphoric acid at *p*H 2 and once with water, and then lyophilized.

Soluble derivatives were obtained from more highly substituted cellulose, whereas lower degrees of substitution yielded derivatives with varying solubility properties. For example, a cellulose with low substitution (carboxymethylcellulose azide was prepared from carboxymethylcellulose products with different carboxyl equivalents obtained from Hercules Powder Co., Wilmington, Delaware, and Brown Co., Berlin, New Hampshire) yielded only an insoluble derivative, while one with an intermediate degree of substitution yielded an enzyme derivative that was soluble at *p*H 7 but insoluble at *p*H 3. It is not possible to be specific in predicting the solubility of the derivatives because of such factors as the uniformity of substitution, the number of free carboxyl groups in the final product, and the condition of the cellulose fibre.

Table 1. Comparison of Protein coupled and Enzyme Activity demonstrated by Chymotrypsin Derivatives (Typical Results)

Substitution on cellulose	Low	High		
Solubility of derivative	Insoluble	Insoluble	Alkali-soluble	Soluble
Mgm. protein coupled*/gm. derivative	95	350	221	558
Mgm. enzyme equivalent†/gm. derivative	30	86	172	1,071

* The protein was determined by spectrophotometric analysis at 280 mμ on the solutions before and after coupling.

† The quantity of enzyme in the derivative was calculated by comparison with the activity of the free enzyme on acetyl tyrosine ethyl ester (ref. 2).

Because of variations in the amount of carboxyl substitution on the cellulose, the quantity of enzyme coupled varies. The greater the original degree of substitution the greater the enzymatic activity of the derivatives; surprisingly, the activities of the soluble derivatives are equal to or greater than the activity of the free enzyme (Table 1).

In general, the activity of the derivative is related to the degree of hydration of the product rather than to the amount of enzyme coupled. This has been shown by comparing two insoluble derivatives with equal amounts of protein substituted on the cellulose. A derivative which had a tendency to swell in solution was 2–3 times as active as a derivative that did not show this property.

Limited studies indicated that both insoluble and soluble carboxymethylcellulose derivatives of chymotrypsin are more stable to heat than free chymotrypsin, the insoluble derivative possessing the greatest stability. There appears to be no shift in the *p*H optimum. The insoluble derivatives of trypsin and chymotrypsin are more active on small substrates, for example, acetyl tyrosine ethyl ester[2], than on large substrates, for example, hæmoglobin[3], showing some spatial limitation. Furthermore, the trypsin inhibitor of blood fails to inhibit the insoluble trypsin derivative, which further suggests spatial interference.

The second type of derivative was not so successful as the first, but proved that the cellulose–enzyme union is not restricted to one type of linkage. Insoluble diazobenzylcellulose derivatives of ribonuclease and chymotrypsin were synthesized by the coupling procedure of Campbell *et al.*[4]: 1 gm. of enzyme in 100 ml. of 0·05 *M* borate buffer at *p*H 8·7 was treated with 1 gm. of diazotized *p*-aminobenzylcellulose at 0°. Analysis indicated that the ribonuclease derivative was as much as 23 mgm. per cent protein, and the chymotrypsin derivative 34 mgm. per cent protein. However, the activities determined spectrophotometrically for ribonuclease[5] and titrimetrically for chymotrypsin[2] correspond to only 0·6 mgm. per cent, and 1·3 mgm. per cent enzyme, respectively. More work on this series may improve the activity incorporated into the derivative.

The use of modified cellulose in the synthesis of enzymatic derivatives should be applicable to an extensive series of purified enzymes. Not only may a study of these derivatives reveal information on how insoluble enzymes function, but it may also reveal a very practical way to use certain enzymes. For example, the insoluble carboxymethylcellulose-trypsin derivative has been used in our laboratory to effect a controlled chymotrypsinogen-to-chymotrypsin conversion. After the conversion, the derivative was easily recovered, leaving no trypsin contamination of the chymotrypsin; and with proper precautions, the derivative was re-usable. Similar applications could be suggested for other enzymes.

Distribution of Coenzyme Q in Rat Liver Cell Fractions

COENZYME *Q* (Co*Q*), which is widely distributed in animal, plant and microbial sources, has been implicated in electron transport[1] and generally assumed to be associated with mitochondria. However, it has also been found in non-mitochondrial fractions of green leaves, although it appears to be concentrated in mitochondria[2]. A similar distribution has now been demonstrated in rat liver cell fractions.

Livers of stock colony rats were homogenized and fractionated by Schneider's method[3]. The following determinations were made: coenzyme *Q* by the decrease in absorption at 275 mμ on addition of sodium borohydride[4], succinic dehydrogenase by the reduction of dichlorophenol indophenol[5], $CoQH_2$ oxidation[6] (which is sensitive to antimycin and cyanide and therefore a measure of cytochrome oxidase), acid phosphatase[7] after pre-incubation for 1 hr. at 37° C., esterase activity with menadiol diacetate as substrate (Ramasarma, T., unpublished results), and protein by the biuret method[8].

Determinations of the distribution of coenzyme *Q* in rat liver cell fractions, giving a set of typical results of a number of experiments, are presented in Table 1. The mitochondrial fraction contained only 41 per cent of the total coenzyme *Q* and the rest of it was distributed in other fractions. The presence of coenzyme *Q* in all the fractions was confirmed by reverse phase paper chromatography. The large proportion of coenzyme *Q* present in the nuclear fraction (37·5 per cent) does not appear to be due to contamination of whole cells or mitochondria, since the acid phosphatase, $CoQH_2$ oxidation and esterase activities were low. But, since 30 per cent of the total succinic dehydrogenase was recovered in this fraction, the possibility of contamination by mitochondrial fragments cannot be excluded. The amount of coenzyme *Q* present in the fraction of sub-microscopic particles, the total as well as on the protein basis, was about one-third of that in the mitochondria, but the activities of succinic dehydrogenase and $CoQH_2$ oxidation in this fraction were several times lower in content and specific activity in comparison to mitochondria. Therefore the coenzyme *Q* in this fraction cannot be of mitochondrial origin, but appears to be partly constitutive and thus a wider role for coenzyme *Q* is suggestive. Whether the coenzyme *Q* present in sub-microscopic particles participates in the two oxidative enzyme systems—reduced diphosphopyridine nucleotide–cytochrome *c* reductase and the oxidation of *L*-gulono-γ-lactone—will be of interest, particularly in view of the observation of an involvement of a lipid co-factor in the latter system[9]. It is interesting to note that vitamin K, also a lipid-quinone, was found to be similarly distributed: nuclei 24 per cent, mitochondria 61 per cent, and sub-microscopic particles and supernatant 15 per cent, as tested by its biological activity[10].

Table 1. DISTRIBUTION OF COENZYME *Q* IN RAT LIVER CELL FRACTIONS

	Nuclei	Mito-chondria	Sub-microscopic particles	Super-natant
Coenzyme *Q* μmole/gm. protein	0·570	0 940	0 330	0 071
(per cent)	37 5	41	14 5	7
Succinate dehydrogenase activity	0·0095	0·0240	0·0040	0·0030
(per cent)	30	50	6	14
$CoQH_2$ oxidation activity	0·0007	0·0095	0 0008	0 0004
(per cent)	9	78	5	8
Acid phosphatase activity	0·0040	0·0340	0 0150	0·0035
(per cent)	10	56	21	13
Esterase activity	0 005	0 285	0·925	0·240
(per cent)	4	17	46	33
Protein (gm.)	0·425	0·280	0·228	0 630
(per cent)	27	18	14	41

The enzyme activities are expressed as μmoles substrate-change per min. per mgm. protein at 37° C. The total quantity present in all the four fractions is taken as 100 per cent.

Conversion of DL-*m*-Tyrosine to Dopamine in the Rat

THE formation of catecholamines *in vivo* has been demonstrated using phenylalanine[1], tyrosine[2,3], 3,4-dihydroxyphenylalanine (dopa)[2,4], and 3,4-dihydroxyphenylserine[5] as precursors. *m*-Tyrosine (3-hydroxyphenylalanine) has been considered in this laboratory as another possible precursor, for it is decarboxylated by mammalian organs *in vitro*[6] and *in vivo*[7], and its decarboxylation product, *m*-tyramine, is found in normal[8] and phenylketonuric[9] urines, and in urine of subjects who have received an inhibitor of monoamineoxidase[10]. The recent characterization of leptodactyline as the trimethyl-ammonium salt of *m*-tyramine[11] suggests that at least some animal species can form *m*-tyrosine, although this amino-acid has not yet been identified in any natural source.

Table 1. URINARY EXCRETION OF DOPAMINE IN THE RAT

Exp.	Compound administered*	Dose (mgm./kgm.)	Mean-body-weight (gm.)	Dopamine excreted per rat (μgm.)	Recovery of *m*-tyrosine as dopamine (per cent)
1†	None		238	0·7	—

	DL-3,4-Dopa	5	147	162	28·20
	DL-3,4-Dopa	15	172	449	22·50
3	DL-*m*-Tyrosine	50	218	22	0·24
4	DL-*m*-Tyrosine	100	101	25	0·27
	Same, but pre-treatment with reserpine (see text)	100	72	17	0·25

* Injected intraperitoneally in aqueous solution, controls received equivalent volume of saline. Three rats were caged together and their pooled urine was analysed for dopamine fluorometrically (ref. 13).

† In exp. 1 urine was collected for 5 hr.; in exps. 2 and 3, 19 hr.; in exp. 4, 21 hr.

We have found by administering DL-*m*-tyrosine (California Corp. for Biochemical Research, Los Angeles) to rats that excess dopamine (3,4-dihydroxyphenylethylamine) is excreted in the urine. In exps. 1–3 of Table 1, 0·19–0·47 per cent of the dose administered was excreted in the urine as the catecholamine. The urinary catechols obtained in exp. 1 were adsorbed on alumina and eluted with 0·5 *M* acetic acid; fluorescence of the eluate was measured at 335 mμ (activation at 280 mμ) in an Aminco–Bowman spectrophotofluorometer. With these conditions, dopamine fluoresces maximally, but specificity is lost by comparison with the oxidative procedure in which a fluorophore is formed from dopamine, but not from the other catecholamines, the catecholic acids[13], or *m*-tyrosine. This fluorescence, calculated as though it were all due to dopamine, gave a recovery of 0·26 per cent based on the DL-amino-acid; this is to be compared with the recovery of 0·19 per cent, estimated on the same material but using a specific fluorometric method[13]. In two other experiments of the same type the values for recovery were 0·27 and 0·28 per cent by the non-specific, and 0·25 and 0·27 per cent by the specific, fluorescence measurements, respectively. The yield from dopa is much greater (exp. 2).

Descending chromatography of the alumina eluates of exp. 1 was carried out on Whatman No. 3*MM* filter paper, using *n*-butanol/acetic acid/water (7 : 1 : 2), for 18 hr. After drying and spraying with ferricyanide reagent the eluate of urine of rats receiving *m*-tyrosine showed one spot; this was at the same position on the chromatogram as authentic dopamine. The eluate of control urine showed no such spot. *m*-Tyrosine is not adsorbed on alumina under the conditions used for preparation of the eluates.

Nine rats weighing 225–250 gm. were injected intraperitoneally with 200 mgm. of *m*-tyrosine per kgm. 30 min. later they were killed by guillotining, and the kidneys were removed for analysis. These organs contained 0·54 μgm. ± 0·09 (*S.E.*) of dopamine per pair of kidneys. A similar group of nine animals which had received 5 mgm./kgm. of tranylcypromine, a potent monoamine oxidase inhibitor, gave a mean of 1·98 μgm. ± 0·31 (*S.E.*). Control values (3 rats each) were 0·07 μgm. (range, 0·06–0·08) and 0·26 μgm. (0·17–0·30), respectively.

The excess urinary dopamine found after administration of *m*-tyrosine to rats as described could possibly be attributed to release of the amine from storage sites in the tissues. In order to verify this point, rats were injected intravenously with 10 mgm. of reserpine per kgm. to deplete the tissues of catecholamines, and 72 hr. later were given 50 mgm. *m*-tyrosine/kgm. intraperitoneally; controls were treated similarly except that the vehicle alone was substituted for the solution of reserpine injected. Matched groups receiving reserpine or vehicle, but not the amino-acid, were used to correct the values of the groups getting *m*-tyrosine; the level of this endogenous urinary dopamine is very low. It will be noted in Table 1, exp. 4, that the reserpine-treated and placebo rats excreted the same proportion of the administered amino-acid as dopamine. This indicates that a releasing action by *m*-tyrosine on 'bound' tissue dopamine does not play any part in the results obtained here.

The conversion of *m*-tyrosine to dopamine involves (1) oxidation of the ring in the *para* position and (2) decarboxylation. The order in which these occur and the mechanism of the ring oxidation are not known. Microsomal enzymes of the liver are known to oxidize aromatic rings in more than one position, but they do not appear to act in this way on L-phenylalanine[14]. Whether the same is true of *m*-tyrosine awaits further experiment.

This investigation has been supported by a Dominion-Provincial Mental Health Research Grant. Tranylcypromine (*SKF* 385-*A*, *trans*) was generously provided by Smith, Kline and French Laboratories. Philadelphia, Pa.

Reduction of Coenzyme Q by Succinic Acid Dehydrogenase

Crane, Hatefi, Lester and Widmer[1,2] have shown that coenzyme *Q* is reduced by mitochondria or derivative particles like electron-transporting particles, or succinic dehydrogenase complex, and that this reaction is sensitive to antimycin *A*. We have now succeeded in reducing coenzyme *Q* with a soluble preparation of succinic acid dehydrogenase, and this reaction was not sensitive to antimycin *A*.

Table 1. REDUCTION OF COENZYME *Q* BY SUCCINIC ACID DEHYDROGENASE

Assay conditions: 75 μM potassium phosphate, *p*H 7·2; 0·08 mgm. coenzyme *Q* in 0·02 ml. of anhydrous ethanol; 0·25 *M* sucrose to 1 ml. Incubation at 37°

Succinate (μM)	Enzyme (mgm.)	Duration of incubation (min.)	Inhibitor	Percentage of coenzyme *Q* reduced
7·5	0·1	10	None	20
7·5	0·2	10	,,	43
7·5	1·0	10	,,	86
7·5	0	10	,,	0
None	1·0	10	,,	0
7·5	0·45	2	,,	12
7·5	0·45	5	,,	18
7·5	0·45	10	,,	52
7·5	0·45	15	,,	77
7·5	0	15	,,	0
7·5	0·45	10	Antimycin *A* (30γ)	55
7·5	0·45	10	Antimycin *A* (60γ)	54
7·5	0·45	10	None	54
7·5	0·45	16	Antimycin *A* (30γ)	84
7·5	0·45	16	None	85

The enzyme was prepared from pig heart by the method of Neufeld *et al.* (preparation *B*, stage VI)[3]. The enzyme was dialysed at 0° against distilled water for 2 hr. The preparations showed succinic acid dehydrogenase activity, as measured by Slater's method[4], in the presence of methylene blue (12 µl. oxygen per mgm. of protein, per 60 min.), but did not exhibit any cytochrome *c* reductase and succinic oxidase activity. The reduction of coenzyme *Q* was determined by the method of Hatefi *et al.*[2]. The results are given in Table 1.

The results show that coenzyme *Q* is reduced by succinic acid dehydrogenase in the presence of succinate. Since this reaction is insensitive to antimycin *A*, it may be assumed that cytochrome *b* is not involved in this reaction.

A more detailed account of the experiments will be published in *Acta Biochimica Polonica*.

PHYSIOLOGY

Nervous Activity in Relation to the Respiratory Cycle

IN the intact organism the physiological systems should show varying degrees of integration and interaction. Respiration is a cycle which appears likely to bear some relationship to moment-to-moment activity of the nervous system, because of its general biochemical effects, its wide afferent and efferent connexions, and its association with the brain stem reticular system. It is therefore relevant to ask whether changes in nervous activity occur preferentially in any part of the respiratory cycle. An answer can be sought in many facets of nervous function. In the electroencephalogram an abnormal feature very suitable for such study is the recurring, relatively stereotyped complex seen in sub-acute encephalitis[1] and possibly initiated from brain stem structures. A recent study in two cases[2] showed that these complexes arose preferentially at certain parts of the respiratory cycle; and the same obtained for eye blinks and voluntary movements. Further results reported here support the view that this asymmetrical distribution of activity is a more general phenomenon.

The object has been to determine the frequency of occurrence of a particular activity within each 1/10 of the respiratory cycle, a standard reference point on the activity being used for this analysis. The electroencephalogram, respiration and cardiogram were recorded simultaneously on 7, 8 or 16 channel apparatus in more than 40 patients undergoing neuropsychiatric investigation and in 12 normal adults. Respiration was measured unobtrusively with a thermocouple on the nose, and in some instances also by an expanding potentiometer on the chest. The respiratory ink traces showed distinct transition points at the onset of expiration, the interval between adjacent points being taken as a respiratory cycle. For analysis the respiratory tracing was obscured while standard reference points on the activity under study were marked on the trace. Each selected point was later projected on to its associated respiratory trace so that the 1/10 in which it fell could be determined, and frequency distributions compiled. The expiratory onset indicated by the thermocouple was probably not physiologically identical in all subjects or states of consciousness; but this seemed unlikely to produce misleadingly significant results. For statistical assessment the observed frequencies in the 10 intervals were compared (using chi square) with equal expectations at each interval. In each group subjects in which observation departed from expectation at the $< 0·01$ level were considered individually; the sum of the data from the rest of the group was assessed in the same way after a preliminary chi square analysis to ensure that the figures to be summed did not differ significantly.

'Spontaneous' arousal activity of the *K* complex type was studied in 16 subjects in quiet barbiturate-induced or natural sleep under ordinary laboratory conditions, analysis being restricted to those complexes arising without any provoking sound recorded or noted at the time. A masking background noise was used in some instances. The total frequency distribution for the onset of 1,700 complexes appears in Fig. 1*A*. There are two distinct patterns—(*A*) those with a peak in the first 1/10, and (*B*) the remainder; and as seen from the figure these differ essentially by 1/10 phase. Statistically, for 3 subjects with large numbers of arousals, $P < 0·01$; for the remainder summed, $P < 0·01$.

Spindle activity arising apparently spontaneously under the same conditions was studied in 16 subjects. The onset was again used as the reference point, analysis being restricted to activity occurring as a generalized change. In Fig. 1*B* appear distributions for the total (4,530), and for the two divisions (*A*, *B*) split as for arousal activity. The patterns are less striking. Statistically, in 3 subjects $P < 0·01$; and in the remainder summed $P < 0·02$.

Spike and sharp wave activity in barbiturate-induced sleep in temporal lobe epileptics was studied similarly, but the analysis was complicated by the

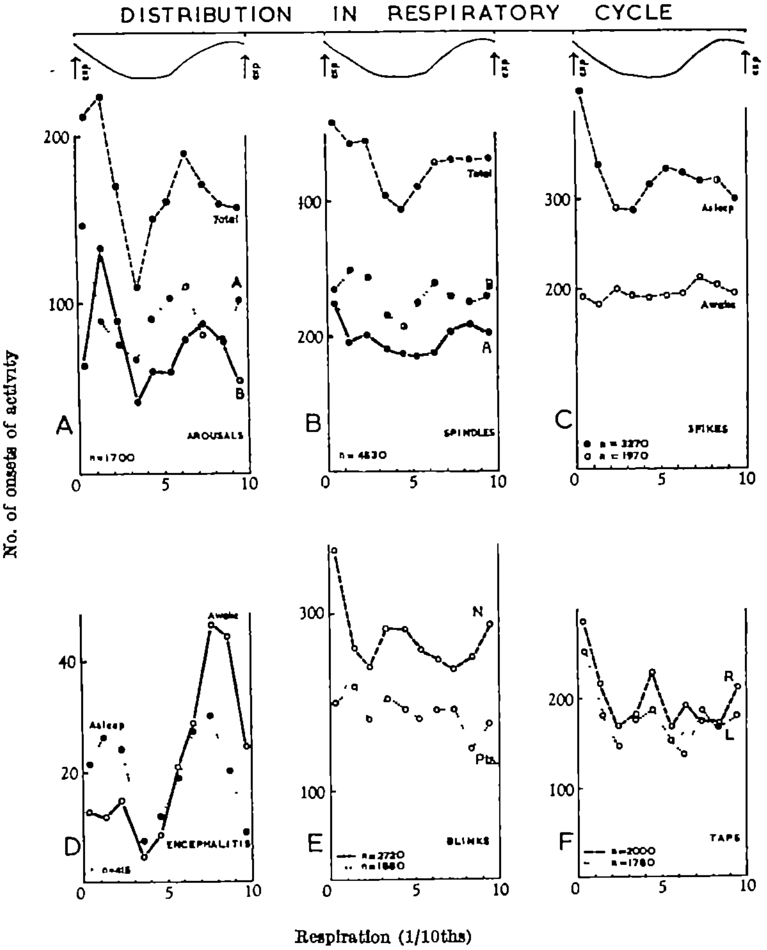

Fig. 1. Frequency of occurrence of events within each 1/10 of the respiratory cycle, taken as from the onset of one expiration (exp.) to the next. The events are the onset of: *A*, arousal activity; *B*, sleep spindles; *C*, spike/sharp wave activity; *D*, complexes in a case of sub-acute encephalitis; *E*, spontaneous blinking in normal adults (*N*) and patients (*Pts.*); *F*, voluntary tapping movements of the hands. (*n*, No. of observations. Total, 20,265)

tendency for the discharges to occur repetitively or in groups. Consistent results were obtained and the distribution of 3,270 discharges in 7 patients is seen in Fig. 1*C* ($P < 0{\cdot}001$). A tumour case provided a clear exception to this pattern. In the waking state there was no such uniform picture, as shown in Fig. 1*C* for 1,970 discharges in 7 patients.

In a case of sub-acute encephalitis the results obtained similarly for the onset of the complexes when awake and asleep are shown in Fig. 1*D* ($P < 0{\cdot}001$). Striking, though not identical, double-peak patterns have been seen in 2 other cases.

Spontaneous blinking was studied similarly in 8 normal adults unaware of the purpose of the investigation and free from visual distraction. Summed distribution for the onset of 2,720 blinks is shown in Fig. 1*E* (*N*). For 3 subjects $P < 0{\cdot}01$; for the summed remainder $P < 0{\cdot}02$. In 7 patients with more frequent blinking and some visual distractions the results were less uniform, as shown also in Fig. 1*E* (*Pts.*).

Voluntary repetitive tapping movements of the hand were studied similarly and the summed results for 10 subjects appear in Fig. 1*F* for right (*R*) and left (*L*) hands. The subjects were requested to tap every few seconds or so at will, preferably non-rhythmically, but without special attention; and the tapping was performed over long periods, interrupted by requests for pauses, changes of hand or frequency. All subjects were unaware of the purpose of the procedure and many that respiration was being recorded. For 2 subjects $P < 0{\cdot}01$; and for the remainder summed $P < 0{\cdot}001$. Fairly rapid rhythmic tapping in one demented and one defective patient showed only traces of this asymmetric distribution.

In natural sleep, dished or double-peak distributions were observed for the onset of slow activity in the presence of a tumour, and for slow activity leading on to spike discharges in focal epilepsy. Preliminary study of the suppression-burst activity of deep narcosis suggests an asymmetric distribution. Spike-and-wave type of epileptic activity showed in sleep a double-peak distribution which could be seen to some extent in the waking state, but not in all cases. A distribution similar to that for sub-acute encephalitis was seen in a lifelong epileptic with unusual recurring complexes associated with eyelid flutter. The double peak distribution may possibly be a basic pattern for some groups of activity. It might be noted that the respiratory distribution of heart beats (*Q* waves) has features in common with the above patterns when sinus arhythmia is present[1].

For any activity the distribution pattern depends on the frequency of repetition and the reference point chosen (changes in this latter producing a 'phase' or horizontal baseline shift). Nevertheless, patterns seen to a striking extent in sub-acute encephalitis are present to a lesser extent in other functions, though these are not necessarily independent of each other; for example, possibly the distributions of spike and spindle activity result from their association with arousal activity, which has much in common with encephalitic complexes. No methodological error has yet been found to account for these results. The possibility must be considered that the respiratory cycle reflects an influence which affects the probability of occurrence of many activities, an influence which, in the electroencephalogram, is best seen in sleep and certain pathological states where discharges may be initiated from brain stem structures. This influence, which need not be excitatory, might affect respiration or be secondary to it; and the reticular activating system would appear of first importance. It might impose a periodic tendency on otherwise sporadic activity, and influence the repetition interval or the likelihood of progression, for example, to a clinical attack. The termination and duration of activity are of interest in this type of study, which may assist the grouping of electroencephalogram phenomena.

Similar investigations of other aspects of nervous activity, for example, reflex and autonomic functions, are relevant.

Changes in Mode of Respiration as an Indication of Level of Awareness

During a study of the peripheral autonomic electroencephalographic and psychological accompaniments of emotional states, it was discovered that frequently a change from thoracic to abdominal breathing, or vice versa, denoted more clearly than the electroencephalograph alone a change in the level of consciousness. The respiratory pattern was demonstrated by means of two expanding straps attached to potentiometer transducers, one around the abdomen and the other around the chest. The electroencephalograph, eye movements, galvanic skin resistance and peripheral vasomotor changes were also recorded, and there was a sound-level indicator.

In the upper example shown in Fig. 1 the subject is drowsy and snores are indicated. The mode of respiration is thoracic. Following a stimulus, the electroencephalograph shows arousal with a train of slow waves of high voltage. Accompanying this there is a change to abdominal breathing. In the lower part of the figure there is a shorter but similar arousal response and a change in the background activity of the electroencephalograph following a snore, but with a longer latency. The mode of respiration again changes to abdominal.

In Fig. 2*A* there is an apparently spontaneous arousal associated with an eye movement and a slight change to abdominal respiration. In Fig. 2*B*, following an external noise there is no arousal response in the electroencephalograph and no change in the background activity, but an eye movement initiates a clear change to abdominal breathing. In Fig. 2*C* there is again an apparently spontaneous arousal response in the electroencephalograph with no associated change in respiration, and to the right of the record a change in skin resistance (*PGR*) is followed by an electroencephalograph arousal and a change to abdominal respiration.

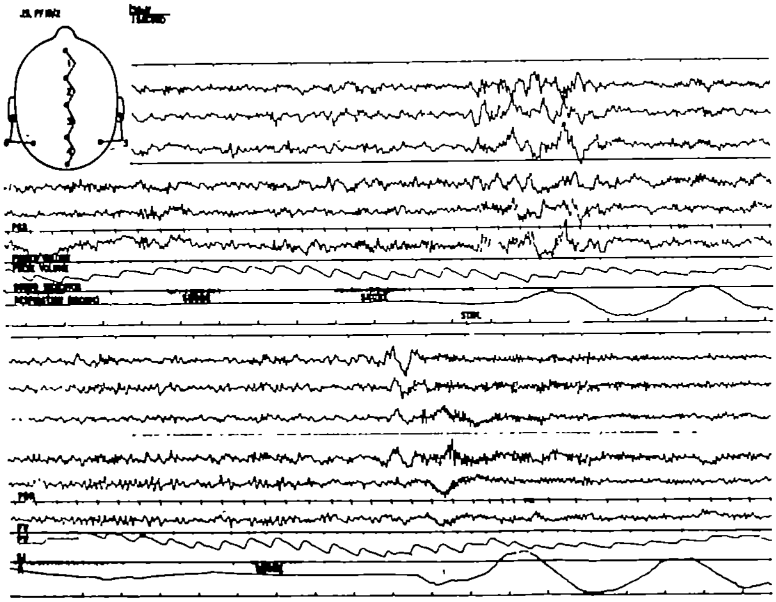

Fig. 1

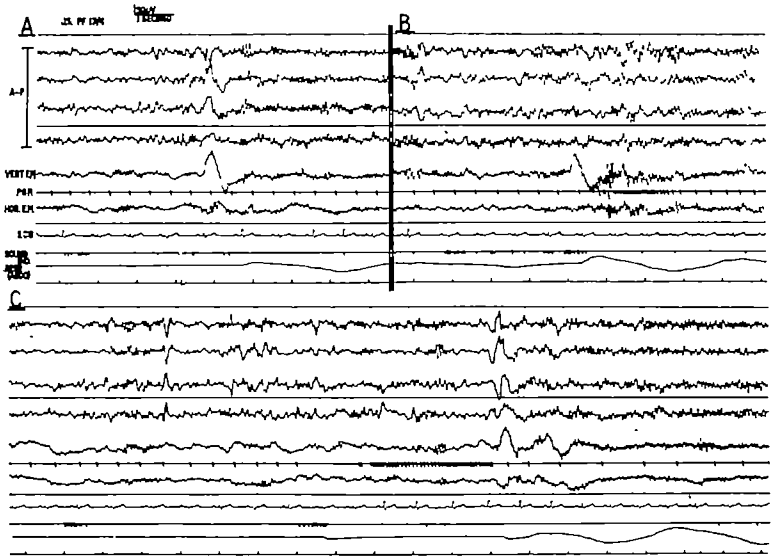

Fig. 2

A consistent change in mode of respiration during sleep as a response to a sound stimulus could be used as objective evidence as to the site of the lesion in deaf children, and may be of value in distinguishing deafness from mental deficiency. It is likely that studies of the arousal system in man might be furthered by close study of associated respiratory changes and also the problems of 'adaptation' and 'apperception' in sleep.

We have observed when using hypnosis that a change in the mode of respiration occurs as the subject becomes hypnotized and that this can be used as the first indication of a change in the state of the subject when there is no other objective evidence. It has been observed that snoring can occur with every clinical appearance of sleep on the suggestion that the subject go to sleep, while the electroencephalograph remains that of the waking state.

The Synchronous Discharge of Apocrine Sweat Glands of the Welsh Mountain Sheep

Evidence that from time to time the apocrine sweat glands of the Welsh Mountain sheep discharge their contents synchronously over a large area of the fleece-covered skin has emerged from the observation that thermocouples attached to the skin anywhere beneath the fleece simultaneously register an occasional and brief rise in temperature which frequently exceeds both ambient temperature and deep body temperature as measured by a thermocouple implanted within the brachio-cephalic trunk[1] (Fig. 1).

The rise in skin temperature cannot be attributed to a change in tissue conductivity, but could be due to the generation of heat at, or near, the surface of the skin, as might occur if an aqueous fluid were abruptly discharged from the skin and absorbed by the fleece, since the uptake of water by wool, which is hygroscopic, involves an exothermic reaction[2-4]. As there is a rise in the humidity of air drawn continuously through a cup attached to a shaved area of skin simultaneously with the rise in skin temperature beneath the fleece elsewhere on the body surface (Fig. 1), while no rise in skin temperature is detected by a thermocouple attached to another shaved area of skin, this appears to be the explanation for the phenomenon.

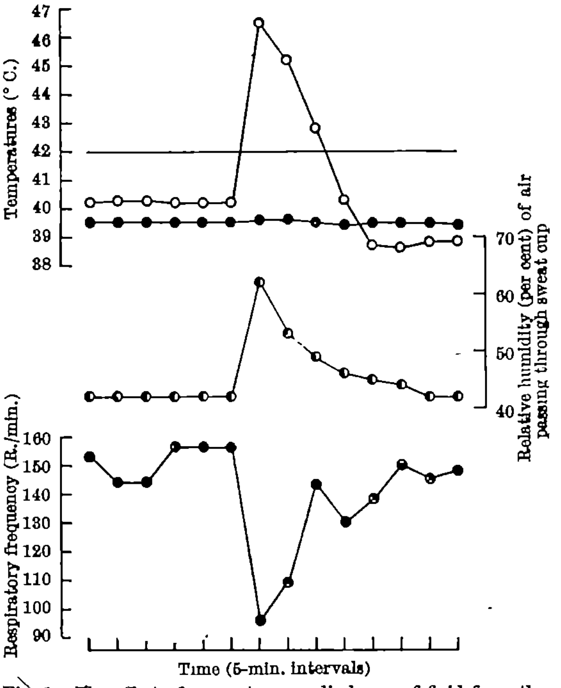

Fig. 1. The effect of a spontaneous discharge of fluid from the skin upon the skin temperature beneath the fleece (○), the relative humidity of air passing through a sweat cup (◐), respiratory frequency (○), and the temperature of the blood supply to the brain (●) at an ambient temperature of 42° C.

Table 1. Effect of Ambient Temperature on the Frequency of the Spontaneous Discharge of the Sweat Glands

Ambient temperature	Sheep No.	No. of 3-hr. exp.	No. of definite discharges	No. of possible discharges
20° C.	36 37 38	4 6 4	2 0 2	0 0 0
		14	4	0
42° C.	36 37 38	4 6 4	15 10 11	0 6 2
		14	36	8

The aqueous fluid is almost certainly derived from the apocrine sweat glands, of which there is one in association with each primary wool follicle[5], as it is known that the glands can be discharged by the administration of adrenaline (ref. 6 and Elliott, J. H., and Ferguson, K. A., personal communication), and the intravenous injection of 10–50 μgm. of adrenaline into a 25-kgm. sheep, under suitable conditions, will cause a similar rise in the temperature of the skin beneath the fleece. However, a second injection of adrenaline 30 min. later, or an injection of adrenaline shortly after a spontaneous discharge, may have only a small, or no, effect. This might be expected if the apocrine glands, following the expulsion of their contents by the contraction of the myoepithelium, are only slowly recharged by the secretory cells.

It is unlikely that the spontaneous discharge of the sweat glands results from a rise in blood adrenaline, as it is accompanied by a small depression (10–15 mm. mercury) in mean arterial blood pressure. A similar depression results from the intravenous injection of 3–5 μgm. adrenaline, but a larger quantity of adrenaline with a marked rise in blood pressure is generally necessary to discharge the sweat glands. The discharge stimulus may be mediated through a sympathetic innervation of the myoepithelium, as has been suggested for man[7].

The spontaneous discharge occurs with greater frequency at higher ambient temperatures (Table 1) but does not depend upon any rise in the temperature of the blood supply to the brain, and performs no obvious thermo-regulatory function. The Welsh Mountain sheep is generally able to maintain thermal equilibrium at an ambient temperature of 42° C. when evaporation is the only available channel of heat loss, whether or not there is a discharge of the sweat glands. Further, at high ambient temperatures, the mass discharge of the sweat glands is accompanied by a depression in respiratory frequency (Fig. 1) which more than compensates for any evaporation from the skin and may cause a small temporary rise in deep body temperature. A possible explanation for the greater frequency of discharges at higher ambient temperatures, which are accompanied by higher skin temperatures but not by a higher deep body temperature, is the local effect of heat on the secretory cells. An increase in the rate at which the secretion is formed would enable the glands to discharge more frequently.

A spontaneous mass discharge of the apocrine sweat glands followed by a quiescent period while the glands are being recharged does not appear to have been observed in other species with histologically similar glands. The ox responds to high ambient temperature[8], and the horse responds to exercise[9], with what appears to be a continuous discharge of sweat, which may be due to a continuous process of secretion, or to the asynchronous discharge of the glands. However, human apocrine glands become refractory to further stimulation after they have been discharged by injected adrenaline[7,10], and it has been suggested that there are synchronous variations in the sweat rate of human eccrine glands, which may be due to the simultaneous contraction of the myoepithelium[11].

It has been claimed that sweating is an important channel of heat loss in sheep when exposed to high ambient temperatures[12–14], and the possibility of a background activity apart from the intermittent mass discharge of the sweat glands remains. However, more recent work[15–17] has shown that panting provides an adequate channel for evaporative heat loss and that sweat gland activity may be of little importance in temperature regulation.

While this synchronous discharge observed in the sheep is not a characteristic of apocrine sweat glands, it may be a characteristic of the more primitive organ from which these and other skin glands have evolved. The skin glands of frogs and mammary glands both respond synchronously to humoral stimuli, and the sweat glands of the sheep, which may serve little or no thermo-regulatory function, may represent a relatively primitive type of apocrine gland.

I am indebted to Mr. A. Barton for his scrupulous experimental assistance and to several colleagues for helpful discussions.

Influence of Calcium on the Potassium-Contracture of 'Slow' and 'Fast' Skeletal Muscle Fibres of the Frog

IT is well known that calcium is an important link in electromechanical coupling; however, there is little information about the underlying mechanism. Our knowledge about the action of calcium on the contracture of heart and skeletal muscles has been extended by a series of important observations[1–7]. Our experiments on electromechanical coupling have led us to investigate the action of calcium on tonic and twitch muscle fibres and to examine the problem whether the property 'slow' or 'fast' of a muscle fibre is influenced or caused by calcium.

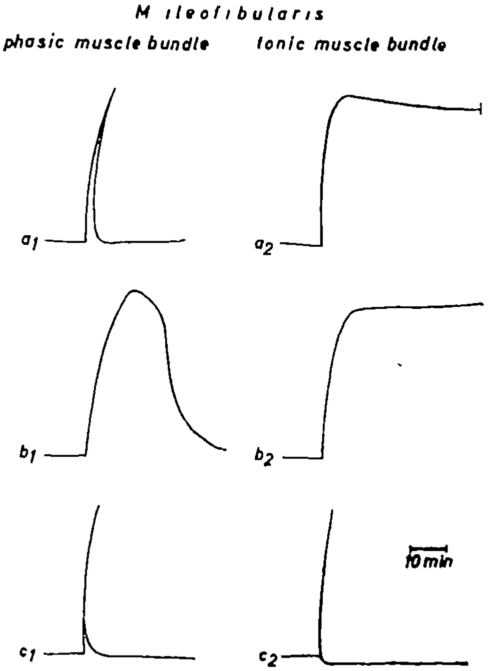

Fig. 1. Contraction (in isotonic potassium chloride solution) of fast (a_1 b_1 c_1) and slow (a_2 b_2 c_2) muscle-fibre bundles from m. ileofibularis of *Rana temporaria* after different preceding treatment (experiment from March 8, 1960). a_1 and a_2: fast and slow bundle after having been kept in normal Ringer's solution for 1 hr. before addition of potassium chloride. b_1 and b_2: these two bundles had been kept in isotonic, calcium-rich Ringer's solution for 1 hr. (88·0 m*M* sodium chloride; 2·5 m*M* potassium chloride; 18·0 m*M* calcium chloride). Potassium chloride solution in this case (93 m*M* potassium chloride, 18 m*M* calcium chloride). c_1 and c_2: These two bundles had been kept in isotonic, calcium-free Ringer's solution for 1 hr. (117·7 m*M* sodium chloride; 2·5 m*M* potassium chloride; 0·0 m*M* calcium chloride) before addition of potassium chloride

Fast and slow muscle fibre bundles from the m. ileofibularis (*Rana esculenta* and *R. temporaria*) were used for our experiments, the results of which are briefly discussed. Fig. 1a shows the typical reaction of a bundle of fast (a_1) and slow (a_2) muscle fibres to isotonic potassium chloride, that is, a rapid decline of the shortening of the twitch fibres and the prolonged contracture of the tonic ones.

Since the membrane potential is identical in both cases—it declines considerably and remains low—this means that there is a quick uncoupling of the process of contraction and depolarization in fast fibres, but this is not the case in slow fibres. Consequently there must be other governing factors. As is shown in the records reproduced in Fig. 1, this mechanism of coupling can be influenced by changing the calcium content of the Ringer's solution, which results in a more or less complete reversal of the specific function of either type of muscle fibre.

Curve b_1 shows the contracture due to potassium of a bundle of fast fibres after a preceding treatment with Ringer's solution of ten-fold calcium content. The reaction has become considerably more tonic. Even more pronounced is the effect of calcium on tonic fibres (curve b_2), which shows a higher and more prolonged contraction than that recorded in curve a_2. Finally, curves c_1 and c_2 show the effect of the absence of calcium on either type of muscle fibre: the contracture declines very rapidly.

This reversal of the function of fast and slow muscle fibres under the influence of varied calcium concentrations is not caused by a specific kind of membrane depolarization. It therefore seems to be the result of a direct action of the calcium on the mechanism of contraction.

The change in the contracting properties of fast and slow muscle fibres under the influence of varying calcium concentrations is not limited to contracture caused by potassium. It is also true for the so-called *Ermüdungskontraktur* and for the twitch. This will be discussed elsewhere.

The difference in the contractile properties of fast and slow muscle fibres suggests wide differences in the fundamental mechanism and ion kinetics.

Further investigations will be required to determine whether fast and slow muscle fibres have a different calcium content (probably through calcium pumps of different effectiveness), and whether the different resting potential (about 85 mV. for fast fibres; 60 mV. for slow fibres) inhibits the permeability of the tissue to calcium ions.

This work was described at a meeting of the German Physiological Association, Freiburg (Germany), on June 9, 1960.

Distribution and Fate of Rose Bengal

IT has been suggested[1] that complexity of the rose bengal plasma decay curve might be due to the uptake, by organs other than the liver, of different components of the dye. Biorck *et al.*[2] and Meurman[3], using commercial rose bengal labelled with iodine-131, obtained results which made this assumption improbable and have interpreted the plasma decay curve by assuming the existence of a reverse flow of dye from liver cells into the blood.

In order to investigate this problem further, a pure component of rose bengal (B.D.H.) was separated by paper chromatography according to Ishida *et al.*[4]. This pure compound has a mauve-pink colour and is not fluorescent; by ascending paper chromatography it has an R_F value of about 0·42 and by descending a value of about 0·47. Maximal absorption of a 0·002 per cent solution was at 548 mμ while for the total dye it occurred at 540 mμ. Labelling with iodine was performed, with slight modifications, according to Liebster and Andrysek[5]. The isolated component contained 41 per cent of the total radioactivity and no free iodine-131 was detectable.

Using this purified labelled rose bengal it was found that the plasma decay curve in the rabbit was precisely the same as when using the original multicomponent labelled rose bengal. This curve is approximately bi-exponential and closer examination shows that each of the two parts of the curve can be resolved into two exponential functions. The percentage disappearance-rates per min. in a typical curve had values of 28·9, 7·4, 1·2, and 0·11. It is concluded that the shape of the rose bengal plasma curve is not due to heterogeneity of the dye but solely to the biological situation.

Little information exists on extra hepatic uptake of rose bengal and no quantitative data are available[6–8]. The dye is bound by serum protein[9] and mostly by albumin[3]. Because trans-capillary passage of plasma protein takes place[10–13] it is likely that some extra-vascular diffusion of rose bengal will occur. It was found in normal rabbits that the amount of dye present in the extra-vascular space is not more than 3–4 per cent of the injected dose (60–80 μc. rose bengal labelled with iodine-131 in 5–10 mgm. carrier in 1–2 ml. of Ringer solution). This finding is supported also by the fact that in Meurman's data[3] about 6 per cent of the dose given is missing, and is most likely to be found in the carcass of the animal. By considering the size of the extra-vascular space[14], and the relative slowness of exchange[11], the later exponentials of the plasma decay curve appear to be explained.

Having to hand a single component of rose bengal it was thought worth while to see if the liver undertakes any biochemical conjugation of the dye as it does in the case of bromsulphalein[15]. Samples of rabbit bile, collected at different times following injection with labelled rose bengal, were subjected to ascending paper chromatography[4]. Only one radioactive spot with practically unmodified R_F value appeared for each sample, thus excluding transformation or conjugation of the dye. This agrees with the recent finding of Kubin *et al.*[16].

The fate of the albumin molecule after the remova of the rose bengal was also investigated. Rabbit albumin, prepared using carboxymethyl cellulose[17] and the elution gradient conditions indicated by Cohen[18], was labelled by the iodine monochloride method[19] with iodine-125 and then incubated with rose bengal labelled with iodine-131 (about 0·7

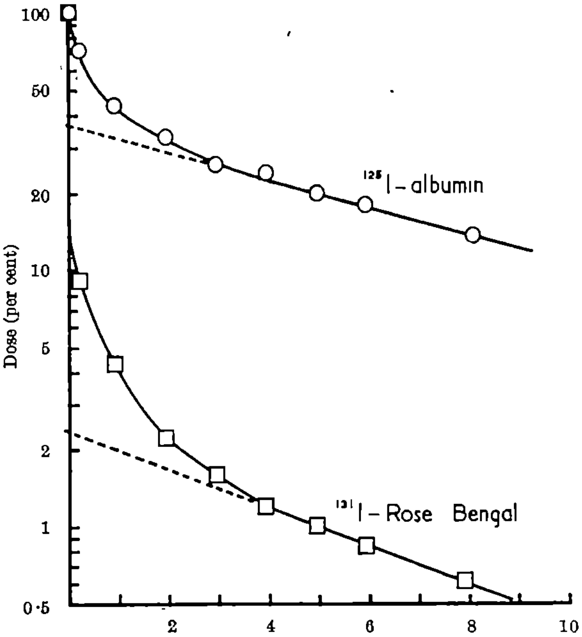

Fig. 1. Plasma radioactivities after injecting ^{131}I-rose bengal–^{125}I-albumin into rabbits

mole rose bengal per mole albumin). After dialysis at 2° C. against saline buffered with $0\cdot01\ M$ phosphate at pH $7\cdot35$, less than $0\cdot5$ per cent of the radioactivity was soluble in 10 per cent trichloracetic acid. The iodine-131-labelled rose bengal / iodine-125 labelled albumin complex was injected into two rabbits and radioactivities were measured in plasma, total body, urine and fæces. Fig. 1 shows that the iodine-131 label disappeared very rapidly from the circulation; it was found quantitatively in the fæces. The iodine-125 label, on the other hand, behaved exactly as it does when attached to normal rabbit albumin[20,21], that is, there was an initial disappearance of about half the albumin into the extra-vascular space and thereafter a steady exponential rate of loss occurred with half-lives of 130 and 140 hr. in the two experiments.

These experiments have demonstrated the lability of the dye–albumin complex and that the binding *in vitro* of rose bengal does not affect the catabolism of the albumin.

The advice and help of Dr. A. S. McFarlane and Mr. R. C. Holloway are gratefully acknowledged.

HÆMATOLOGY

Inherited Hæmoglobin Ionographic Properties in Cotton Rats

A recent comparative study[1] showed that cotton rats (*Sigmodon hispidus*) were more variable, regarding hæmoglobin electromigration properties, than the other species examined. Several cotton rats of different hæmoglobin types were retained as breeders in order to investigate the genetic basis for these differences.

Hæmoglobin ionograms were obtained with Schleicher and Schuell 2043*A mgl* filter-paper strips in a Spinco Durrum type model *R* electrophoresis cell. The conditions of electrophoresis were as follows: $0\cdot0225\mu$ veronal buffer containing 15 per cent glycerol, pH 8 6, 20–26° C., 10 V./cm., 8 hr. duration. The dried strips were stained with bromphenol blue and were scanned in a Photovolt model 525 photoelectric densitometer.

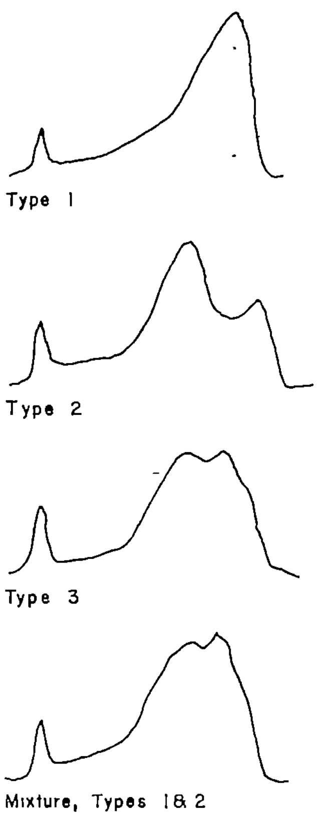

Fig. 1. Scanning curves of cotton rat hæmoglobin ionograms

Absorption scanning curves of the three different types of hæmoglobin ionograms found among cotton rats taken from wild populations are presented in Fig. 1. Among 23 cotton rats collected in Stanly County, North Carolina, 21 had hæmoglobin of type 2 and two had hæmoglobin of type 3. Of 11 cotton rats collected in Colquitt County, Georgia, seven had hæmoglobin of type 2, two had type 3, and two had type 1. Within the limits of resolution obtained, hæmoglobin type 1 seems to be a single component, but type 2 seems to contain two components, a major one plus a minor one of higher mobility. Type 3 is qualitatively indistinguishable, by this technique, from a 1 : 1 mixture of hæmoglobin types 1 and 2.

Protein that did not migrate from the origin is probably cellular debris that remained in the solutions after centrifugation. When hæmoglobin solutions were shaken with toluene or when centrifugation was prolonged these peaks did not appear; however, cotton rat hæmoglobins of all three types tended to precipitate from concentrated solutions, and omitting toluene extraction and shortening centrifugation time resulted in greater resolution.

In Table 1, cotton rat types *A*, *B* and *C* represent individuals that produce hæmoglobin types 1, 2 and 3, respectively. These results show that type *A* mated to type *B* produced only type *C* offspring. Type *C* rats mated to type *C* produced types *A*, *C* and *B*

Table 1. COTTON RAT MATINGS

Matings	No. of matings	Offspring			
		Type *A*	Type *B*	Type *C*	Total
B ♀♀ × *A* ♂	2	0	0	6 ♀♀ 2 ♂♂	8
C ♀ × *A* ♂♂	2	1 ♂	0	2 ♀♀ 2 ♂♂	5
C ♀♀ × *C* ♂♂	5	5 ♀♀	4 ♀♀ 3 ♂♂	6 ♀♀ 8 ♂♂	26
B ♀♀ × *C* ♂	2	0	4 ♀♀ 3 ♂♂	3 ♀♀ 2 ♂♂	12
					51

offspring in the approximate ratio 1 : 2 : 1, respectively. (A chi-square analysis of the actual ratio, 5 : 14 : 7, reveals that greater departures than this from the 1 : 2 : 1 ratio should occur by chance about 75 per cent of the time.) Type *A* mated to type *C* produced only types *A* and *C* offspring. Type *B* mated to type *C* produced only types *B* and *C* offspring. These findings plus the observation that 21 out of 23 rats taken at random in Stanly County, North Carolina, were type *B* (suggesting that type *B* cotton rats breed true) indicate that types *A* and *B* represent the homozygotes and type *C* the heterozygote of at least two contrasting genes. The fact that a 1 : 1 mixture of hæmoglobin from types *A* and *B* rats is almost indistinguishable from the hæmoglobin of type *C* rats suggests that these hæmoglobin genes act codominantly. The genes cannot be sex-linked, for heterozygotes may be of either sex. More data are needed, however, in order to ascertain whether the hæmoglobin locus in cotton rats is simple or complex.

I am indebted to the National Science Foundation for the support of this investigation.

A New Inheritable Property of Human Sera : the InV Factor

Grubb and Laurell[1], Harboe and Lundevall[2] and Harboe[3] have described the serum groups Gma, Gmx and Gmb with the help of some rheumatoid-arthritic sera which were able to agglutinate O Rh+ red cells sensitized with an incomplete anti-D. Also with an anti-D rheumatoid-arthritic serum complex, Steinberg and Giles[4] have discovered a new factor (Gm-like) only present in the Negro sera but absent in the Whites. Ropartz *et al.*[5] have demonstrated that some sera withdrawn from healthy donors could be used for the Gm groups typings ; in fact, such sera sometimes possess a very pure anti-Gm specificity.

In particular, we studied one of these sera, Virm (the clinical examination shows no signs of arthritic diseases and the Waaler–Rose test is positive to 1/64). This serum, withdrawn from a blood donor, has the ability to agglutinate O Rh+ red cells, coated by an incomplete anti-D. We could demonstrate that : (1) some normal sera were able to inhibit its agglutinating power ; (2) this inhibitory power is inheritable and dominant in regard to the non-inhibitory one ; (3) this inhibitory property is contained in the γ-globulin fraction (Burnstein's method) ; (4) its relation with the Gma, Gmb and Gmx factors is actually studied.

This new serum group is temporarily called InV. It is found in 18·52 per cent of the sera of our population chosen from Seine-Maritime, France. Of 324 individuals tested, 60 were found to be InV(+). The inheritance of this factor has been confirmed by the study of 34 matings yielding 74 children. Out of this family material, 25 families with both parents InV(−) had children who were all InV(−). The anti-D used for the red cells coating had the phenotype InV(+). We have found people InV(−) and InV(+) whatever their phenotype regarding the Gma, Gmb and Gmx may be. Hence it seems that this new factor is independent of these other factors. But further research is necessary to disclose a possible linkage. Besides testing 399 Negroes from Dakar we have found 214 of them to be InV(+), that is to say, 53·63 per cent. Among these Negroes, the InV factor has been found when the individuals were Gm-like(+) as well as Gm-like(−). Therefore it looks as if the InV factor is also independent of the Gm-like factor described by Steinberg and Giles. This fact seems to us to be of profound importance, since until now the Negroes have appeared to possess Gm factors quite different from those of Whites. For example, all the Negroes have the phenotype : Gm(a+ b+ x−)[6,7]. Moreover, the Gm-like factor is present only among them. On the other hand, the InV factor is found in the Negro sera as well as in the White sera.

Delayed Hypersensitivity to Homologous γ-Globulin in the Guinea Pig

THE existence in the rabbit of genetically determined antigenic differences ('allotypes') among homologous γ-globulins has been described by Oudin, who succeeded in preparing precipitating antisera against them after prolonged immunization with specific immune precipitates in adjuvants[1]. Considerable work has been done in an attempt to define the number of distinct serological groups and the number of genes controlling them in the rabbit[2]. The allotypic groups have been reported to be located on fragments I and II (as defined by R. R. Porter) of γ-globulin digested with papain[3].

Previous work on allotypes has been confined to the rabbit and to precipitating antibodies, with the exception of a statement by Oudin that he was able to observe some weak intraspecific precipitin reactions in guinea pigs[4]. In the present investigation, it is shown that guinea pigs, immunized with homologous γ-globulin in adjuvants, will rapidly develop a state of delayed hypersensitivity to the immunizing antigen, in the absence of antibody detectable by systemic anaphylaxis.

The experiments were carried out on white guinea pigs weighing 300–450 gm. In each experiment, animals from a single breeder were used which, although not inbred, were fairly homogeneous. γ-Globulin was isolated from the sera of several coloured adult guinea pigs labelled *A–D*. Various procedures were used for isolation—salt fractionation, starch electrophoresis, chromatography—to ensure that the immune reactions observed could be attributed to the γ-globulin component of the serum. The following antigens were used :

Preparation I : guinea pig γ-globulin prepared from the serum of a coloured guinea pig by batch chromatography, by Dr. D. R. Stanworth, University of Birmingham (unpublished work).

Preparation II : guinea pig γ-globulin prepared from the serum of a coloured guinea pig, *D*, by starch electrophoresis.

Preparation III : guinea pig albumin from the same serum as preparation II, by starch electrophoresis. Preparations II and III were kindly prepared for these experiments by Dr. E. Franklin, New York University.

Preparation IV : guinea pig γ-globulin prepared from mixed sera of coloured guinea pigs *B*, *C*, *D* and *E*, by repeated precipitation with 16 per cent sodium sulphate at room temperature.

Preparation V (1–9) : guinea pig γ-globulins prepared from sera of guinea pigs Nos. 17–25, by repeated precipitation with 16 per cent sodium sulphate.

Preparation VI (1–10) : heat-denatured guinea pig γ-globulin prepared by heating sera of guinea pigs Nos. 26–35 at 63° C. for 10 min. and dialysing against distilled water at *p*H 6 ; the precipitate being spun off and taken up in saline.

The antigens diluted in isotonic saline were mixed with an equal volume of complete Difco adjuvant containing 2 mgm. *M. butyricum* per ml. and emulsified. The antigens were injected in a volume of 0·2–0·5 ml. The animals received two immunizing injections of 0·5 mgm. or less of homologous γ-globulin 8–9 days apart in the foot pads. The intradermal test injections were made in the flanks, in a volume of 0·1 ml. The reactions were observed at 2, 4, 6 and 24 hr. All reactions had the appearance and timing characteristic of delayed sensitivity and measured 8–25 mm. in diameter. They were graded as described elsewhere[5].

A series of animals were immunized with their own isolated γ-globulin, native or heat-denatured, to serve as controls (exp. 4). The presence of antibodies was investigated by testing for systemic anaphylaxis.

Irrespective of the method of preparation, immunization of guinea pigs with homologous γ-globulin induces a state of delayed sensitivity which can be observed 10 days after a single injection, but becomes better established after two injections, still in the absence of the anaphylactic state. No reactions are observed with autologous γ-globulin. The ease and rapidity with which guinea pigs can be made to show delayed sensitivity to homologous γ-globulin contrasts with the long time required to raise allotypic antibodies in the rabbit, and may provide a useful approach to the study of the genetic control of allotypes.

Although no attempts were made to investigate the number of allotypic groups in guinea pig γ-globulins, experiment 3 suggests that there are a number of such groups in this species, as there are in the rabbit.

It is not surprising that allotypes, which are weak antigens, give rise in the guinea pig primarily to delayed sensitivity, since in this animal species delayed sensitivity is an earlier and more sensitive immune response than is the formation of serum antibodies, especially after a weak antigenic stimulus[5-7]. It is possible that in man, having the capacity to show easily delayed sensitivity, this type of immune reactivity to homologous or denatured autologous serum proteins may play an important part in disease as a consequence of chance immunization.

Table 1. SEVERITY OF DELAYED INTRADERMAL REACTIONS IN GUINEA PIGS IMMUNIZED WITH HOMOLOGOUS OR AUTOLOGOUS γ-GLOBULIN

Experiment 1. Albino guinea pigs immunized with 0·2 mgm. homologous γ-globulin, Preparation I

Animal No.	Day 10	Day 14	Day 21	Day 28
	40 γgm. Prep. 1	Boost	10 γgm. Prep. I	10 γgm. Prep. I
1	—		+ ±	+ + +

14	+ + +	– ve	–	–
15	+ + +	– ve	+ –	–
16	+ +	– ve	+ –	–

Experiment 3. 5 albino guinea pigs were immunized and boosted on day 8 with 0 5 mgm. of γ-globulin preparation IV (mixed γ-globulin from 4 guinea pigs *B*, *C*, *D* and *E*). They were tested on day 18 with 50 γgm. preparation IV and on day 20 with 1/50 dilution of the four individual sera *B*, *C*, *D* and *E*.

Animal No.	Prep. IV	Sera				Anaphylaxis, 2 mgm. Prep. IV : I-ven.
		B	*C*	*D*	*E*	
36	+	–	–	±	–	– ve
37	+ +	–	±	+	–	– ve
38	+ + ±	±	–	+ +	–	– ve
39	+ + ±	+ +	+ +	+ +	–	– ve
40	+ + +	+ +	+	+ + +	+	– ve

Experiment 4. 9 guinea pigs, Nos. 17–25, were immunized and boosted on day 9 with 0 5 mgm. of their own autologous γ-globulin (preparation V, 1–9). These animals were tested intradermally on day 21 with 50 γgm. of the same preparations. No positive reactions occurred.

10 guinea pigs were immunized and boosted on day 9 with 0 5 mgm. of their own autologous heat-denatured γ-globulin (preparation VI, 1–10). When tested intradermally with 50 γgm. of the same preparation, 9 were negative, one showed a positive (+) delayed reaction, suggesting that autologous globulin could become antigenic upon denaturation. More work is being done to investigate this possibility.

RADIOBIOLOGY

Absorption of Inhaled Radioactive Water Vapour

THE local function of different regions of the lungs can be studied by the inhalation of various gases labelled with oxygen-15. Recently, water vapour has been labelled in this way. Oxygen-15 has a half-life of 2 min. and is produced by a continuous flow process by bombarding nitrogen with deuterons in the Medical Research Council cyclotron in the grounds of Hammersmith Hospital. Details of its preparation have been published[1]. The oxygen-15 is available in nitrogen containing 3 per cent oxygen as carrier at a flow of 0·45 litre per minute. Radioactive water vapour was prepared by adding 4 per cent hydrogen in nitrogen at a flow of 1 litre per minute and passing the resulting mixture over a palladium-type catalyst ('Catalyst *D*'; Baker Platinum Co.). The effluent contained 2 per cent of water as a vapour and had an activity of about 10 mc. per litre. The absence of unconverted oxygen was checked with a mass spectrometer.

Three normal volunteers inhaled two breaths of 1 litre each from a plastic bag connected to a respiratory valve box and mouth-piece. The activity in the lungs and respiratory tract was detected by two pairs of scintillation counters connected in coincidence. Good spatial resolution can be achieved with this arrangement, 95 per cent of the counts coming from a cylindrical core of tissue 4 cm. in diameter, between two opposed counters. Random coincidences were automatically subtracted. The counting methods have been described elsewhere[1].

When the first breath was taken, the counters were arranged over the peripheral lung fields so that the clearance-rate at the alveolar level could be measured, but we were surprised to find that almost no active gas reached the alveoli. For subsequent breaths, the counter-pairs were moved about so that the counting fields included the mouth, pharynx, trachea and peripheral lung fields. Table 1 shows the counting-rates (corrected for radioactive decay) after a typical breath. It can be seen that much of the activity was found in the mouth and mid-trachea, little penetrated to the carina, but virtually none could be detected in the peripheral lung field.

Table 1. COUNTING-RATES AFTER A SINGLE INSPIRATION OF RADIOACTIVE WATER VAPOUR

Site of counting field	Counting-rate (counts/sec.)
Mouth (A.P.)	170
Pharynx (lat.)	120
Upper trachea (lat.)	160
Mid trachea (lat.)	100
Mid trachea (A.P.)	110
Carina (A.P.)	33
Right lung base (A.P.)	3

* The opposed counters were either in front of and behind (A.P.), or on either side (lat.) of the subject.

The rate of removal of the activity from the mouth area after a breath of the gas was measured by fixing a pair of counters at that level for 2 min. During this period, the counting-rate fell by a half, and since this corresponds to the natural decay-rate, the removal-rate must be slow compared with this.

The rapid removal of inhaled radioactive water vapour by the upper respiratory tract is readily explained by exchange with the water lining the tract, but the efficiency of this process is remarkable. The results are in keeping with the observation that 98–99 per cent of inhaled tritiated water vapour is absorbed[2], since this high figure could only be achieved if the anatomical dead space was cleared of the labelled gas. In this respect, radioactive water vapour is perhaps unique, as other gases undergo little exchange in the dead space, hence its name. The results also fit in with the rapid warming and humidification of inspired air in the upper respiratory tract which have been described[3].

An interesting feature of the preparation of the water vapour was the large loss of activity which occurred when the gas was led through about 10 metres of 0·5-cm. bore polyvinylchloride tubing connecting the chemistry laboratory with the investigation room. Under these conditions, the yield was up to ten-fold less than when the gas was collected in a rubber bladder attached to the end of the catalyst tube. This loss of activity can probably be explained by exchange with water absorbed on the surface of the connecting tube in spite of attempts to remove any moisture present by passing dry air through the tubing. Water absorption on surfaces is a common problem in vacuum technology.

We wish to thank Dr. P. Hugh-Jones for help, and the Director and Staff of the Medical Research Council Radiotherapeutic Research Unit for facilities. The work was supported by the Medical Research Council.

Effect of Radioprotective Sulphydryl Compounds on the Oxygen Tension in the Spleen of Mice

IN a previous paper[1] the mechanism of the radioprotective action of the biologically active amines histamine, epinephrine, tryptamine and β-phenylethylamine was investigated. In studying the effect of these compounds on the oxygen tension in the spleen and bone marrow of unanæsthetized mice strong evidence was obtained that a relation exists between the percentage protection against a lethal dose of X-rays afforded by these compounds and the degree of hypoxia caused in the blood-forming organs. Furthermore, it was shown[2] that cyanide also causes hypoxia in the spleen as a consequence of vasoconstriction and that this effect may well explain its protective action in mice.

In the present communication experiments are presented on the effect of a number of protective sulphydryl compounds on the oxygen tension in the spleen and bone marrow of unanæsthetized mice and rats.

The experiments were performed on groups of female *CBA/Rij* mice weighing 18–20 gm. and on male *WAG* rats of 180–200 gm.

Table 1. CHANGES IN OXYGEN TENSION IN THE SPLEEN AND BONE MARROW RESPECTIVELY OF UNANÆSTHETIZED FEMALE *CBA/Rij* MICE, 18–20 GM., AND MALE *WAG* RATS, 180–200 GM., CAUSED BY A NUMBER OF PROPHYLACTICS AGAINST RADIATION. NEUTRALIZED SOLUTIONS OF ALL COMPOUNDS WERE INJECTED INTRAPERITONEALLY IN A VOLUME OF 0·5 ML.

‡ Amino-ethyl-*iso*thiuronium bromide.

? After *l.i.* or *l.d.* means that this condition was present for a short time only to change soon to *s.i.* or *s.d.*, respectively.

[1] Fairly soon followed by *s.d.* or *l.d.*

[2] After a considerable time *l.i.*

[3] Fairly rapidly thereafter *l.i.*

[4] Followed by *s.d.*

The technique of the polarographic estimation of the oxygen tension in the spleen has been described elsewhere[1]. In addition the oxygen tension in the bone marrow of the femur in mice and of the femur and humerus in rats was estimated by a similar method.

The results were found to vary considerably within each experimental group. The different types of response obtained after injection of the protective compounds were divided so far as possible in five classes as follows: *n.s.*, either no effect or a rise or fall not exceeding 10 per cent of the pre-injection value; *s.i.*, a slight increase in oxygen tension between 10 and 40 per cent; *l.i.*, a larger increase exceeding 40 per cent; *s.d.*, a slight decrease between 10 and 40 per cent; *l.d.*, a larger decrease exceeding 40 per cent.

The results of the experiments are represented in Table 1, in which the number of animals belonging to each class is indicated for a number of protective compounds used in doses which were found to protect the animals against a lethal dose of total body irradiation with X-rays. In a number of cases the classification failed, which is indicated in Table 1.

Table 1 shows that in contrast to the effect observed after both the biologically active amines and potassium cyanide the effect of the sulphydryl compounds is subject to considerable variation. However, for most of the compounds studied the oxygen tension shows a tendency to rise rather than to fall. Cysteine at higher (just sub-lethal) doses only causes a decrease in oxygen tension.

A possible exception is cystamine, to which most of the animals react with hypoxia. This is in accordance with the view[3] that cystamine, being devoid of a free sulphydryl group, acts like a biologically active amine. The fact that amino-ethyl*iso*thiuronium bromide behaves like the sulphydryl compounds is consistent with the view that it is converted into mercapto-ethyl-guanidine[4].

In summary, these results strongly indicate that the protection afforded to mice by the sulphydryl compounds is not mediated by hypoxia of the blood-forming organs. Therefore their mechanism of action differs from that of the biologically active amines and cyanide.

A number of investigators have expressed the view that sulphydryl compounds have a protective effect other than the production of anoxia. The most recent observations are the experiments of Lothe and Devik[5] on the rabbit ear, those of Kohn and Gunter[6,7] on *Escherichia coli*, of Grant and Vos[8] on isolated rat thymocytes and of Vergroesen *et. al.*[9] on HeLa cells in tissue culture.

Changes in Radioresistance of Sporulating Cells of *Bacillus cereus*

THE spores of bacilli represent a unique form of living matter capable of surviving many harmful factors of environment and of restoring intense metabolic activity under suitable conditions. The study of individual mechanisms of resistance of spores was directed mainly to the differences in the content of individual constituents of cytoplasm of spores and of vegetative cells.

One of the typical differences between vegetative forms and spores is the different cystine content. Hot trichloracetic precipitate of spores of some bacilli which have been studied contains about 4–5 times as much as this amino-acid as the vegetative cells[1–3]. On the basis of incorporation of cysteine labelled with sulphur-35 and calcium chloride labelled with calcium-45 during sporulation of *Bacillus cereus* on liquid medium, it was observed that the maximum incorporation of sulphur-35 appears about 2 hr. earlier than the maximum incorporation of calcium-45. The period of increased incorporation of calcium-45 is accompanied by the thermostabilization of structure of spores[3]. This observation is in accordance with the data from literature in which calcium bound with dipicolinic acid is assumed to be the main factor of thermoresistance of spores of bacilli[4–8].

The period of the formation of cysteine-rich structure precedes slightly the formation of the refractile structure of spores. A question arises whether the cystine structure contributes in some way to the resistance of spores. With regard to the possible importance of cystine in radioprotection, the resistance of sporulating cells of *Bacillus cereus* (NCIB 8122) to X-rays was examined. A liquid medium containing tryptic casein hydrolysate (0·3 per cent), glucose (0·1 per cent) and traces of some ions was used for cultivation, free spores having been used as inoculum. A vibration stirrer (100 oscillations/sec., amplitude 1 mm.) was used for splitting of chains, normally formed in this strain, and for homogeneous distribution of the air introduced into cultivation vessel. Practically only pairs of cells were present during the stationary phase of cultivation. Continually harvested samples of culture diluted with $M/40$ phosphate buffer to adequate concentration ($1 : 10^5$) were irradiated by Machlett *AEG*-50-*T* röntgen ray tube (50 kV., 40 m.amp., 0·1 mm. aluminium) in dishes (diam. 23 mm.) equipped with electromagnetic stirrers. On the basis of inactivation curves of vegetative cells and of free spores of this strain of *Bacillus cereus*, the radiation dose corresponding to 120 kr. was chosen. For detection of the loss of thermosensitivity of sporulating cells the aliquots were heated to 65° C. for 15 min. The number of surviving forms was determined in either case by plating procedure, non-treated suspension being used as control. As a recovery medium Difco nutrient agar was used. The percentage of spores was determined by direct microscopic observation and counting. The term 'refractile spores' is used for the more or less refractile areas of cytoplasm of the size and shape corresponding to spores, with somewhat diffuse rim. Cystine content was determined in acid hydrolysates of hot trichloracetic precipitates[3] by means of Shinohara's method[9] using phospho-18-tungstic acid.

The results are given in Fig. 1. They show that the radioresistance of sporulating cells appears simultaneously with the formation of cystine structures. Appearance of radioresistance is closely followed by the formation of refractile structure. The thermostabilization proceeds only after the fully refractile structure has been formed. With regard to the presence of pairs of cells in the culture, the results should be accepted as rather qualitative than quantitative. The correlation observed, however, between appearance of radioresistance and formation of cystine structure seems to be important.

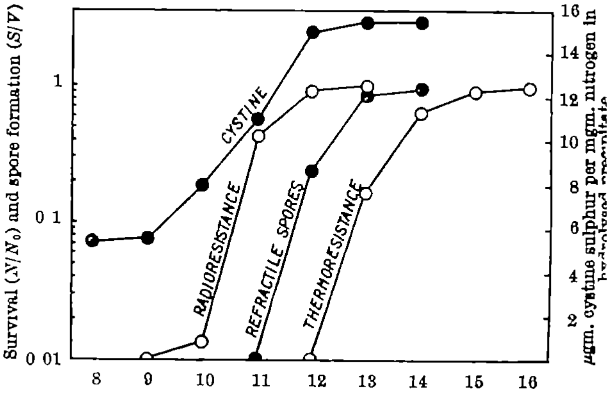

Fig. 1. Changes in radioresistance, cystine content and thermosensitivity of sporulating cells of *Bacillus cereus*. N, No. of surviving pairs of cells; N_0, No. of all pairs present; S, No. of cells with spores; V, No. of all cells present

Practically no cysteine has been found; only cystine is present in hot trichloracetic precipitates of spores of bacilli[3]. As the presence of disulphide linkages can be expected in proteins of spores, mention should be made of the role of this bond in radioprotection. According to results of paramagnetic resonance studies of X-irradiated proteins[10–12] the disulphide bond seems to have the function of a powerful electron donor. Whenever in proteins the electron is knocked out by ionizing radiation the vacancy created is assumed to be filled by an electron borrowed from a cystine group. The formation of mixed disulphides with protein SH—groups was demonstrated with typical radioprotective agents such as cystamine, cysteamine, etc.[13], and the radioprotective efficacy of these compounds is directly correlated to their ability to form disulphides[14]. It can, therefore, be expected that even in spores the disulphide groups play a prominent part in radioprotection of proteins. The cystine-rich protein structure, being localized in the integumental fraction of spores[3], can serve as a carrier for some important enzymes which were observed to be attached to the envelopes of spores[15,16].

HISTOCHEMISTRY

Effects of Nitrogen Mustard on the Histochemistry of Mouse Lymphocytic Leukæmia *L* 1210

THE possibility of detecting chemical (histochemical) changes prior to discernible morphological changes in leukæmic cells following chemotherapy and the attempt to determine the emergence of cellular resistance to a given chemotherapeutic agent provide the basis of the present work.

Isotransplants of acute lymphatic leukæmia (*L* 1210)[1] and sub-lines resistant to 8-azaguanine developed in the Battelle Memorial Institute by the use of 8-azaguanine[2] in *DBA* and *DBF*1 hybrid mice were employed. A total of 80 animals were examined during the course of this work. An inoculation of 0·2 ml. of diluted peritoneal fluid made to approximately 100,000 cells was injected intraperitoneally into host mice; survival-time was between 8 and 9 days after inoculation. Peritoneal fluid was obtained on the 8th day and routine films and supravital preparations prepared. Immediately following this step the animals were injected with 0·05 mgm. nitrogen mustard in 0·1 ml. of distilled water (an *LD*50 for a 20-gm. mouse)[3]. At 15 min. and 1 hr. following injection samples of peritoneal fluid were withdrawn from each animal and films prepared Each animal served as its own control, and additional controls were used consisting of intraperitoneal injections of 0·1 ml. of distilled water.

The following histochemical methods were employed: (1) the DDD method for protein-bound sulphydryls[4]; (2) the indoxyl acetate method for non-specific esterase[5]; and the periodic acid–Schiff method for 1,2 glycols. Routine Wright's stained films and supravital preparations examined with the phase microscope were used for morphological evaluation.

The lymphocytic cells exhibited a strong reaction for sulphydryls localized in their cytoplasm, nucleoplasm and chromatin (Fig. 3). However, very occasionally morphologically intact lymphocytic cells were observed in the peritoneal fluid, which exhibited appreciably less reactivity for sulphydryls than the vast majority of leukæmic cells in the specimen (Fig. 4). In most instances, within 15 min. following the injection of nitrogen mustard there was a marked reduction in reactive sulphydryls present in all leukæmic cells (Fig. 5). This change in the sulphydryl reactivity occurred before the first morphological signs of cellular damage (Figs. 1 and 2), which usually appeared between 1 and 1½ hr. after the administration of the drug. The sulphydryl reactivity of the leukæmic cells present in one of the leukæmic sub-lines resistant to 8-azaguanine appeared less than that observed in the leukæmic cells in the non-resistant strains and other 8-azaguanine-resistant sub-lines. These cells too revealed a reduction in sulphydryl reactivity following nitrogen mustard, although the apparent degree of reduction was less than in the non-resistant strains. Esterase activity demonstrable in the lymphocytic cells with the indoxyl acetate method appeared to increase following the administration of nitrogen mustard. Increased activity as compared with controls was noted at both the 15-min. and 60-min. periods after therapy. Glycogen was not demonstrable in the leukæmic lymphocytes, although a few saliva-resistant periodic acid–Schiff-positive granules were present in their cytoplasm. Periodic acid–Schiff reactivity did not change following injection of nitrogen mustard.

Fig. 5. Lymphocytic cells 15 min. following intraperitoneal injection of nitrogen mustard. Note the decrease in sulphydryl reactivity as compared with control specimen (Fig. 3). Reduced from × 3,000

This preliminary study indicates that chemical changes do occur and occur quite rapidly in mouse leukæmia cells of the *L*1210 strain following nitrogen mustard therapy. Certain histochemically demonstrable changes were noted in the leukæmic cells following nitrogen mustard and before apparent morphological alteration. The possibility of nitrogen mustard binding to available sulphydryl groups present in the leukæmic cells[6,7] seems likely, and may be the mechanism accounting for the decreased sulphydryl reaction given by these cells following nitrogen mustard. The possibility of histochemically distinct sub-lines of leukæmia and the possibility of histochemically detectable resistant cells in cell populations of non-resistant strains warrant further detailed study.

We wish to acknowledge the Battelle Memorial Institute for providing the animals employed in this investigation.

Steroid-3β-ol-Dehydrogenase Activity in Fœtal Leydig's Cells

THERE is a considerable quantity of evidence demonstrating that the fœtal testis produces a hormone responsible, for example, for the freemartin effect[1]. Explantation of fœtal rat testes has shown that secretion of the hormone begins when the fœtus is 15–16 days old[2,3]. Morphological differentiation of the Leydig cells begins during the same period, the interstitial spaces being filled by closely packed polygonal cells containing periodic-acid–Schiff-positive material[4].

Although morphological observations thus favour the view that rat's Leydig cells are active and secreting from the third intra-uterine week, there is a lack of direct evidence for the presence in the testis of steroids or other substances leading to androgen formation.

In the work reported here a histochemical method[5] was used for the demonstration of steroid-3β-ol-dehydrogenase activity in the fœtal interstitial cells of the rat testis. This enzyme has been shown to play a basic part in the formation of the non-benzenoid steroid hormones[6]: consequently, its activity in the testis can be taken as an indicator of the hormone synthesis in it.

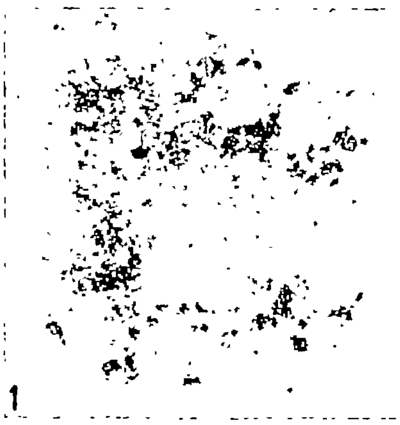
Female rats on heat were mated for 2–4 hr. Fœtuses were removed at intervals from 15 days after the mating, and either the whole fœtuses or their abdominal parts were rapidly frozen. Fresh sections were cut at 25μ with a cold microtome and stained with hæmatoxylin and eosin. Subsequent sections were incubated for the demonstration of the dehydrogenase activity. Dehydro*iso*androsterone in a concentration of 0·03 mgm./ml. served as the substrate and sections were incubated at 37° C. for ½–1 hr.

A positive dehydrogenase reaction was obtained in the rat fœtal testis from the fifteenth day of fœtal life. The interstices of the testes could then be identified with reasonable accuracy. In these, groups of cells giving a positive dehydrogenase reaction could be observed (Fig. 1). The sex cords did not show any enzyme activity at all. The formazan precipitate was finely granular in the round polygonal cells of the interstitial spaces, but a diffuse reddish diformazan staining of the interstices was also constant.

From the fifteenth day of pregnancy to a few hours after birth the histochemical reaction for steroid-3β-ol-dehydrogenase remained qualitatively similar, but quantitative changes could be noticed. The interstitial cells became more numerous and more closely packed, and, hence, the positive formazan deposition was more pronounced (Fig. 2). Formazan was still in the interstitial cells as a granular precipitate, and the germinal epithelium remained unstained. No certain increase in the intensity of staining of the individual Leydig cells towards birth could be observed. A positive dehydrogenase reaction occurred also in the Leydig cells of testes of rats killed a few hours after birth. There, the sex cords comprised a relatively larger portion of the testicle than during the fœtal life, and the positive interstitial cells were correspondingly more separated; but the dehydrogenase activity was otherwise unchanged in its localization and intensity.

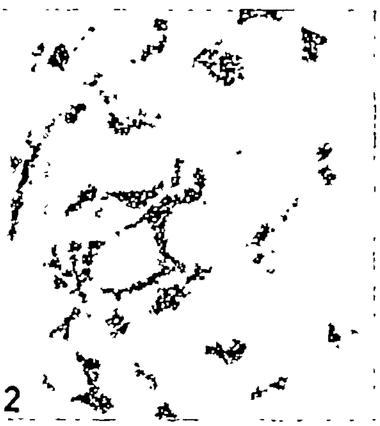
The present observations give histochemical support to earlier findings of hormonal activity of the fœtal testes. It is of special interest to note that the steroid-3β-ol-dehydrogenase activity was found to continue from the fifteenth day to birth without any obvious changes in the enzyme activity in the individual Leydig cells, although the relative volume and number of these cells much increased during this period.

It has been proposed[4] that the different morphological appearance of pre- and post-natal Leydig cells would indicate different modes of secretion before and after birth. Our present findings show, however, that there is at least one important enzyme catalysing the synthesis of steroid hormones common in fœtal as well as in adult rat testicles. This does not, of course, prove that the fœtal testicular product was identical with the adult testicular hormone[7].



1

Fig. 1. Steroid-3β-ol-dehydrogenase activity in the testis of a rat fœtus, fifteenth day of fœtal age. Granular formazan deposits are visible in the interstitial spaces, the sex cords are unstained. (× *c.* 127)



2

Fig. 2. Testis of a fœtus of the eighteenth day. The Leydig cells are more numerous and further differentiated; the enzyme activity is clearly localized in the interstitial cells only. (× *c.* 77)

PATHOLOGY

Mast Cells and Fibrinolysin

During the investigation of human tissues for fibrinolytic activity the presence of a fibrinolytic substance was detected in a specimen of a spleen. This was a case of splenic mastocytosis previously reported[1] in which there were many mast cells and a high concentration of histamine and heparin in the splenic tissue.

We investigated eighteen fresh samples of human spleens obtained at autopsy for the presence of plasminogen activator and plasmin-like activity using the selective and quantitative methods of Astrup, Mullertz[2] and Albrechtsen[3]. The fibrinolytic activity was recorded by measuring the diameter in sq. mm. of the products of tissue potassium thiocyanate extracts on standard bovine fibrin plates (heated and unheated). According to this method, the unheated bovine fibrin plates are reactive to both plasminogen activators and plasmin-like substances, whereas the heated plate reacts only to plasmin. It thus becomes possible to distinguish between plasminogen activators and plasmin or plasmin-like activity.

Potassium thiocyanate extracts of eighteen samples of eighteen different human spleens were assayed for fibrinolytic activity. Of the eighteen splenic extracts, only four showed some activity on heated and unheated plates but this activity was never equal to or greater than that activity of the mastocytotic spleen discussed in the above-mentioned case. Since the spleen containing mast cells had been kept frozen for more than a year when tested for fibrinolytic activity, it was felt that further work would be necessary to evaluate properly this fibrinolytic property.

It was decided to conduct additional studies on various tissues including mast cell tumours in dogs. All the dog tumours had portions removed for pathological examination. These were examined by hæmatoxylin and eosin stain and special stains for mast cells such as luna, toluidine blue and Bismarck brown.

All potassium thiocyanate extracts of dog mastocytomas reacted on unheated plates. On heated plates these extracts possessed little or no activity. One of the cases, a mast cell sarcoma, showed more tissue activator activity than any other tissue examined by us up to date. The tissue activator was found in varying amounts in dog tumours which contain little or no mast cells.

A different pattern of fibrinolytic activity emerged when carefully weighed samples of mast cell tumour tissue were placed on heated and unheated bovine fibrin plates[4,5]. All primary samples of mastocytoma tissue reacted on heated and unheated plates. It was interesting to note that the second and third recurrence of a mast cell sarcoma failed to lyse the heated fibrin plates. No other tumour, whether it was benign or malignant, lysed the heated fibrin plate. These observations are reported in Table 1.

Table 1. Fibrin Plates

Type of dog tumour	Unheated	Heated
Mast cell sarcoma		
Original	+++	+
First recurrence	+++	++
Second recurrence	+++	neg.
Third recurrence	+++	neg.
Malignant melanoma	++	neg.
Mast cell tumour	+++	+++
Mast cell tumour	+++	++
Myosarcoma	neg.	neg.
Breast fibro adenoma	++	neg.
Perianal gland adenoma	neg.	neg.

In accordance with interpretations of the above findings, it appears that these mast cell tumours contain a plasmin-like substance which dissolves both heated and unheated plates.

A study was made of the intracellular distribution of the fibrinolytic activity of the mast cell sarcoma noted in Table 1. Tissue activator was found in the low-speed sediment, the mitochrondrial and microsomal fractions. There was little or no activity associated with the soluble fraction. The microsomes contained the greatest concentration of tissue activator. A significant amount of plasmin-like activity was associated with the low-speed sediment.

Pyridine Nucleotide Metabolism in Heliotrine Poisoning

It has been claimed[1] that failure of activity of a group of pyridine nucleotide - linked respiratory enzymes is an important factor in the acute hepatotoxic action of the alkaloid heliotrine, a member of the pyrrolizidine (*Senecio*) group. The respiratory effect occurred between 16 and 20 hr. after administration of the dose, and reactivation of the non-respiring mitochondria was obtained by addition of diphosphopyridine nucleotide (DPN) to the incubation medium.

Direct estimation of DPN and DPNH in liver homogenates of rats injected intraperitoneally with 320 mgm./kgm. body-weight of heliotrine was carried out by the alcohol dehydrogenase method[2], and a progressive fall to one-half of control values occurred over the period critical for respiration (Table 1). The assay method was not sufficiently sensitive for reliable determinations of mitochondrial DPN, although considerable reduction was observed over the same period.

Table 1. MEAN VALUES (μGM./GM. WET WEIGHT) OF LIVER HOMOGENATES OF RATS TREATED WITH HELIOTRINE AT VARIOUS TIMES PRIOR TO KILLING COMPARED WITH CONTROLS

Control	Heliotrine-treated		
	10 hr.	17 hr.	24 hr.
350	300	235	175

The possibility that heliotrine might reduce the capacity of the liver to synthesize pyridine nucleotides was therefore investigated. Initially, the DPN pyrophosphorylase activity of isolated nuclei[3,4] from control and heliotrine-treated rat liver was measured[5], and showed a definite but minor fall (Table 2).

Table 2. COMPARATIVE RATES OF DPN SYNTHESIS BY LIVER NUCLEI FROM CONTROL AND HELIOTRINE-TREATED RATS (μMOLE DPN/HR./10^{9} NUCLEI)

Animal	11 hr.	15 hr.	19 hr.
Control	23·1	22·7	21·7
Heliotrine-treated	19·4	17·5	13·1

Inasmuch as *in vitro* conditions, with optimum concentrations of substrate, might not reflect the full extent of an *in vivo* reduction of DPN synthesis, the degree of increase of liver DPN after injection of nicotinamide[6] was determined with control and heliotrine-poisoned animals. In the strain of Wistar rats used, an injection of 500 mgm. nicotinamide/kgm. body-wt. raised liver DPN several fold within 4 hr., to a limiting value which was maintained for many hours (Table 3).

Table 3. EFFECT OF NICOTINAMIDE (500 MGM./KGM. BODY-WEIGHT) ON LIVER DPN (μGM./GM. WET WEIGHT). EACH VALUE IS A MEAN OF DETERMINATIONS ON THREE DIFFERENT ANIMALS

Control	Nicotinamide-treated			
	4 hr.	8 hr.	12 hr.	18 hr.
285	810	1,015	1,020	915

With the animals pretreated with heliotrine, the ability to respond to a nicotinamide injection was depressed (Table 4), supporting the results with isolated nuclei (Table 2).

Table 4. MEAN LIVER DPN-LEVELS (μGM./GM. WET WEIGHT) 4 HR. AFTER NICOTINAMIDE INJECTION IN RATS PRETREATED WITH HELIOTRINE. TIMES REFER TO DURATION OF HELIOTRINE TREATMENT PRIOR TO KILLING ANIMAL

Control	Heliotrine-treated				
	4 hr.	14 hr.	18 hr.	20 hr.	24 hr.
810	750	715	580	545	375

In further experiments in which heliotrine-treated animals were given repeated injections of nicotinamide prior to killing, thus maintaining homogenate concentrations of DPN above normal values, the mitochondria failed to oxidize citrate, α-oxoglutarate and β-hydroxybutyrate unless DPN was added to the Warburg flasks. Chelating agents were ineffective.

Thus, although heliotrine produced a definite reduction of DPN synthesis at the 14–24 hr. period, this effect was not great enough to account for the complete failure of pyridine nucleotide-linked respiration observed at this time, and which still occurred even when homogenate DPN values were maintained above normal levels by administration of nicotinamide.

These observations support the hypothesis that failure of cell respiration in heliotrine poisoning is due to inability of the mitochondria to maintain effective local DPN-levels at enzymatically active foci, rather than to reduction of pyridine nucleotide synthesis.

This investigation was supported by a research grant from the Anti-Cancer Council of Victoria.

ANATOMY

Properties of Stressed Bone

DURING the past two years I have been investigating experimentally and histologically the relationship between stresses upon the skull, especially its sutures, caused by and transmitted through the masticatory apparatus.

The animals used in these experiments were the common South African vervet, *Cercopithecus aethiops*, and the stresses applied on the intact heads of the dead monkeys were by means of many ordinary elastic bands stretched around the skull and mandible.

Sections taken through various suture systems and the tooth-bearing parts of the jaws were fixed in 5 per cent formo-saline and decalcified in nitric acid. The sections were then treated with several of the conventional stains, including Masson's stain.

The pattern of green, reddish-brown and the mixture of these colours was so bizarre that it appeared at first to be completely random; but repeated instances of alterations in the colour from green to reddish-brown were found to be systematically recurring in the bones. They occurred according to whether or not stress had been applied to or transmitted through the bone, in that particular region.

When Masson's stain combination is applied to a section of unstressed bone the calcified tissue stains green. If the section passes through an area stressed in the manner stated above the colour of the stressed region is found to be reddish-brown.

The regularity of this localized colour change was noted and then Nicol's prism demonstrated that the normally green staining bone does not transmit light, but that the stressed reddish-brown staining bone now transmits light. Clearly a fundamental physical change had accompanied this profound alteration in staining reaction.

Lest the stain itself should be responsible for the physical change, serial sections of the same specimen were examined for birefringence. Both unstained sections and those stained with hæmatoxylin and eosin (which display no such colour differentiation as exhibited by the Masson-stained specimens) are found still to demonstrate the birefringence caused by the preceding stress.

Sections of the neurocranial bones, which have not been stressed experimentally prior to preparation and Masson's staining, sometimes show an outer plate to which muscles are attached and which exhibit a reddish-brown staining accompanied by birefringence while the inner table is almost entirely green. Where the inner table happens to be reddish-brown it too is birefringent.

Similar changes in the birefringence and staining properties of stressed bone have also been demonstrated in the long bones of vervet monkeys. This indicates that the changes brought about *in vitro* probably also occur *in vivo*. If so, these physical changes in bone must be reversible and perpetually recurring according to the stresses exerted by external forces such as those applied experimentally here or by forces such as those which are developed during muscular activity.

This communication has been prepared to direct attention to some of the changes that occur in bone as a result of being stressed. These changes may have an important bearing on the growth and repair of bone.

BIOLOGY

Transfer of Tolerance to Skin Grafts in F_1 *C57B*1 Inbred Mice

Co-existence of adult animals in experimental parabiosis is followed in due time by 'immunological neutralization' as revealed in tolerance to reciprocal skin grafts. Nakic and Silobrcic[1] observed in rats of different breeds that even after 5 days of parabiotic union homografts survived a longer time than in control animals. Skowron-Cendrzak and Konieczna-Marczyńska[2] reported that the skin homografts of white, non-related mice 'took' permanently after seven weeks of parabiosis. Rubin[3] and Martinez *et al.*[4] found parabiotical neutralization in hybrids of two inbred mice-strains united with individuals of one of the parental breeds. The survival-time of grafts of separated mice parabionts depends upon the length of time of parabiotic union. Similarly, it has been possible to obtain with the help of parabiosis permanent skin isografts in mice characterized by the strong sex-antigen which normally counteracts successful male skin transplantation to the female[5,6]. The duration of parabiosis necessary to evoke neutralization depends upon the degree of antigenic differences between the united individuals. It was shown that in *C57B*1 inbred mice which only differ in sex-antigen, skin grafts from the male to the female performed one week before union may already 'take' permanently[7].

The mechanism of neutralization has not yet been fully elucidated and can be conditioned by such different factors as trauma, enhancement, immunoparalysis and immunological unresponsiveness in adults. The induction of tolerance takes place only if the vascular connexion between the joined animals is established, and a constant reciprocal exchange of a great quantity of antigens exists. In long-term parabiosis between the individuals of two inbred strains of mice (*CBA*,*A*) in which neutralization was lacking, there was never any vascular connexion between parabionts (unpublished work).

The purpose of the work reported here was to establish whether the tolerance to male skin isografts acquired in females during parabiosis can be transmitted to the F_1 generation.

Mice of the inbred *C57B*1 strain imported by our Department three years ago from the Institute of Animal Genetics, Edinburgh, served as material. Parabioses were carried out, always uniting females with isologous males (sisters with brothers). The animals were 4–6 weeks old. One week after the establishment of parabioses, skin grafts were exchanged between the respective members of each parabiotic pair. Whole-skin grafts taken from the back measuring 2 cm. × 2 cm. and rotated 180° were kept in place by sutures. All skin isotransplants were successful. After 1–10 weeks the parabionts were separated and kept in pairs in order to obtain the F_1 generation.

Out of thirty-four F_1 females on which, at the age of 4 weeks, the male brother skin was transplanted, in two cases the grafts were accepted permanently. These grafts were held until the death of the animals (133 and 140 days respectively). In all other females (32) the great majority of isografts survived significantly longer than in controls ($t = 4 \cdot 51$; $P < 0 \cdot 01$). The end of the survival-time was taken to be when the first signs of incompatibility reaction appeared. The control group consisted of fifty *C57B*1 females, 4–6 weeks old, on which the skin taken from isologous male donors of the same age was transplanted. In fourteen females, 2–3 weeks after the first graft, the second-set grafts from the same males were performed. A much shorter survival-time of the second-set grafts corroborates the results obtained by Eichwald *et al.*[8] and reveals the immunological nature of the graft rejection.

The results of isotransplantation in control as well as in experimental mice are shown in Table 1.

Table 1. Survival-Time (days) of ♂ to ♀ Skin Isografts in Strain *C57B*1 Mice

Group		No. of animals	Range	Mean	Standard deviation
Control	First graft	50	12–18	15	± 1 5
	Second graft	14	6–11	7 6	± 1 3
Experimental	First	32	14–49	21	± 9·1

In transmission of tolerance to the F_1 generation the duration of union of parental individuals plays no part. This is evident from the fact that permanent acceptance of the male skin grafts was observed in one of the F_1 females of which the parents had only been united during one week. Similarly, the length of time after separation of parabionts probably has no influence on the transmission of tolerance. The second female, permanently tolerant to the male skin graft, belonged to the animals of the F_1 generation, which were born not earlier than 8 months after the separation of the parabionts. From one and the same parental pair and even from only one individual of them, females can be born which are either completely tolerant, incompletely tolerant or which reject male skin within the same period of time as the control animals do.

At present further experiments are being carried out on isografts of the F_1 and F_2 generation in order to elucidate both the mechanism of parabiotic neutralization and the mechanism of tolerance transmission.

Perfect Stages of *Fusarium oxysporum* and of *Fusarium solani* f. *pisi* still Unknown

A YEAR ago Buxton[1] reported the development of red, *Nectria* perithecia after ultra-violet irradiation of a culture of *Fusarium oxysporum* f. *pisi* (Linf.) Snyd. and Hans. He stated that the fungus causes typical wilt of pea, was re-isolated from the reddened vascular tracts of wilted plants and that, therefore, there could be little doubt but that this homothallic *Nectria* is the perfect stage of that particular wilt-inducing *Fusarium* isolate (that is, *F. oxysporum* f. *pisi*).

Recently, Gordon[2] has taken issue with Buxton's claim, pointing out quite clearly and correctly that *Nectria* (=*Hypomyces*) is well known as a perfect stage of some clones of *F. solani* (Mart.) App. and Wr. emend. Snyd. and Hans., but that for various reasons it would not be expected as a perfect stage of *F. oxysporum*.

We have examined a culture of Buxton's fungus, containing the *Nectria* perfect stage, which had been deposited with the Commonwealth Mycological Institute at Kew. We find that this fungus is a typical, homothallic *Hypomyces solani* Rke. and Berth. emend. Snyd. and Hans. (=*Nectria haematococca* Berk. and Br.), as diagnosed by the Commonwealth Mycological Institute, and Gordon, and has as its imperfect stage *Fusarium solani*. Repeated single-spore cultures made by us of both the ascospores and conidia from the Buxton culture yielded the same, homothallic species. Perithecia developed abundantly within two weeks after transfer and required only diffuse daylight for their initiation and maturation. In these respects we are in agreement with Gordon, and likewise we have not found *F. oxysporum* in the culture, just *F. solani*. These two species are very distinctive and readily differentiated in culture. Over a period of decades during which these two fungus species have been studied, no conclusive evidence has been presented, either of overlapping of the species or of their common *Hypomyces* origin.

Gordon[2] has expressed the opinion that Buxton did not have *F. oxysporum* f. *pisi* but rather *F. solani* f. *pisi* (Jones) Snyd. and Hans., and postulated that the perfect stage in *Hypomyces* (=*Nectria*) which Buxton reported is that of *F. solani* f. *pisi*. Further, that since the perfect stage of this pathogen is unknown, Buxton's report represents the first record of its occurrence.

We do not agree with Gordon's postulation. We have run two separate inoculation tests in the greenhouse on two varieties of pea. In these tests three fungi were used: Buxton's isolate, a similar homothallic *Hypomyces solani* indirectly obtained from the Rothamsted area, England, some ten years ago, and a local isolate of *F. solani* f. *pisi*. Inoculations were made by applying spore suspensions to pea seedlings growing in pots of sterilized soil. In both tests, run at different times, the plants inoculated with Buxton's fungus, the Rothamsted fungus, and the uninoculated controls were completely healthy. Neither cortical root and stem rot nor vascular wilt symptoms were present. Those plants inoculated with *F. solani* f. *pisi*, however, all showed typical brown to blackish lesions completely covering the two inches of underground hypocotyl of each plant.

Our conclusion is that the *Hypomyces* (=*Nectria*) reported by Buxton to be the perfect stage of *F. oxysporum* f. *pisi* is not the perfect stage of this fungus, nor the perfect stage of *F. solani* f. *pisi*. We suggest that this isolate is a homothallic, saprophytic fungus with an imperfect stage in *F. solani*. In our opinion, therefore, no perfect stage is yet known for any clone of *F. oxysporum*, nor for any clone of the pea root and stem rot form, *F. solani* f. *pisi*.

Effect of 6-Methoxybenzoxazolinone on the Growth of *Xanthomonas stewartii* (Erw. Smith) Dowson and its Presence in Sweet Corn (*Zea mays* var. *saccharata* Bailey)

PREVIOUSLY[1] it was reported that 6-methoxybenzoxazolinone (MBOA) inhibited growth of fungi associated with root and stalk rot of field corn. This communication reports the inhibitory effect of MBOA on *Xanthomonas stewartii*, the causal organism of bacterial wilt (Stewart's disease), and the presence of this compound in the sweet corn plant.

The effect of various concentrations of MBOA in agar (beef extract 3 gm., agar 17 gm., distilled water 1,000 ml., adjusted to *p*H 6·0) on the growth of *X. stewartii* after 4 and 8 days is shown in Table 1. Inhibition of growth occurred at 0·15 mgm. per ml.,

Table 1. GROWTH OF *Xanthomonas stewartii* ON AGAR (CHECK) AND ON AGAR CONTAINING MBOA

Concentration of MBOA (per ml. of agar) (mgm.)	Growth Days after inoculation 4	8
0 (check)	+++	+++
0·075	+++	+++
0·15	+	++
0·3	—	+
0·6	—	—

+++, maximum growth; —, no growth.

and the material was bactericidal at 0·6 mgm. per ml.

An ether extract of juice from the roots and stalks of two sweet-corn hybrids, prepared by the method reported earlier[2], significantly inhibited growth of *X. stewartii*. A chemical spot test for the determination of MBOA, in which diatized sulphanilic acid and sodium carbonate mixed with MBOA gives a characteristic reddish spot on filter paper, showed this compound to be present in the extract.

The fact that MBOA inhibits growth of *X. stewartii* and is present in the ether extract of sweet-corn plants suggests that this compound is a possible factor in resistance to bacterial wilt.

Location of Manganese taken up in Short-term Absorption by Oat Roots

The oats (variety Sun II) used in experiments reported here were grown on waxed nylon mesh and supplied with Hoagland and Arnon's[1] culture solution modified by the omission of manganese chloride from the micronutrients. The roots were cut off below the netting when about 3–5 cm. long. They were washed with distilled water and immersed in a large volume of $M/1,000$ manganese sulphate solution for 2 hr.

At the end of this time the excised roots were washed with distilled water and stained by a technique based on that of Batalin[2]. The roots were treated as follows: 10 per cent aqueous potassium hydroxide solution for 5 min., removal of excess liquid by blotting, irrigation with 5 per cent *p*-anisidine solution for 5 min., and finally acidification with dilute sulphuric acid to reveal the presence of manganese by a purple coloration.

This procedure showed that most of the manganese was concentrated in the meristematic zone immediately behind the root cap (dark area in Fig. 1). As the dye is water-soluble such preparations are only temporary.

To exclude the possibility of an artefact caused by differential uptake of the dye, roots similarly prepared were analysed for manganese by the method of Cornfield and Pollard[3]. After absorption of manganese, and washing, the tips (about 2–3 mm.) were cut off, and the two portions sucked dry on a sintered glass filter, weighed and analysed. Manganese contents (as parts per million of fresh weight) are shown in Table 1.

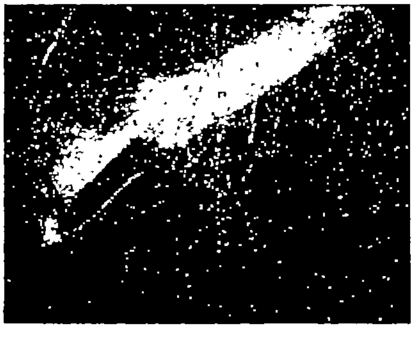

Fig. 1

Table 1

	Manganese absorbed by· Complete excised roots	 Tips and remainder separately
Tips (2–3 mm).	400 p p.m.	260 p.p.m.
Remainder of roots	100 p p m.	130 p p.m.

To test the possibility of translocation within the root to the meristematic region after more dispersed uptake the experiment was repeated, but root tips and the remainder of the roots were separated before being placed in two portions of $M/1,000$ manganese sulphate solution.

These figures are only approximate, since it is not possible, with the technique described, to separate efficiently the meristematic zone from the rest of the root.

Nevertheless the results show sufficiently clearly that: (*a*) short-term uptake of manganese occurs more rapidly in the meristematic region of the oat root; (*b*) translocation of manganese occurs within the root, since when the tips are separated, their uptake is lower, and that of the rest of the root higher, than when uptake occurs in the complete excised root.

It is a pleasure to record thanks to Prof. W. W. Fletcher and other members of the Botany Department of this College for providing microscopic and photographic facilities and other help, and to Dr. Ben-Zion Ginsberg (The Hebrew University, Jerusalem, now on a visit to the University of Edinburgh) for helpful discussion.

Relationship of Radiation, Leaf Area Index and Crop Growth-Rate

Shading experiments, such as those by Blackman and Templeman[1] on white clover, have shown the great reduction in crop growth-rate which occurs when light intensity is curtailed. A second factor influencing crop growth-rate is the leaf area index. There is evidence[2,3] that the rate of dry matter production by a crop or pasture will increase as the leaf area index increases, until a maximum value is attained; thereafter as the index increases further, the rate of dry matter production will decline. This is presumed to occur because the lowermost leaves become so heavily shaded at high leaf area index that their photosynthetic contribution is less than their respiration.

It is likely that these two inter-relationships, light and crop growth-rate, and leaf area index and crop growth-rate, may interact, and various workers, especially Monsi *et al.*[4], have presented theoretical views on this subject.

In the course of competition studies at Adelaide, results have been secured on this inter-relationship between the level of radiation, the leaf area index and the rate of dry matter production. An experiment was conducted to study the influence of shading by grass on the growth of an associate clover when the roots of the two species were kept separate and there was competition only for light. Each species was grown in narrow, slot-like soil compartments; clover swards comprised a number of 'clover slots' placed together, while mixed swards were made up of alternating 'grass slots' and 'clover slots'. The percentage daylight at the surface of the clover canopy was determined by the use of a small selenium cell on a probe[5] and this percentage was applied to the values for total radiation recorded by a nearby Kipp solarimeter. In pure cultures of clover the surface light intensity was the full daylight; in the mixed cultures of grass and clover the light intensity at the surface of the clover was derived from the profile of the light intensity (based on readings at 2 cm. vertical intervals) and a measurement of the mean height of the upper clover leaves. Frequent harvests permitted calculation of the growth-rate of the clover during successive 14-day intervals. The experiments were done in the winter period June–August 1959; the weekly mean temperatures during these months showed unusually low variation (54·3° F. ± 2·7° F.).

The results of this work indicate that for any level of radiation there is an optimum leaf area index, at which crop growth-rate will be maximal, and that the value of the optimum index increases as radiation rises. These concepts are presented in Fig. 1 in which isopleths for crop growth-rate are drawn for varying levels of radiation and leaf area index. With a radiation of 50 gm.cal./cm.^{2}/day the optimum leaf area index would be about 3·5, and the crop growth-rate low (0·07 gm./dm.^{2}/day), whereas with a radiation of 150 gm.cal./cm.^{2}/day the optimum leaf area index would be about 5, and the crop growth-rate relatively high (>0·1 gm./dm.^{2}/day). The broken line indicates the rates of production when varying levels of radiation are associated with optimum values of leaf area index. To the left of this broken line, light interception is incomplete; to the right of the line, some of the lower leaves are below compensation point.

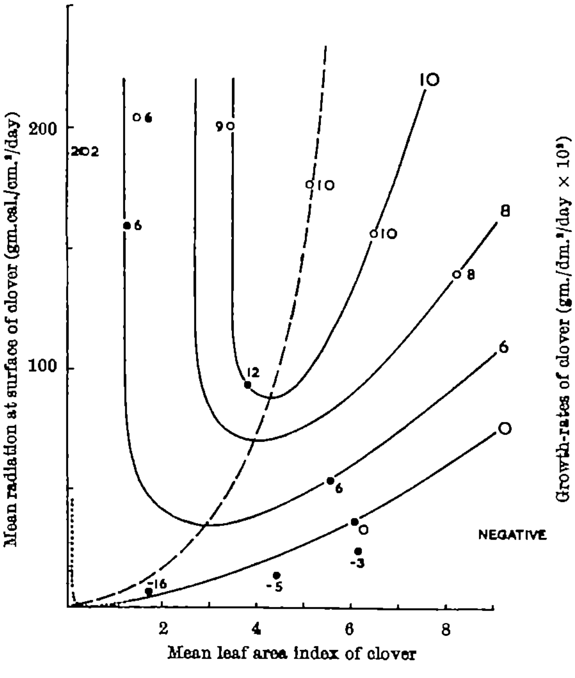

Fig. 1. ○, In pure stands; ●, in mixed stands

When shading of the clover by grass was severe, the entire clover community was below compensation point and negative values for growth-rate were recorded. The zero isopleth for crop growth-rate shows the level of radiation needed to keep a clover sward of any particular leaf area index at compensation point. It is suggested that extrapolation of this line to the lowest index values would follow the course shown by the dots—that is, it would turn sharply at the minimum index required to maintain plants alive. The part of the graph in which the isopleths are vertical and parallel is the zone in which an increase in radiation would give no further increase in growth-rate of a sward of any particular leaf area index.

The data are not sufficient to establish these relationships with precision but it suggested that they indicate the nature of the interactions in pasture swards and presumably also in crops and other plant communities.

Possibility of Fixation of Atmospheric Nitrogen by the Rice Plant

A RECENT communication[1] by Chakraborty and Sen Gupta suggested that rice plants might be capable of fixing atmospheric nitrogen. We have made an attempt to confirm their result using the variety 'Lead 35' (a pure-line selection of material derived from British Guiana). No evidence of nitrogen-fixation has been obtained.

Chakraborty and Sen Gupta found that the maximum rate of nitrogen-fixation occurred in young plants—a gain of 50 per cent of the nitrogen content of 7-week-old plants being recorded after a further month in nitrogen-free medium. The percentage gain in older plants was substantially lower. For this reason our experiments have been carried out on young plants.

Rice plants were grown from seed in trays. Each tray of 30 seedlings contained 2 l. of nutrient medium of the following composition, changed at fortnightly intervals:

$MgSO_4.7H_2O$	0·35 gm./l.
$Ca(NO_3)_2$	0·92 ,,
KH_2PO_4	0·38 ,,
KNO_3	0·85 ,,
Ferric ethylenediamine tetraacetic acid	0·07 ,,
H_3BO_3	1·86 mgm./l.
$ZnSO_4.7H_2O$	0·29 ,,
$MnSO_4.4H_2O$	2·23 ,,
$(NH_4)_6Mo_7O_{24}$	0·035 ,,
*p*H	about 4·5

The whole apparatus was enclosed in a polythene cloche to prevent contamination of plants or medium by rain-water, dust and insects. Plants were grown for an initial period in complete medium, then removed and their fresh weights determined. After washing in three changes of distilled water, one batch was analysed by the micro-Kjeldahl method and the remainder were returned to the dishes to be grown for a further period, this time in a nitrogen-deficient medium similar to that used in the first period but with the omission or substitution of nitrogenous constituents. At the end of the second period, these plants were removed and analysed together with their dead leaves, which had been collected and preserved during the period of nitrogen starvation. The results were assessed by plotting fresh weight at the beginning of the period of nitrogen starvation against the Kjeldahl-nitrogen content before and after nitrogen starvation. Regression lines were then calculated for nitrogen content on fresh weight for each set of plants.

In the first experiment, 68 plants were grown, 44 analysed after the first three weeks and 24 after a further three-week period of nitrogen starvation. The equation for the regression line after the initial period was $y = 5{\cdot}49x - 0{\cdot}11$ ($r = 0{\cdot}976$), and after the period of nitrogen starvation $y = 6{\cdot}19x - 0{\cdot}52$ ($r = 0{\cdot}914$). Statistical comparison of these lines showed that there was no significant difference between their slopes and that no significant increase in the nitrogen content of the second batch had occurred. This was to be expected as marked deficiency symptoms had become apparent in the plants after they had been in the nitrogen-deficient medium for a week: leaves became chlorotic and eventually died from the tips. However, as heavier plants in this experiment had shown a tendency towards apparent gain in nitrogen content, a second experiment was carried out in which the initial period was increased to 4½ weeks. 52 plants were grown, of which 29 were analysed after the first period and 23 after nitrogen starvation. The results are shown in Fig. 1. The nitrogen contents of the starved plants were significantly higher than would be predicted from the first regression line. The apparent gain amounted to 17·7 per cent of the average initial nitrogen content per unit weight of fresh plant material. As the plants had again shown severe deficiency symptoms after a period of one week of nitrogen starvation, it was considered that an alternative explanation to that of nitrogen-fixation was likely. An attempt was made to determine the nitrate content of similar plants to discover whether nitrate reserves—not measurable by the ordinary micro-Kjeldahl method—were being used up during the period of nitrogen starvation and rendered amenable to determination by the Kjeldahl method, resulting in an increase in the measured nitrogen content of the plant.

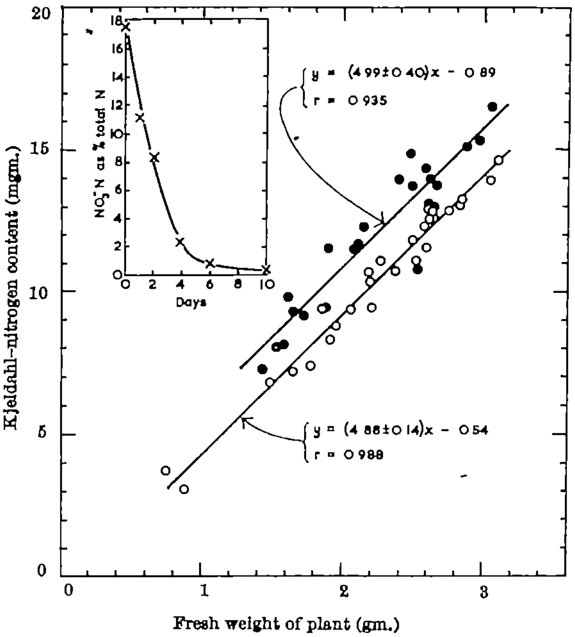

Fig. 1. Relationship between fresh weight of plants 4½ weeks old at the beginning of the period of nitrogen starvation and the Kjeldahl-nitrogen content before (○) and after (●) 3 weeks of nitrogen starvation. Inset: Depletion of nitrate in 4-weeks-old plants transferred to nitrogen-deficient medium

Rice plants were grown as before for an initial period of 4 weeks. Analysis of 9 plants by the original micro-Kjeldahl method gave nitrogen contents comparable with previous results. Six plants from the same batch were dried at 105° C., extracted for 1 hr. with boiling water, and the extract distilled using magnesium oxide and Devarda's alloy for the determination of ammonium nitrogen. The content of nitrate nitrogen was found to be 17·5 per cent of the total nitrogen content of the plant. This figure is in agreement with the apparent gain in the previous experiment. We have found that the nitrate content of older plants is less: for example, 7-week-old plants contained 10·7 per cent of their nitrogen as nitrate. Reliance on ordinary Kjeldahl-nitrogen determinations would therefore result in an apparent decrease in 'fixation' in older plants. But we have also found that the nitrate content of plants grown in hydroponics is abnormally high when compared with rice plants growing under natural conditions: using the same analytical method, measurable quantities of nitrate nitrogen could not be detected in rice plants growing under field conditions, even when plants were sampled at daybreak from plots which had received heavy dressings of nitrogenous fertilizer.

Fifteen of the 4-week-old plants were also transferred to the nitrogen-deficient medium from which they were afterwards removed at intervals and their nitrate content determined. The results are shown in the inset to Fig. 1. Severe symptoms of nitrogen deficiency were apparent after 7 days. At this stage the nitrate reserves of the plants were almost exhausted.

The results demonstrate that caution is necessary when applying the ordinary Kjeldahl methods to plants grown in hydroponics because of the unexpectedly high nitrate contents which may be found in such plants.

ENTOMOLOGY

Enzymic Glucoside Synthesis in Locusts

INSECTS are known to convert foreign phenols to glucosides[1], and a few normally occurring glucosides have been identified in insects[2-4]. In other organisms the sugar for analogous glycoside synthesis comes from uridine diphosphate sugar derivatives and a similar process appears to function in insects the uridine diphosphate glucose (UDPG) of which provides the glucose for trehalose[5] and arbutin[6] formation. We have now investigated the distribution and extent of this mechanism and the specificity of its need for UDPG in the locust, *Schistocerca gregaria*.

The aglycone used as substrate was 4-methylumbelliferone, which forms fluorescent glycosides which may be hydrolysed by snail gastric enzyme or acid to the highly fluorescent phenol. Samples of reaction mixtures were chromatographed on No. 4 Whatman paper in 2-butanone/2 *N* ammonia (1 : 1, v/v) to separate the glucoside (R_F 0·6) from unchanged aglycone (R_F 0·8). The glucoside zone, located by examination under ultra-violet light, was eluted with *N* hydrochloric acid and estimated by measurement of its fluorescence at 410 mμ when activated at 320 mμ in an Aminco-Bowman spectrophotofluorimeter.

When separate tissues of fifth instar hoppers or adult locusts were examined, little conjugating activity was found in organs other than the fat body (Table 1). Measurements were also made of the conjugating capacity of whole locust carcasses after removal of the gut and Malpighian tubes. Locusts obtained on different occasions varied widely in their capacity but rates of formation of glucoside up to 250 μgm./hr./locust were found. For these experiments the carcasses were suspended in 5 ml. of saline[7] containing 0·5 mgm./ml. of methylumbelliferone and 0·1 ml. aliquots removed periodically for analysis. The concentration of glucoside increased linearly with time for at least 2 hr. and no difference in rate was observed with air or oxygen in the gaseous phase. The saline solution used contained 0·8 per cent (w/v) of glucose but omission of the sugar or replacement with equimolar amounts of trehalose or sucrose made no significant difference in the rate of glucoside synthesis.

Table 1. DISTRIBUTION OF GLUCOSIDE-FORMING ACTIVITY IN LOCUSTS

Organ	Methylumbelliferone conjugated with glucose (μgm./hr./locust)
Washed foreguts	0·05
Washed gastric cecæ	0·06
Washed mid- and hind-guts	0·03
Malpighian tubules	0
Fat bodies	2·0
Flight muscles	0
Hæmolymph	0

Each tube contained 0·1 mgm. 4-methylumbelliferone dissolved in 0·2 ml. grasshopper saline (ref. 7) at *p*H 7 and the tissues from 5th instar hoppers. Tubes were incubated at 37° for 1 hr. in air.

When fat bodies were homogenized for 5–10 sec. in a glass Potter homogenizer, the conjugating activity was reduced to very low levels but this could be restored to normal by addition of UDPG to the medium (Table 2).

Table 2. EFFECT OF HOMOGENIZATION AND UDPG ON METHYL UMBELLIFERONE GLUCOSIDE SYNTHESIS IN LOCUST FAT BODY

Experiment	Rate of glucoside formation (μgm./hr./locust)
1. Fat body suspension (3 fat bodies/ml.)	10·4
2. Fat body suspension after homogenizing	0·9
3. Fat body suspension after homogenizing and addition of UDPG 1 mgm./ml.	12·9

Fat bodies were suspended by shaking in saline and 1 ml. suspension used for experiment 1. The rest of the suspension was homogenized and 1 ml. of homogenate used for experiments 2 and 3. 4-Methylumbelliferone was added to each tube to give a concentration of 0·5 mgm./ml.

Homogenized fat bodies were centrifuged at 500–1,000 r.p.m. and the aqueous layer used as enzyme in determination of optimum substrate concentration and *p*H. The reaction showed a broad *p*H maximum at 7–8 and at this *p*H and with a methylumbelliferone concentration of 0·5 μgm./ml. the maximum rate of reaction was found with 1 mgm./ml. of UDPG.

Uridine diphosphate N-acetylglucosamine, which may be involved in chitin formation, was substituted for UDPG in similar experiments but no evidence was found of any glucosaminide formation. Similarly, UDPGA (uridine diphosphate glucuronic acid), which is used in analogous vertebrate detoxication reactions, gave no glucuronide when incubated with methylumbelliferone and intact or homogenized locust carcasses or fat bodies. In experiments where 0·1–1·0 equivalents of UDPGA were added to reaction mixtures containing the optimum concentration of UDPG, no inhibition of glucoside formation was observed.

This work was supported by grants from the Anti-Locust Research Centre.

Fate of Aldrin and Dieldrin in Locusts

ALDRIN and dieldrin are widely used as insecticides, and dieldrin has been employed against locust hopper bands in the field. Aldrin is known to be epoxidized to dieldrin in insects[1,2], in vertebrates[3], in soils[4] and on plants[5]; but in many cases analytical difficulties have left the extent of the change not clear. The availability of aldrin and dieldrin labelled with chlorine-36 has now allowed us to examine quantitatively the metabolism and excretion of aldrin and dieldrin in *Schistocerca gregaria*.

Fifth instar hoppers were injected abdominally with an olive oil solution of the insecticides (2 μgm./5 μl.; about 100 c.p.m.) and kept at room temperature. Any insects surviving after seven days were added to the dead, which had been preserved under

Table 1. EXCRETION OF ALDRIN AND DIELDRIN BY LOCUSTS

Material used	Percentage of dose excreted	Percentage of chlorine-36 in bodies as: aldrin	dieldrin	water-soluble material	Percentage of chlorine-36 in excreta as: aldrin	dieldrin	water-soluble material*
Aldrin 1	3·3	62	39	0	44	52	5
2	21	67	36	0	57	41	3
3	—	—	42	—	—	—	—
Dieldrin 1	22	0	101	0	—	—	—
2	—	—	—	—	—	99	0
3	21	0	101	0	—	108	0

2 μgm. was injected in olive oil solution and surviving insects killed after 7 days.
* Not chloride.

ethanol. Excreta from each batch of locusts were collected at the end of seven days and similarly preserved under ethanol. Dosing of batches of locusts was repeated weekly until a total of 40,000 c.p.m. had been injected.

Excreta or bodies were homogenized in the Atomix blender with ethanol and filtered. The residue was then extracted in turn with acetone, 2 *N* ammonia and 0·1 *N* hydrochloric acid and the pooled filtrates concentrated *in vacuo* and counted as 'infinitely thin' layers on aluminium planchettes with a thin end-window counter. The extraction procedure was repeated until all the injected activity had been recovered.

The pasty residue left on concentration of the extracts was partitioned between water and benzene, and any water-soluble material removed and counted after concentration. Aliquots of the benzene solution were taken for dilution analysis with aldrin or dieldrin.

Aldrin was re-isolated from the mixture and crystallized to constant specific activity. Its radioactive purity was checked by conversion to the 2,4-dinitrobenzene sulphenyl derivative, m.p. 264°, with the same equivalent specific activity. Dieldrin was re-isolated, and its radioactive purity confirmed by conversion to the antimony chloride complex, which had the same equivalent specific activity.

This derivative was prepared by mixing equivalent amounts of dieldrin and antimony trichloride in hot *n*-hexane solution, from which the complex crystallized on cooling. It formed colourless needles from hexane, m.p. 122°, but decomposed in polar solvents. Found: Sb 19·6, Cl^- 17·5, $C_{12}H_8Cl_6O \cdot SbCl_3$; required Sb 20·0, Cl^- 17·5 per cent. Antimony tribromide formed a similar complex, m.p. 131°. Found: Sb 16·4, Br^- 32·7, $C_{12}H_8Cl_6O \cdot SbBr_3$; required Sb 16·4, Br^- 32·3. Endrin also formed similar complexes but aldrin and isodrin gave no derivative under these conditions.

Aldrin and dieldrin were only slowly excreted by locusts (Table 1) and the rate of oxidation of aldrin (Table 2) was considerably lower than has been reported for flies (about 0·1 μgm./hr./fly) under similar conditions[1]. A small amount of water-soluble material was found in excreta but could not be detected in the bodies in spite of the much larger amounts of radioactive material there. This was shown not to be chloride by dilution analysis and is being further investigated.

Dieldrin itself was not further metabolized and was slowly excreted unchanged.

Repeated sub-lethal doses of dieldrin, in contrast to di-nitro-*o*-cresol[6], should therefore act cumulatively in locusts as has been found with flies[7].

We are grateful to Prof. R. T. Williams for a gift of the radioactive insecticides used in this work.

Table 2. OXIDATION OF ALDRIN TO DIELDRIN IN LOCUSTS

No. of locusts	Dose (μgm./locust)	Time after dosing (hr.)	Dieldrin formed (percentage of dose)	Rate of oxidation (μgm./dieldrin/locust/hr.)
12	1·8	44	22·7	0·011
12	1·8	60	89·1	0·012
12	1·8	72	42·0	0·011
29	1·8	(pooled dead)	42·2	—
7	0·9	98	54·0	0·005

5th instar locusts were injected with aldrin in olive oil and groups of 12 analysed for dieldrin at intervals. Insects dying at any time were pooled and analysed for dieldrin. No food was given and excreta were negligible.

The work was supported by grants from the Anti-Locust Research Centre.

BACTERIOLOGY

Lipolytic Activity of Some Anaerobic Bacteria

THE use of the water-soluble 'Tweens' for easy detection of lipolytic activity by micro-organisms has already been described by me[1]. This technique has now been adapted to detect lipolytic activity of anaerobic bacteria. The best results were obtained by using the medium '*VF*' of Prévot with the addition of 'Tween 20', '40', '60', or '80' (polyoxyethylene sorbitan mono-laurate, mono-palmitate, mono-stearate and mono-oleate respectively) in a final concentration of 7 × 10^{-3} *M* plus 0·01 per cent (w/v) calcium chloride. After incubation at 37° C. the 'Tween' cultures were examined for the presence of opaque haloes, due to the formation of conspicuous precipitates of calcium laurate, palmitate, stearate or oleate around the zones of growth. The test was made either in tubes (8 mm. × 180 mm.) following the classical techniques for growing anaerobic bacteria,

or on plates in Brewer's jars. Simultaneously, lipolytic activity was tested by the Eijkman[2] method using the Prévot medium.

Table 1 shows that, of the twenty-eight strains tested, twenty-two had lipolytic activity. Although four of the lipolytic species did not exhibit any specificity, hydrolysing all four 'Tweens', eleven strains were able to hydrolyse only two or three of the four 'Tweens' tested. Four strains show a higher substrate specificity hydrolysing only one of the four 'Tweens'. Another striking feature of the 'Tween' test is its greater sensitivity than the Eijkman test. Seven strains which were non-lipolytic on the Eijkman plates were able to hydrolyse 'Tweens'.

These results may indicate that we are dealing with adaptive lipases which, however, cannot be detected with the Eijkman test (cf. ref. 1). Further investigations are being made to elucidate the specificity and mechanism of adaptation of these enzymes.

Greater Susceptibility to *Mycobacterium johnei* of *C.57* Black Mice, when compared with *CBA* and Swiss White Mice

RESEARCH on Johne's disease, a fatal enteritis of cattle and sheep due to infection with *Mycobacterium johnei*, has long been hampered by the lack of a suitable laboratory animal as an experimental host. In more recent years, Francis[1] and Lominski, Cameron and Roberts[2] have described the experimental infection of white mice; Ford[3], however, failed to demonstrate intestinal lesions in the latter species and I have obtained intestinal lesions in only a minority of inoculated Swiss white mice (unpublished work). It was decided to compare the susceptibility of two further strains of mice with that of the Swiss white strain.

Equal numbers of *C.*57 black mice, *CBA* brindle mice (the foundation mice of both these stocks were obtained from the Medical Research Council Radiobiological Unit, Harwell, by courtesy of Dr. M. F. Lyon) and Swiss white mice (from stock maintained at this Station for several years) were inoculated intraperitoneally with 2 mgm. of moist *M. johnei* in suspension in saline; this strain of *M. johnei* was originally isolated from a case of the disease in a cow and was cultured on Taylor's medium[4].

Three months after infection, 15 mice of each strain were killed, and *M. johnei* infection of the intestines was detected, by histological methods, in two of the *C.*57 mice and one of the Swiss white mice.

Six months after infection, six mice of each strain were killed; intestinal infection was detected in all six of the *C.*57 mice and in three of the white mice, but not in the *CBA* mice.

Nine months after infection, six mice of each strain were killed. The small intestines of all six of the *C.*57 mice were visibly enlarged, due to thickening of the mucosa; histological and smear examinations of the intestines confirmed the presence of *M. johnei* in the six *C.*57 mice and in one of the six white mice, but in none of the *CBA* mice.

One year after infection, six mice of each strain were killed; the intestines of all six *C.*57 mice, and two of the six white mice, were visibly thickened. *M. johnei* infection of the intestines was detected in the six *C.*57 mice, in one white mouse and in one *CBA* mouse.

These results indicate that the three strains of mice differ in their susceptibility to intestinal infection with *M. johnei*. The susceptibility of the *C*.57 black mice was markedly higher than that of the other strains.

A full report of this experiment will be published elsewhere. Further experiments are in progress to ascertain the suitability of the *C*.57 black mouse as a laboratory animal for work on Johne's disease.

The Host-Range of a *Streptomyces aureofaciens* Actinophage

A VIRULENT actinophage destructive to *S. aureofaciens* cultures and chlortetracycline (the trade mark of American Cyanamid Company for chlortetracycline is 'Aureomycin') fermentations had previously been reported[1]. Limited data regarding its host-range obtained at that time showed that it was a monovalent phage. Since other actinophages have been noted to be either polyvalent or monovalent[2], further tests have been made with the *S. aureofaciens* phage to establish more clearly the nature of its host-range.

Evidence is presented in this communication confirming that this phage is species-specific for *S. aureofaciens*. Tests for susceptibility to *S. aureofaciens* phage were made by spreading *Streptomyces* spore suspensions over the surface of corn-steep agar, resulting in confluent growth surfaces within 24–36 hr. When the spore suspensions had dried, the seeded surfaces were spotted with drops (0·01–0·02 ml.) of phage suspension using two concentrations in broth, 3×10^9 and 3×10^8 phage particles per ml. Controls consisted of broth and water drops spotted on the seeded surfaces. Observations for the presence of plaques were made after 1, 2, and 4–5 days. All tests were made at least in duplicate; in the case of a doubtful reaction, tests were repeated.

Representatives of forty diverse named species of *Streptomyces* other than *S. aureofaciens*, selected to encompass most sections and series of the genus as set up by Pridham *et al.*[3], showed no reaction to the phage. Tests were made with 3–5 strains each of *S. griseus*, *S. lavendulae*, *S. fradiae*, *S. antibioticus*, *S. rimosus*, *S. hygroscopicus*, *S. purpurascens*, *S. albogriseolus*, *S. tanashiensis* and *S. erythreus* and with one strain each of 30 additional species, use being made wherever possible of authentic strains from type culture collections.

Twenty-five soil isolates determined to be *S. aureofaciens* on the basis of morphological, cultural and physiological characteristics were also used in this work. Eighteen of these isolates were susceptible to the virulent *S. aureofaciens* phage, though some less than others, as indicated by reduced plating efficiency. The seven resistant isolates gave indications that their resistance was connected with the presence of homologous temperate phage(s) in their cultures. It is not definitely known whether these cultures are lysogenic or carry phage. Results with the *S. aureofaciens* group of isolates are recorded in Table 1.

† Phage susceptibility (as indicated by plating efficiency): +++, high; ++, intermediate; +, low; ±, very low (a few plaques observed); −, none (no plaques observed).

The possible utility of actinophage susceptibility as a criterion for species differentiation in the genus *Streptomyces* has been the subject of much discussion among investigators concerned with the taxonomy of this group. It seems to be generally agreed that polyvalent phages would be difficult to utilize because of their complex host relationships, but that species-specific, monovalent phages would have definite applicability, in conjunction with other taxonomic features characterizing *Streptomyces* species[2,4,5]. Susceptibility of newly isolated *Streptomyces* cultures to such a species-specific phage would reinforce other results on their close relationship to the phages' host species. Lack of susceptibility, however, would not exclude an isolate from being allied with the host species, as species susceptible to phages are generally known to comprise strains resistant to the same phages.

In the light of this evidence that the subject *S. aureofaciens* actinophage is species-specific, it was extremely interesting from a taxonomic point of view to extend this investigation to include three controversial organisms, *S. viridifaciens*[6], *S. psammoticus* (*S. feofaciens*)[7] and *S. sayamaensis*[8]. Although described as separate new species by those who isolated them, these organisms have morphological, cultural and physiological properties which raise serious doubts as to their distinction from *S. aureofaciens*. The results obtained, all three proving to be susceptible to the virulent, monovalent *S. aureofaciens* phage, add support to the contention that these three species should be reduced to synonymy with *S. aureofaciens*.

GENETICS

Morphological Separation of Cytological Races in *Ranunculus ficaria* L.

THE presence of axillary tubercles ('bulbils') in the various races of *Ranunculus ficaria* L. *sensu lato* is still a matter of some debate. So far as British material is concerned, previous workers have shown that all tubercle-bearing plants investigated cytologically have been tetraploid, with $2n = 32$, while non-tubercle-bearing plants have been diploid ($2n = 16$). Marsden-Jones[1] proposed separating the tubercle-bearing plants as var. *bulbifera*, as opposed to typical non-tubercle-bearing plants which were later described by Clapham[2] as var. *fertilis*. The two races were later raised to sub-specific rank by Lawalrée[3].

Other differences between the two races given by Marsden-Jones were: number and relative width of the petals, range in stamen and carpel number, proportion of viable pollen and viable seed set. This range of variation in stamens and carpels is such, however, that they do not form useful characters for taxonomic separation.

Presence or absence of bulbils has always been considered a distinguishing character for the two races. However, it has not always been realized that the tubercles are only produced towards the end of the flowering season and this in itself has caused some confusion: presence of tubercles is a positive character while absence may imply true absence or simply young material which will later develop tubercles. Almost equal reliance has been placed on the suggested floral differences for taxonomic distinction, notably petal number and degree of overlap, particularly in the absence of tubercles. These differences have been widely accepted and never, as far as we are aware, disputed.

Field and laboratory studies on local populations in north Wales and Cheshire during the past few years have pointed to the unreliability of these floral characters as a means of distinguishing the two cytological races. In some populations the characters given by Marsden-Jones hold good but it is not uncommon to find them completely reversed in other populations. This is specially true of the petal characters. Thus while it is possible to separate populations in the same locality into morphologically different types, agreeing with the diploid and tetraploid races suggested by Marsden-Jones, actual cytological investigation has shown that some apparent tetraploids have proved to be diploids and vice versa.

In Table 1 details are given of the floral characters and cytological status of a selection of the populations studied in north Wales and Cheshire. Measurements were made of samples of 100 plants in each population. The following points may be noted.

Petal range. Although the mean petal number has usually been found to differ between diploid and tetraploid populations, the position of the mean is not correlated overall with the level of ploidy (for example, Nos. 5906, 5915 in Table 1); similarly, although there appears to be a difference in petal range this is not constant and in any event the overlap between the two makes it an unreliable character.

Petal type. Two types of petal are commonly recognized: broad and overlapping in the diploid and narrow, not overlapping, in the tetraploid. In practice we have found an intermediate to occur so frequently that it became necessary to recognize a third type. This intermediate type has been found in both races. Apart from this, the broad-type petal has been found in tetraploids and the narrow in diploids, contrary to what is normally stated (Nos. 5906, 6001). Consequently, no reliance can be placed on petal type as a diagnostic character.

Table 1

Reference No.	Character						
	Axillary tubercles + or −	No. of stamens	No. of carpels	No. of petals	Petal type	Chromosome number $n =$	Habitat
5903	−	27–35	25–44	(7–)8(–11)	1	8	Hedgerow
5904	−	19–37	22–31	8(–10)	2	8	Hedgerow
5906	−	50–60	45–50	9–11	3	8	Woodland
5907	+	30	30	.	1	16	Hedgerow
5908	−	24–43	26–45	8(–9)	2	8	Roadside
5909	−	23–30	14–37	(7–)8(–9)	1	8	Roadside
5910	−	30	30	8	1	8	Woodland
5912	+	35	30	.	3	16	Woodland, riverside
5915	+	20	12–19	7–8	2	16	Riverside
5916	−	17–40	13–30	8 (–10)	2	8	Woodland
5917	+	23–30	23–30	7–8	3	16	Woodland
6001	+	22–32	7–26	8–10	1	16	Woodland
6002	−	23–29	13–23	8	3	8	Woodland

+ or − is presence or absence of axillary tubercles. Petal type: 1, broad, overlapping; 2, intermediate; 3, narrow, not overlapping.

The conclusions that may be drawn from the above data are that in the absence of axillary tubercles, in young material, petal type is not a reliable cytological marker since it is not constantly correlated with level of ploidy. Furthermore, it is not entirely certain that the association of tubercles with the tetraploid is always constant, although it would generally appear to hold good. It may be possible to separate the diploids and tetraploids by other characters associated with the frequency and position of the flower buds in the inflorescence, but in any event it is quite clear that the recognition of the different cytological races by morphological characters is by no means so simple as is usually believed, if indeed it is consistently possible at all. It should be emphasized that these studies have been made on populations from only a small part of the range of the species and they are being extended to other areas. Details of the present and other investigations will be published separately.

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. A. Robinson: "Bird Watching in the Medway Valley".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Chemical Research Assistant/Technician (preferably with experience of steroid chemistry) to work with a team investigating aspects of chemical endocrinology in relation to human biology and genetics—Dr. J. M. Tanner, Institute of Child Health, Great Ormond Street, London, W.C.1 (February 23).

Assistant Lecturer or Lecturer in Physics—The Registrar, The University, Sheffield (February 25).

Assistant Lecturer or Lecturer (with a special interest in physiology) in Botany—The Secretary, The University, Exeter (February 25).

Junior Lecturer (preferably with interests in the fields of either (*a*) soils and climate or (*b*) regional geography) in Geography—The Registrar, Trinity College, Dublin, Republic of Ireland (February 27).

Research Student (with experience in one of the following fields medicine, chemistry, biochemistry, or pharmacology) in Pharmacology, for work on naturally occurring neuro-muscular blocking agents—The Registrar, Trinity College, Dublin, Republic of Ireland (February 27)

Assistant Lecturer (with a good honours degree with special interests in mineralogy) in Geology—The Registrar, King's College (University of London), Strand, London, W.C.2 (February 28).

Lecturer or Assistant Lecturer in the Department of Mathematics, Makerere College, The University College of East

Africa—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (February 28).

UNIVERSITY LIBRARIAN—The Secretary and Registrar, The University, Southampton (February 28).

PLANT PHYSIOLOGIST (with a good honours degree in botany and research experience) for investigations of effects of temperature, oxygen and carbon dioxide on the respiration of fruit—The Director, Ditton Laboratory, A.R.C., Larkfield, Maidstone, Kent (March 1).

RESEARCH ASSISTANT to operate and maintain the electron microscope and ancillary equipment in the Metal Physics Section of the Cavendish Laboratory—The Secretary of the Department of Physics, Cavendish Laboratory, The University, Free School Lane, Cambridge (March 1).

EDUCATION PSYCHOLOGIST, Grade I (man or woman)—The Director of Education, Shire Hall, Durham (March 3).

LECTURER (with a good honours degree, teaching experience up to degree level, and research experience) IN ZOOLOGY at the Nigerian College of Arts, Science and Technology, Zaria Branch—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (March 3).

LECTURER (preferably with a special interest in microwaves and microwave devices, both vacuum and solid state) IN APPLIED PHYSICS—The Secretary, The University, 38 North Bailey, Durham (March 4).

RESEARCH ASSISTANT (British nationality) IN THE WHEATSTONE LABORATORY for research on cathodoluminescence, scintillation properties, etc., of certain elementary crystals—Prof. F. C. Champion, Department of Physics, King's College (University of London), Strand, W.C.2 (March 5).

LIBRARIAN at the University College (Fourah Bay College), Sierra Leone—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 6).

HELMINTHOLOGIST, SCIENTIFIC ASSISTANT (with a degree and experience in helminthology) to prepare abstracts and assist in editorial work on *Helminthological Abstracts*—The Acting Director, Commonwealth Bureau of Helminthology, The White House, 103 St. Peter's Street, St. Albans, Herts (March 11).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS IN BIOCHEMISTRY, CHEMISTRY, CHEMICAL OCEANOGRAPHY, ENGINEERING and PHYSICS—The Registrar, The University, Southampton (March 11).

LECTURER IN PHYSICAL and/or INORGANIC CHEMISTRY in St. Salvator's College, St. Andrews—Joint Clerk to the University Court, The University, St. Andrews (March 11).

OFFICIAL FELLOW and LECTURER IN PHYSIOLOGY; and a DEMONSTRATOR IN PHYSIOLOGY—The Warden, New College, Oxford (March 11).

UNIVERSITY DEMONSTRATOR IN PHYSIOLOGY—The Administrator, Department of Physiology, The University, South Parks Road, Oxford (March 11).

ASSISTANT LECTURER or LECTURER IN THE DEPARTMENT OF PURE MATHEMATICS—The Registrar, University College of Wales, Aberystwyth (March 13).

LECTURER or ASSISTANT LECTURER IN PSYCHOLOGY—The Registrar (Room 22, O.R.B.), The University, Reading (March 18).

LECTURER IN GEOGRAPHY at Rhodes University, Port Elizabeth, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, March 20).

READER IN INORGANIC CHEMISTRY at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 20).

SENIOR LECTURER IN HORTICULTURE at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, March 25).

SENIOR LECTURER IN PHYSICS at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, April 28).

FERRANTI FELLOW (with at least two years research experience) IN COMPUTING, to do original work in any field connected with computation or other application of digital computers, with access to a Ferranti Mercury—The Director, University Computing Laboratory, 9 South Parks Road, Oxford (July 31).

DEMONSTRATOR IN AGRICULTURAL BOTANY; and a DEMONSTRATOR IN AGRICULTURAL ZOOLOGY at the School of Agriculture, Sutton Bonington—The Registrar, The University, Nottingham.

JUNIOR RESEARCH FELLOW IN CHEMISTRY—The College Secretary, Balliol College, Oxford.

LECTURER (preferably with industrial experience such as in nuclear fuel processing) IN CHEMICAL ENGINEERING for the Nuclear Technology Group—G. R. Hall, Department of Chemical Engineering and Chemical Technology, Imperial College of Science and Technology, London, S.W.7.

LECTURER (with a good medical qualification and some laboratory experience) IN THE DEPARTMENT OF BACTERIOLOGY AND IMMUNOLOGY—The Dean, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1.

TECHNICIAN (female) IN THE PHYSICS LABORATORY, for work concerned chiefly with diagnosis and treatment using radioactive isotopes—The Hospital Secretary, Dudley Road Hospital, Birmingham, 18.

SCIENTIFIC AND TECHNICAL RESOURCES OF BRITISH RAILWAYS

THE debate on British Railways in the House of Commons on October 26, which was opened by the Minister of Transport, Mr. E. Marples, and that in the House of Lords on problems of transportation on December 7, were both prompted essentially by the annual report and accounts of the British Transport Commission for the year ended December 1, 1959, and by the report from the Select Committee on Nationalized Industries dealing with British Railways*. The latter report is of considerable scientific interest, particularly those sections dealing with technical resources, design and research and with man-power and productivity. It includes a memorandum by the British Transport Commission on research and other memoranda on man-power, productivity and training and on qualified scientists and engineers—memoranda which are of greater interest in view of the observations on research and development in the chapters which Prof. W. A. Robson devotes to those subjects in his recent book on *Nationalized Industry and Public Ownership*.

Some of the realism was taken out of both debates by Mr. Marples's announcement at the start that the Government was also considering the recommendations of a Special Advisory Group under Sir Ivan Stedeford, which is supplementing the work of the Select Committee, and that it intended to place its proposals before the House as soon as possible in the form of a comprehensive paper. Nevertheless, this can scarcely explain the absence of reference to these vital aspects of the railway services in both debates The Minister for Science made no reference to research or to scientific or technical staff in replying on the debate on December 7, although he agreed to the need for an efficient and modernized railway system as far ahead as could be seen. Only by Mr. Austen Albu was any real emphasis placed on these factors or indeed any reference made.

Mr. Albu, himself a member of the Select Committee, asserted that modern industry needs a scientific spirit throughout its whole organization and not only among its technical staff; he suggested the appointment as general managers on the Railways of one or two engineers with a modern university background. Meanwhile, he thought the Transport Commission should consider how to achieve greater co-ordination between the various branches of its engineering staff. He pointed out that the railway systems of the world, including the British railway system, have never done much research, and that the Transport Commission is only now beginning to build up a proper research staff. Although the industry is undergoing rapid technological change, only 0·3 per cent of its employees are qualified scientists or engineers; between 1956 and 1959 the number of professionally qualified engineers decreased from 598 to 484. In 1959 only 277 qualified electrical engineers were employed, and 512 graduate scientists and engineers. Witnesses before the Select Committee showed no awareness at all of the level of professional staff required to deal with the revolutionary changes in progress.

Mr. Albu's alarm at this position, his concern at the relatively low level of salaries offered to engineers by the Transport Commission, and his assertion that the Commission has not begun to understand the revolution in education in Britain since the end of the War, was endorsed by Sir Toby Low, chairman of the Select Committee; but his points were not developed further in the debate, which was concerned excessively with political issues, nor were they considered by Mr. John Hay, Joint Parliamentary Secretary to the Ministry of Transport, in replying on the debate. Prof. Robson devoted some attention to research in nationalized industry generally in his book, but was concerned chiefly with the organization of research both within such industries and within the Government; and while agreeing to the need for research in these industries, he gave no indication that he had modified the opinion expressed earlier in *Problems of Nationalized Industry*, that Britain should not rely excessively on these industries to conduct more fundamental scientific research.

Since that opinion was expressed in 1952, the Herbert Committee has reported adversely on the extent to which the electricity supply industry leans on research efforts by outside organizations and its failure to devote sufficient resources to the planning of the future. The surveys of scientific and engineering man-power in Great Britain made for the Advisory Council on Scientific Policy by its Committee on Scientific Man-power have shown how poorly the research effort of the nationalized industries, in terms of man-power, apart from the Atomic Energy Authority, compares with that of industry in general; and in its last annual report the Advisory Council on Scientific Policy estimated expenditure on research and development in the United Kingdom by the public corporations at £6·9 million in a total of £477·8 million. The British Transport Commission in 1956 and in 1959 employed a smaller percentage of scientists and engineers in proportion to the total number of workers employed in the industry than in any other nationalized industry (0·25 in 1959 compared with 0·9 in the Airways Corporations and 0·8 in the National Coal Board).

These circumstances alone give special interest to the Select Committee's examination of the adequacy of the research organization and programme of

---

* Report from the Select Committee on Nationalized Industries, together with the Proceedings of the Committee, Minutes of Evidence and Appendices—British Railways. Pp. cvi+505. (London: H.M. Stationery Office, 1960.) 22s. 6d. net.

British Railways. The memorandum submitted to the Committee by the Commission emphasizes that the Commission regards its primary function as the provision of a transport service, and, as its suppliers undertake research and development, it has relied to a large extent on these suppliers for research, although it appreciates that in certain fields it must conduct its own research. As examples, the memorandum quotes problems concerning the interaction of vehicle and track, stresses in rails, corrosion, maintenance troubles, the interaction between equipment supplied by different manufacturers and field-trials on all types of transport. The total annual cost of identifiable research and development within the Commission is estimated at £2 million, of which some £700,000 is for research, 90 per cent being for the Railways, according to Sir Brian Robertson. Much of this, however, is for day-to-day advice and routine investigations. The research organization has been built up on lines recommended by a committee of scientists in November 1948. It provides for a technical committee and a research advisory council; a chief of research, assisted by a research co-ordination committee and with a small research department at headquarters; separate research departments for British Railways and Docks and Waterways, and for London Transport; and for electric traction research and operational research. The memorandum emphasizes the contact maintained with the Department of Scientific and Industrial Research and other Government departments, with the National Research Development Corporation, its membership of some thirty research associations and its contribution to the Office for Research and Experiments set up by the International Union of Railways to undertake co-operative research on common and technical problems and to pool the means of technical research.

In examination before the Committee, Sir Brian Robertson agreed that far too little was being spent on research, but he directed attention to adverse criticism which had been incurred when the Commission extended its facilities by building a small laboratory at Muswell Hill for servicing the Southern Region. Railway systems all over the world need laboratories and facilities for research, and it is obvious from Sir Brian's remarks that an increase in public understanding is essential if research activities are to be extended and strengthened. He referred particularly to the problems arising in the contact of rail and wheel as requiring fundamental research, but claimed that the Commission has itself stimulated some fundamental research by its suppliers. British Railways is at present engaged in fundamental measurements of currents generated at various parts of the electrification system, currents generated in cables alongside and mechanical measurements of the movements of vehicles in service on its new 25-kV. system. The new laboratory projected at Derby, where the expanded research department is to be located, would increase the annual expenditure on research by about £130,000 to £150,000; and the memorandum submitted to the Select Committee points out that the scientific background to the dynamic problems involved in the introduction of long welded rail is still very obscure and difficult, and, a long-term research project dealing with this is being assisted by one of the universities. There is also a special panel concerned with permanent-way problems which constitute the more important research projects.

Little emerged in the evidence before the Select Committee to indicate the magnitude of any deficiency in the research effort of British Railways; but although the Transport Commission admits that expenditure on research is too low and is building up its resources, every plea for increased expenditure on research comes under critical scrutiny both of the Government and of the Press, and, like most expenditure on research, is difficult to justify on purely economic grounds. The Select Committee accepted the contention that a comparison with sums spent by other industries is not valid because railways are not a production industry; it is a question rather of seeing what needs to be done and then doing it. Nor does the report offer any real criticism of the organization for research. The Research Advisory Council appears to be accepted, and the arrangements for co-ordination of research regarded as satisfactory.

It is possible that the relative expenditure on railway research in Britain is considerably less than in other countries, and the Select Committee seems satisfied that British Railways would benefit by increased expenditure on research, though it is difficult to assess how much more should be spent; the Transport Commission considers that the additional expenditure which will follow the completion of the new laboratories at Derby will bring research expenditure to the limit that its research staff can handle efficiently. Efficiency in research depends, in fact, on an adequate technical staff, and, if full value is to be obtained from increasing investment in research, it is essential that British Railways should attract larger numbers of technical staff of the highest quality. Sir Brian Robertson seems confident that the new laboratories will enable British Railways to obtain the kind of men needed, but probably the most disturbing feature of the Select Committee's whole report is the position it reveals of inadequate resources in respect of technical staff.

The memorandum on man-power, productivity and training submitted by the Transport Commission gives the number of technical staff at the end of February 1960 as about 7,700 out of a total staff of some 519,000 at the end of December 1959. Although rates of wastage have varied between 7 and 8 per cent per annum, it has been possible during the past four years to increase the number of technical staff by more than a third; but among engineering graduates, of whom only 512 were employed in 1959, the wastage may be as high as 15 per cent. A further memorandum on qualified engineers and scientists puts the total of such staff at 1,641 in 1959 compared with estimated requirements of 2,031, and difficulties are noted in recruiting qualified engineers and scientists for some departments. There are at present 52 student engineers in training in 'sandwich courses' throughout Britain, and 35 young students from the railways are attending courses in engineering at half a dozen technical colleges or colleges of technology.

These figures indicate that the total number of professionally qualified scientists and engineers employed by British Railways at the end of 1959 has returned to the 1956 level of 1,501 after falling to 1,354 earlier in 1959. Nevertheless, an increase of only 5·8 per cent has been achieved compared with the 30·9 per cent estimated in the Survey of Scientific and Engineering Man-power in 1956. Admittedly, the British Transport Commission cannot offer the attractions of an expanding industry, but the relative increase in technical staff as a whole compared with professionally qualified staff implies some progressive lowering of quality at a time then the rapid technical changes of modernization alone clearly require the reverse. This failure in recruitment may be due to some uncertainty as to the permanency of the positions which the Commission can offer, in spite of assurances given by the Commission itself; it can equally be due to the lower salaries offered in the middle range, as Mr. Albu emphasized in the House of Commons.

It is possible to make too much of the wastage of engineering graduates. This may not be a serious matter from the point of view of the nation generally. It is the practice for young engineers in the early days of their careers to change jobs frequently to gain wider experience; but for the railways this wastage does not appear to be balanced by new recruitment of experienced men, and it seems clear also that the Commission is doing less than many industrial firms to assist recruitment from universities and technical colleges by providing scholarships to such institutions. Even at the technician-level, the numbers being recruited or trained are small, and this source has not produced the number of professionally trained engineers expected.

There are some differences in the recruitment of different classes of engineers, and while the Transport Commission regards the position as reasonably satisfactory with civil and with electrical engineers, that with regard to signal engineers is very different, although there is not here the wastage experienced in other fields. Difficulties in recruitment have, in fact, been great enough to cause the Commission to rely to some extent on technicians from abroad, and the effects of this particular shortage have been very serious and have led to a slowing down of electrification schemes in general. The shortage of qualified signal engineers is admitted to be a principal factor governing the speed of modernization.

The Select Committee sums up the situation by emphasizing that although technical staff has increased rapidly in recent years, in the main it has been staff lacking in any formal qualification. Undue reliance on recruitment from craft apprentices in the workshops and the high level of wastage have been particular factors, and although the situation is serious enough to lead one to expect the Commission to keep a careful eye on the comparatively few first-class engineers it employs, this has not been done. The Select Committee is not satisfied that the Commission has treated this matter with the urgency it deserves, and expresses surprise that no central records are kept of its professionally qualified staff.

One serious consequence of this shortage of qualified technical staff has been in the field of design, where it has clearly affected the Commission's operations during the period of modernization. The costly failure in the design of vacuum brakes for mineral wagons was probably due to this, and while the Select Committee agrees with the Commission that the railways should not seek to recruit sufficient technical staff to make them wholly independent of the design and research of those privately owned firms which manufacture locomotives, rolling stock and signal equipment, expert staff is essential to the railways for specifying what is wanted and for choosing between conflicting designs. This is particularly important at a time of major technical change, and while it seems to the Select Committee that the Commission chose the right priorities in its plans for modernization, it failed to recruit the technical staff which it recognizes as necessary for their execution.

There are other shortcomings of management to which the Select Committee directs attention, some of which are also of scientific interest. This question of scientific and technical staff, however, is probably the decisive factor, and it is essential that no political or financial controversy should be allowed to push it again into the background. The Select Committee has rendered very great service in this report by bringing this issue to the forefront; and although the progress of plans for modernization may help to remove some of the misconceptions which have hindered the recruitment of qualified young men into what is thought by some to be a declining industry, there is no doubt that scientists and technologists in general could do something to combat ill-informed or prejudiced criticism—particularly of the type which has made the Commission so diffident about increasing its expenditure on research. As the Select Committee points out in its general conclusions, the scientific and technical advances which have made Britain famous in other fields have not in recent years borne full fruit in the railways; for on the evidence received, a large-scale British railway system could undoubtedly be profitable. The number of improvements in hand, and the number of points at which further improvements can be made, support this; but this is not solely a matter of efficient management and of adequate scientific and technical resources—in staff as well as in equipment and finance. It is at least in part a matter of the climate of opinion; and in creating and maintaining the climate of opinion which will support the necessary deployment of resources, scientists and technologists have an indispensable part to play.

RUSSIAN GEOLOGY IN TRANSLATION

The Geology of the U.S.S.R.

A Short Outline. By D. V. Nalivkin. Translated from the Russian by S. I. Tomkeieff. Translation Editor: J. E. Richey. (International Series of Monographs on Earth Sciences, Vol. 8.) Pp. xii+170+1 map. (London and New York: Pergamon Press, 1960.) 100*s*.

IN recent years new geological maps of the Soviet Union have been published on the scales 1 : 5,000,000 (9 sheets: 1955), 1 : 2,500,000 (19 sheets: 1956), 1 : 7,500,000 (2 sheets: 1958), and 1 : 10,000,000 (1 sheet: 1960). For the first of these the Russian authorities have provided a legend in English. All are magnificent examples of geological cartography, with first-class colouring. The Russian edition of Academician Nalivkin's *Brief Sketch of the Geology of the U.S.S.R.* appeared in 1957, as a paper-back of some 50,000 words written in explanation of the 1 : 5,000,000 sheets. In 1959, an excellent German translation by Dr. E. Schroeder became available (*Fortschritte der sowjetischen Geologie*, Heft 2: Akademie Verlag, Berlin), but unfortunately this was accompanied only by mediocre maps, in black-and-white. The English translation by Prof. S. I. Tomkeieff is issued together with the two 1 : 7,500,000 sheets, specially colour-printed in Moscow for this edition, with place-names in Roman type. It is the first English text on the geology of Russia to be published in book form since the days of Murchison.

The work is, of course, no more than the title implies—a short outline. For each of ten structural divisions of the Soviet Union information is given on topography, stratigraphy, tectonics, magmatism and economic geology, and the range of the book is thus so vast that the coverage is necessarily thin, seldom with more than a few words on any one geological feature. But the observations often suffice to whet the interest, encouraging the specialist reader to search elsewhere for details. The translation is literal, and for the most part it is lucidly written, the few obscurities being due to misplaced punctuation and inadequate proof-reading. As an appendix, a new "Table of Geological Formations in the U.S.S.R." has been added. A special interest resides in the very fine map produced for the British publisher by the U.S.S.R. Ministry of Geology, in an edition of 5,000 copies. The price of the equivalent Cyrillic map (15,000 copies) was, however, only 10½ roubles, and it is unfortunate that the British publication (text with map) should cost five times the Russian original and three times the East German translation.

The publishers state that "this very important volume is the first of its kind to be written in any language". Nevertheless there are other important texts on Russian geology, recently produced overseas and little known to British readers. Among these is a short account (30,000 words) of the *Tectonics of the U.S.S.R.* by the late Academician N. S. Shatsky and Dr. A. A. Bogdanov, initially published in Russian in 1957 as an explanation of a 1 : 5,000,000 tectonic map (9 sheets: 1956). Recently this has been translated into German (*Fortschr. der sowj. Geol.*, Heft 1: 1958), French (Translation No. 1594, Service d'Information Géologique: 1958), and English (*International Geology Review*, No. 1: American Geological Institute, 1959). It provides a particularly readable description of the structural framework of the Soviet Union, drawn on broad lines, and is complementary to Nalivkin's summary.

For detailed information reference can now be made to an extensive Russian work (650,000 words) entitled *The Geological Structure of the U.S.S.R.*, written by more than 150 authors under the direction of Academician A. P. Markovsky and published (1959) in three large volumes. From this text it is possible for the first time to obtain a balanced account of the rock formations of any geological age in any region of the U.S.S.R. The first volume deals with geomorphology and stratigraphy, the second with magmatism and volcanicity, and the third with regional and continental tectonics; and an accompanying portfolio contains 1 : 7,500,000 geological and 1 : 15,000,000 geomorphological maps. The immense task of preparing a Western translation of this highly important monograph has been shouldered by M. Pietresson de Saint Aubin and M. J. Roger of the Centre National de la Recherche Scientifique in Paris, who have already published eight out of a total of 20 fascicules in French, at an average cost of no more than five to six francs per fascicule. This well-produced French work seems likely to remain the most comprehensive Western authority for a good many years.

None of the publications in Russian on the regional geology of the U.S.S.R. meets the present need for a simple, well-illustrated text-book suitable for use, in translation, by Western university students. A noteworthy *Short Course on the Geology of the U.S.S.R.* by Prof. E. Shlygin (Gosgeoltekhizdat, Moscow: 270 pp., 1960) has just appeared, to form a basis for teaching in Russian universities; but this useful catalogue of facts is too unleavened for digestion by British undergraduates. Other Russian texts are similar in character, instructive, but scarcely inspiring. Considering the outstanding advances made by Soviet geologists and the immense range of geological phenomena demonstrable on Russian soil it is surprising that educational books on regional geology are all somewhat turgid and dull.

C. F. DAVIDSON

THE CLOUD OF UNKNOWING

The Gods of Prehistoric Man

By Prof. Johannes Maringer. Translated from the German by Mary Ilford. (The Weidenfeld and Nicolson History of Religion.) Pp. xviii+219+63 photographs. (London: Weidenfeld and Nicolson, 1960.) 42*s*. net.

THIS volume is an English translation of Prof. Maringer's *Vorgeschichtliche Religion*, published in 1956. In accordance with Continental practice, the term 'prehistoric' is used in the absolute sense of world-wide pre-literacy, and thus excludes much of what is still prehistory in English parlance, even if it falls after 2000 B.C. The rendering of the original German text is on the whole adequate, though the translator is clearly unfamiliar with archæological terminology.

Prof. Maringer's avowed purpose is "to define the religious forms of the individual prehistoric periods, to trace the various processes of development, and to arrive at a picture of prehistoric religious manifestations as a whole". This is an exacting task, even for those who regard it as an attainable objective; and there are many prehistorians who will not. But even if one puts this philosophical objection to one side, it must be admitted that the author's treatment of his subject is very uneven in quality. He is clearly most at home with the hunting-magic and the fertility symbols of the Upper Palæolithic era, of which he gives a lucid and succinct account; but by contrast his treatment of later periods is superficial, and in places positively archaic. The whole problem of the symbolic iconography of the passage-graves of Atlantic Europe is scarcely discussed at all; and it is not encouraging to be told that Stonehenge consists of three stone circles, and is orientated to the sunrise at the mid-winter solstice.

The principal defect in this book, and indeed of the attitude to prehistory which it represents, is a failure to admit and to understand the inescapable limitations of archæological evidence. We can re-create the past meaningfully, from its surviving material remains, only to the extent that the physical results of human behaviour can be translated back into the states of mind of which they are the expression. In matters of pre-literate technology and economics, this process of translation is relatively easy and reliable. In the field of social and political institutions it becomes increasingly difficult; and for religion it is virtually impossible. Religion, in the last analysis, belongs to the world of ideas and emotions, and finds its physical expression only in ritual. But, in the absence of the written or verbal explanations available to the historian and the ethnographer, ritual cannot reliably be translated back into terms of belief, simply because there is no one-to-one correspondence between concept and action.

This difficulty is tacitly, though never consciously, recognized by the author in his frequent citations of modern ethnographic parallels for the phenomena of prehistory. But analogies of this kind serve only to enlarge the field of conjecture. They cannot be used to explain the rituals of prehistory, unless it is assumed that human behaviour has survived unchanged, as a kind of museum specimen, from the prehistoric past into the present. If there is one thing that archæology can demonstrate, it is the total falsity of this assumption.

AGRICULTURAL AVIATION

Report of the First International Agricultural Aviation Conference

September 15–18, 1959, Cranfield, England. Pp. 429. (The Hague: International Agricultural Aviation Centre, 1960.) 50*s*.; 7 dollars; 29 D.M.

Agricultural aviation is not yet so widely accepted in Europe as it is in the U.S.A., for example, mainly because in Europe the need is smaller and some of the difficulties are greater. Many contributors to this report come from Europe and are accordingly considering the value of work done from the air in high-farming areas.

N. D. Norman in a paper reviewing the economics of aerial contract work on farms, shows that costs are high and that earning power is limited by a short working season, by limited periods of flying weather and by the working-rate of the aeroplane on its main tasks of applying chemicals to crops. He shows how it is difficult to operate such a contract service profitably in England.

More information is required about each of several potential ways of raising income above expenditure before they can be offered to the industry. It is difficult, in this sphere, to predict that a change will cause an improvement, especially in countries of relatively small fields, dense populations and many hazards both to flying and of applying chemicals, some of which may not contaminate down-wind crops.

These and other matters of safety, legislation, operating techniques, equipment and aircraft, in fact almost the whole art of agricultural aviation, are touched on in the report, and the treatments are necessarily brief and qualitative. However, such subjects which form the basis of the industry might have been presented with more quantitative information than, with exceptions, the papers contain.

Thus, although the agronomic basis of aerial agriculture is surveyed by R. C. Amsden, the individual papers to support him provide only a little evidence to show how and where an aeroplane is either as effective as, or more profitable than, a ground sprayer. R. A. Powell shows that fertilizer distribution from an aeroplane can be as regular as that from most distributors on the ground. No other paper provides critical evidence to demonstrate what advantages an aeroplane has over a ground machine. Wheel damage, onset of disease in the wheel tracks, the value of timely application of pesticides and of fertilizers are mentioned, but without such data as would convince a farmer.

The dangers of low-level flying and of applying poisonous chemicals are considerable. D. Yeo reviews the dynamics of small particles in the air-flow near an aeroplane close to the crop and shows that although contamination of down-wind crops can be serious, precautions to prevent it can be successful. E. F. Edson and others show that no harm from toxic chemicals has been detected, except when accidents have occurred, but point out that the pilot has to take great care in order to prevent pollution completely.

In a countryside full of obstacles a pilot has to take great care of himself also. It is therefore questionable whether F. E. Weick's paper is as relevant for France as it may be for Florida. He quotes, without supporting evidence, 60–100 m.p.h. as a suitable flying speed. But Latimer–Needham's graphs in the economics section show that, at this speed, 90 per cent of flying time is consumed in half-mile long turns at the end of the field. Possibly, therefore, a lower flying speed is desirable in order to work more quickly, to be safe and also in order to fly close to the ground to avoid pesticide pollution. It is possible also that a monoplane has to give way to a rotary-wing aircraft as suggested in de Ree's paper.

The aircraft used at present are light monoplanes and war-surplus biplanes. Sir Miles Thomas points out how much better the helicopter is for the work. However, the helicopters used so far have been expensive and less reliable than fixed wing aeroplanes. The Kolibrie helicopter, as described by de Ree, seems an improvement in both respects despite its high fuel consumption. Surprisingly, the autogyro, which appears to have the merit of a helicopter for this work at the price of a light plane, receives no more than a mention along with ducted fans and other unconventional, vertical take-off aircraft.

European conditions may be sufficiently different from those in the United States and Australia for changes in aircraft, application techniques and organization of the work to be necessary, just as fertilizer and plant protection programmes differ. This report mainly poses the questions to which answers are needed to help the industry to prosper, and it is valuable for this alone. It is well produced, but an index would be helpful.

R. J. Courshee

THEORY OF BANACH ALGEBRAS

General Theory of Banach Algebras

By Prof. Charles E. Rickart. (The University Series in Higher Mathematics.) Pp. xi+394. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1960.) 79*s*.

THIS book gives a comprehensive and detailed account of the theory of Banach algebras, and should be of great value to research workers in this field. The subject is a very modern one, the foundations for a general theory being laid by Gelfand in a paper published in 1941, but announced in 1939 (Normierte Ringe, *Recueil Math.* (*Mat. Sbornik*), N.S., 9, 3; 1941).

The contents of the book are as follows. Chapter 1, "Fundamentals"; this includes definitions, the regular representations, complexification of a real normed algebra, the groups of regular and quasi-regular elements, topological divisors of zero, the spectrum, and normed division algebras. Chapter 2, "The Radical, Semi-simplicity and the Structure Spaces"; this includes ideals and difference algebras, representations, the radical, primitive Banach algebras, uniqueness of the norm topology and the fundamental isomorphism theorem, structure of semi-simple Banach algebras, the structure spaces, completely regular algebras and annihilator algebras. Chapter 3, "Commutative Banach Algebras"; this includes the carrier space and the Gelfand representation theorem, algebras of functions, the Šilov boundary, representations of the carrier space, homomorphisms of certain function algebras into a Banach algebra, direct-sum decompositions and related results and completely regular commutative Banach algebras. Chapter 4, "Algebras with an Involution"; this includes miscellaneous properties of *-algebras, commutative *-algebras, self-dual vector spaces and *-representations, representations on Hilbert space, positive functionals and irreducible *-representations, symmetric *-algebras, general properties of B*-algebras, structure of ideals and representations of B*-algebras, and Banach*-algebras with minimal ideals.

There is, finally, a lengthy appendix on examples and applications, under three headings: (*a*) "Algebras of Operators"; (*b*) "Algebras of Functions"; (*c*) "Group Algebras". Included in (*a*) are the algebras $\mathfrak{B}(\mathfrak{X})$ and $\mathfrak{B}(\mathfrak{H})$, the algebra $\mathfrak{I}\mathfrak{C}$ of compact operators, the Schmidt-class $\mathfrak{I}\mathfrak{S}$, the trace-class $\mathfrak{I}\mathfrak{T}$, W^* and AW^* algebras, and spectral operators; under (*b*) are included the algebra $C(\Omega)$ for certain special Ω, the l^p-algebras, functions with absolutely convergent Fourier series, functions of class $C^{(n)}$, continuous functions of bounded variation, holomorphic functions of one variable, holomorphic functions of several variables, a non-self-adjoint algebra with Šilov boundary equal to the carrier space, non-existence of the Šilov boundary, algebras of set functions on the line, some radical algebras, and algebras of power series; while (*c*) includes the algebra $L^1(\mathfrak{G})$, locally compact abelian groups, group algebras of a compact group, almost periodic functions on groups, and group algebras of operators.

The book is evidently written for mature mathematicians who already have at least a slight acquaintance with the subject. Those not so equipped would, apart from the difficulty of the text, find the lack of simple illustrative examples in the four chapters a serious stumbling-block. The appendix would not supply this need, as the applications are given in a very condensed manner, requiring a high degree of maturity from anyone hoping to profit from it. However, for professional mathematicians having already some knowledge of the subject, the book will undoubtedly be of great value.

R. G. Cooke

DR. ERIC C. S. MEGAW

A Backroom Boy

By Arthur Stanley. Pp. vi+106. (Belfast: W. Erskine Mayne, Ltd., 1960.) 10*s*. 6*d*. net.

THIS little book, written by a father as a memorial to his brilliant son, describes the life of Dr. Eric C. S. Megaw, who was director of physical research at the Admiralty when he died at the early age of forty-eight years.

As a schoolboy Megaw acquired a sound knowledge of the French language, including facility in speaking it. Also, an interest in mechanical things led him at the age of fourteen to a keen interest in amateur radio experiments. This was encouraged by a short period in the Signals Section of the Officers' Training Corps, and in 1924 he was reputed to be the first amateur to send radio signals from Ireland. In the following year he established the first radio contact between Ireland and Australia.

The book outlines in the author's 'domestic' style Megaw's scientific career which was described in the obituary notices published in *Nature* (177, 409; 1956). The factual account is supplemented by extracts from his personal letters, which illustrate his acute power of observation and close attention to the work in hand. The final chapters of the book comprise extracts from letters received by Mrs. Megaw from officials and colleagues who were closely associated with, and very appreciative of, the scientific work of her late husband.

This volume is prefaced by a letter from Sir Eric Ashby, formerly vice-chancellor of the Queen's University of Belfast, where Megaw obtained both his bachelor's and doctoral degree in science. Sir Eric welcomes this memorial as a reassurance to both teachers and students, in describing "how the most satisfying career can be built on quiet, steady work, without publicity, without ostentation, and without neglecting family life, or music, or literature".

A brief appendix lists Megaw's published papers, including that with two of his colleagues, which was published posthumously and was awarded the highest premium of the Institution of Electrical Engineers.

R. L. Smith-Rose

Structure and Properties of Thin Films

Proceedings of an International Conference held at Bolton Landing, New York, September 9-11, 1959. Edited by A. Neugebauer, J. B. Newkirk and D. A. Vermilyea. (Sponsored by Air Force Office of Scientific Research, Air Research and Development Command, and the General Electric Research Laboratory.) Pp. xiv+561. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 120*s*. net.

THERE are so many scientific conferences organized nowadays that one wonders how anyone has time to carry out the research which is discussed at such meetings. It is inevitable that many scientists who would like to participate in a particular conference are prevented from doing so; for these people a well-produced book of Proceedings can be invaluable. Even the participants can profit from a more leisurely perusal of the flood of new ideas. The present report is an excellent example of its kind. It was published within a few months of the conference and is extremely well produced, both typographically and editorially.

The papers are divided into six sections dealing with the formation of thin films, with their mechanical, electrical and magnetic properties, with chemical interactions at the surface and the general theory of surfaces. A regrettable omission is a section on the optical properties of thin films, although optical techniques figure occasionally in the individual papers. It would be invidious to select any particular report from so wide a field; many of the papers have a distinct technological bias and the research described is aimed chiefly at a particular application, for example, computer devices. It would have been better if the title had been restricted to thin metal films—the papers deal almost exclusively with the properties of such interesting substances as aluminium, copper, gold, iron, nickel, silver, etc.

The editors are to be congratulated on the high standard of the illustrations and on the provision of both an author and a subject index. The discussions of the papers are fully reported and in many cases are quite as stimulating as the original report.

J. RING

An Introduction to Differential Geometry

By T. J. Willmore. Pp. x+317. (Oxford: Clarendon Press; London: Oxford University Press, 1959.) 35*s*. net.

THE elegant domain of classical differential geometry in three dimensions is now somewhat out-moded. But it retains a practical value, for example, in design problems, and forms a good, perhaps essential, prelude to work in n dimensions. Dr. Willmore's book deals with both aspects. In the first part, it gives the main results about curvature and torsion of curves and curvature of surfaces, using vector notation; this is very clear, though some use of kinematical concepts might have rendered it more vivid. There is also an excellent introduction to differential geometry in the large, a topic of increasing importance not generously treated in English texts. In the second section, the space is n-space, and tensor algebra and tensor calculus are developed *ab initio* to cope with Riemannian geometry and with the generalizations of the results in Part I. There is a good supply of exercises, mainly from University of Liverpool examinations, and plenty of bibliographical references for further reading. The first part of the book must be counted as essential to any honours mathematics student, while the second part forms a valuable first text for those who intend to begin research in global theory and differentiable varieties.

General Degree Applied Mathematics

By S. L. Green and J. E. C. Gliddon. Pp. iv+346. (London: University Tutorial Press, Ltd., 1959.) 18*s*.

THIS text, with Mr. Green's *Dynamics*, covers the applied mathematics (excluding statistics) required by the London B.Sc. (General), revised regulations. The authors have produced just the book for the average undergraduate, who will not complain, may even rejoice, at the limitation in outlook values imposed by a careful observance of the syllabus. The book deals with virtual work, statics of beams and strings, normal modes, vibrations of strings, hydrodynamics, gravitation and electrostatics. Vectors are used freely but sensibly, though it is sad to see that they cannot yet be taken for granted at this level, and require sixty pages of treatment. The bookwork is presented in clear and easy style; in some places, as, for example, in the vector integral theorems, geometrical intuition is used freely to supplement or avoid analytical rigour. Every point is driven home by worked examples, carefully selected from recent examination papers, while the British tradition of plenty of exercises for the reader is fully respected. It is hard to think of a better book for the particular purpose; and if the purpose seems not always sufficiently up to date, that is no fault of the authors The revised syllabus itself may soon demand revision.

Nutrition and Physical Fitness

By Dr. L. Jean Bogert. Seventh edition. Pp. xi+613. (Philadelphia and London: W. B. Saunders Company, 1960.) 6 dollars; 42*s*.

THE earlier editions of Dr. Bogert's book had the laudable aim of presenting a comprehensive view of the whole subject of nutrition in fairly simple language suitable for students who had no previous knowledge of chemistry. As it is more or less impossible to discuss many facets of nutritional science without some reference to their chemical connexions, the present edition has been improved by inclusion of some simplified material on the chemical constitution of carbohydrates, fats and proteins. Some graphically illustrated ideas on the digestion and absorption of nutrients and on the functions of vitamins and enzymes are included. The first two parts of the book on body-needs and body-functions have been considerably rewritten, and many illustrations and diagrams have been added. Lists of references for supplementary reading have been extended, which increases the usefulness of the text. Within the limitations necessarily imposed by the need to simplify statements and to be dogmatic on points which might otherwise be obscure for the students for whom the book is intended, *Nutrition and Physical Fitness* is a good teaching text-book for introductory courses in nutrition. Its ideas on meal planning are designed for the American way of life, but they can be adapted for other countries. Some notes on food fallacies and their refutation might well be studied by all who have concern with knowledge of foods and nutrition.

RELATIVE EFFICIENCIES OF INDIAN LANGUAGES

By Dr. B. S. RAMAKRISHNA, K. K. NAIR, V. N. CHIPLUNKAR, B. S. ATAL,
V. RAMACHANDRAN and R. SUBRAMANIAN

Department of Electrical Communication Engineering,
Indian Institute of Science, Bangalore, India

THE concept of information and its measure developed in telecommunication engineering during the past decade or so have made it possible to investigate certain questions in linguistics in a quantitative manner. We describe here briefly a method of comparing the relative efficiencies of different languages and their scripts as means of communication. The efficiencies of some of the modern Indian languages, namely, Hindi, Marathi, Tamil, Malayalam, Telugu and Kannada, have been evaluated with respect to English, which was chosen as a common reference. The concepts on which the comparisons depend, however, are of general applicability and are by no means restricted to Indian languages alone. We shall, indeed, introduce these notions here by referring to a similar comparison between English and German which we made prior to the study of the Indian languages.

The key-note of this investigation is that where different languages can be employed to serve the same end-purpose, we can compare their relative performances as alternative means of communication using the tools of information theory. This work is based on two notions: the first of these is that, if we accept that language is a code for the purpose of communication, linguistic statements which convey the same meaning in different languages can be considered as alternative forms of encoding the same semantic content into linguistic symbols. The semantic equivalence of messages in different languages, however, does not imply that their informational entropies are also equal. (The informational entropy associated with a symbol such as a letter, phoneme, etc., of a message is defined in communication theory, in a manner analogous to the thermodynamical entropy, as $-\Sigma_i p_i \log p_i$, where the p_i's represent the probabilities of occurrence of the symbols obtained on a statistical basis from sufficiently long messages. The total entropy of a message containing N symbols is therefore $-N\,\Sigma_i\, p_i \log p_i$. When the logarithms are taken to the base 2, the unit of informational entropy is called a bit or, sometimes, a selective bit, to emphasize the selective role of information. The definition of entropy can be extended to include the statistical constraints between symbols, but we shall use here only the entropy based on letter probabilities, as all our comparisons are based on letter frequencies only. For a more detailed discussion of the concept of entropy see, for example, ref. 1.) It is well known that the entropy of a message is the proper measure of the cost of its transmission, storage, etc. It follows, therefore, that the entropies of semantically equivalent statements in different languages constitute inverse measures of the relative efficiencies with which the languages encode semantic content into linguistic symbols.

To obtain semantically equivalent statements in two languages one must take suitable samples of texts in one of the two languages and their translations in the other. Thus in a comparison of English and German[2] (two closely related languages) it was found that when the original text was in English and the translation in German, 171,017 bits of information in English are equivalent to 207,590 bits in German, which seems to imply that one bit in English has about the same semantic value as 1·21 bits in German. On the other hand, with the original in German and the translation in English, 163,984 bits in English prove to be semantically equivalent to 175,491 bits in German, leading now to an exchange ratio of 1·07 bits of German for one bit of English. From similar comparisons of English and different Indian languages, it appears that the exchange ratio is always relatively more favourable to a language when the original is taken in that language.

This situation can be explained on the following information theoretical model of translation, namely, that translation is a process of the transformation of the code in which we aim at leaving the semantic content invariant despite a certain inherent tendency for equivocation or semantic ambiguity arising in the translated text, which, in the terminology of the communication theory, may be called semantic noise. To preserve the semantic content, therefore, the translator must overcome the noise by using additional bits of information. Thus each bit has to be paid for—not only its proper equivalent in the language of translation but also the additional bits required to overcome the noise. If we assume that x bits in German are the proper semantic equivalent of one bit in English and that y additional bits are needed to overcome the noise associated with the translation of each bit in both directions, we obtain the pair of simultaneous equations:

$$171{,}017\ (x + y) = 207{,}590$$
$$175{,}491\ (x^{-1} + y) = 163{,}984$$

for the English to German and German to English translations respectively, which yield $x = 1{\cdot}15$ and $y = 0{\cdot}065$. This makes English relatively more efficient in that it requires about 15 per cent fewer bits for transmitting the same semantic content than does German. Similar comparisons established the relations between English and the different Indian languages as shown in Table 1.

Table 1. SEMANTIC EFFICIENCIES OF INDIAN LANGUAGES RELATIVE TO ENGLISH

Indian language	Number of bits semantically equivalent to one bit in English x	Additional bits required for each bit translated y
Hindi	1·34	0·22
Tamil	1·09	0·17
Malayalam	1·24	0·08
Telugu	1·14	0·04
Kannada	1·14	0·07

Now what makes a language more or less efficient than another for communicating semantic content ? Evidently a language becomes less efficient either if ideas are expressed in the language in a redundant form or if it uses relatively longer words to express the same notions. It is possible that the relatively high semantic efficiency we have noted above for English could be due to the large number of short words in that language. (It may be noted that the average length of a word in English is about 4·5 letters, whereas it is about 6 letters in German.) Further analysis is needed before we can partition the inefficiency of a language into components attributable to these two causes.

The other notion introduced here relates to the comparison of the verbal-to-orthographic transcription schemes of different languages. Just as speech is a code for expressing our thoughts, so do the different alphabetic and syllabic forms of writing constitute codes for transcribing the sounds of speech into written symbols. Whenever, therefore, it is possible to transcribe a given phonetic pattern by two or more scripts, we may regard the corresponding written symbols as alternative codes the phonetic content of which remains the same. We have thus a basis for comparing different scripts, once we have chosen a criterion of merit.

One of the chief merits of a script is the speed with which it can be written. If we digress for a short while to examine the history of writing, we see how the evolution of different scripts was greatly influenced by the speed with which their characters could be 'written' on the materials available during different periods. The transition from pictographic writing to the use of word-signs, then the syllabary, and finally the alphabet in Mesopotamia, and likewise from the hieroglyphic writing to the hieratic and demotic scripts in Egypt, have all been steps towards achieving faster speed. Speed, however, has never been the sole determinant. It would be more appropriate to say that the evolution of writing follows a compromise between the opposing needs of speed on one hand and legibility on the other. Indeed, the progress of writing seems to be governed by principles similar to those existing in human speech. For example, it will be recalled that some years ago Zipf[3] had observed that if the words in a language are ranked in the order of their frequency of occurrence then the product of the rank and the frequency of each word is nearly a constant. Information theorists[4] have tried to explain this relationship on the basis that it costs a certain effort to speak each word, and that this cost may be taken proportional to the length of the word. It is then shown that Zipf's relation between the rank and frequency is precisely the one which makes the average cost per word a minimum in accordance with Zipf's Principle of Least Effort. A parallel case is to be found in the syllabic scheme of writing used in the Indian languages : the vowel sounds which are more frequent than the consonantal sounds are not written separately when they follow a consonant, but merely modify the consonantal symbols with which they are associated, thus minimizing the effort needed in writing.

Zipf has also directed attention to how certain words acquire multiple meanings in a language as a result of two opposing forces, namely, the economy of the speaker, who favours the fewest possible number of words to refer to whatever he means (just one, if feasible, according to Zipf) and the needs of the listener, who favours a separate word for each 'referent' which the speaker intended to refer. In each language a balance suited to the needs of its community is achieved between these opposing requirements by certain words acquiring multiple meanings, thus limiting the size of its vocabulary. An analogous principle also seems to underlie the evolution of writing at various stages of its development. When picture writing was found to be inadequate as a means of unambiguous communication to the growing needs of settled communities, the early scribes had to increase the detail in the picture as well as their number. The device of using the same picture sign to represent homonyms (that is, words having the same sound value but different meanings) which was then developed helped the scribe to achieve some economy in writing. A further step in this direction was the juxtaposition of the symbols corresponding to the different syllables in a word whenever this was possible. This process reduced even further the number of different signs required for communication because the total number of different syllables required is generally less than the number of words. Thus, we are told (see, for example, the article on "Recording and Writing", by S. H. Hooke, in *A History of Technology*, 1, Oxford Univ. Press, 1954), that while there were about 2,000 word signs in use in Mesopotamia about 3600 B.C., by the end of the fourth millennium the syllabary consisted of only about 600 signs. The principle of alphabetic writing in which the symbols came to represent the individual speech sounds was the last step which further reduced the number of different symbols needed for writing. On the other hand, in the development of the miniscule or the lower-case letters from the majescule or upper-case letters, we have an instance in which legibility rather than the desire for speed played the main part. As the capital letters were written in haste, the characters suffered in legibility, and to preserve the distinction among the letters some of them were given ascending strokes as in *k* and *h* and others descending strokes as in *p*, *q*, etc.

Whatever may be the factors influencing the evolution of writing, we shall accept here the Roman and Indian scripts in the form in which they are handed down to us and confine ourselves to the question whether the alphabetic form of writing of the Roman script has any advantage over the syllabic form of writing of the Indian languages in the matter of speed. To answer this question, writing was treated as an acquired skill, and a subjective test minimizing the effect of personal factors was designed as follows : from the phonemes common to English and the Indian languages (which account for more than 80 per cent of their occurrences in any of these languages) a set of 100 nonsense syllables were composed and were then transcribed by the Roman script and the several Indian scripts on separate test sheets. A number of subjects (about 60) who had had sufficient (but not necessarily equal) practice in writing the Roman script and one of the Indian scripts were asked to copy these syllables on the same sheets and in the same scripts. Thus a subject who could write Roman script and Hindi script (Devanagari) wrote the same 100 sounds in Roman and Devanagari scripts when he completed the test sheets. The times taken by the different individuals in the two scripts were noted. This procedure was followed with different types of syllables such as *CV* (consonant vowel), *VC*, *CVC*, *CCV*, etc., and the several Indian languages, using each time Roman script as a common reference. For each type of syllable, the subjects furnish a bivariate sample of data; namely, the times required for transcribing the same phonetic content by the Roman script and one of the Indian scripts.

Since the observed times are likely to be influenced by the extent of practice of the individuals in the two scripts, the subjects were classified on the basis of their practice in writing the two scripts into three categories, namely, those that have relatively more practice in writing the Roman script, those that have relatively more practice in writing the Indian script, and those that have about equal practice in both scripts. The observed writing times will not only be influenced by the scripts themselves but also by the writing speed and practice of the individuals in them, as well as random errors. Considerable attention was therefore given to investigating the significance of the effect of practice on the observed writing times. Study of the cross-correlation between the writing times of the individuals in the two scripts showed that, in general, a person who is a fast (or slow) writer in one script also tends to be a fast (or slow) writer in the other script, irrespective of the extent of his practice in the two scripts (provided he has had practice beyond a certain minimum).

Following now our assertion that the different scripts are but different modes of transcription, we can now classify the mean writing times of the different categories with the script and the practice as the two variables of classification[5]. Table 2 shows a typical partition of the mean writing times ξ_{ij} of the different categories in the Roman and an Indian script (Telegu) into components which are attributable to the effects of (1) script, (2) practice and (3) random errors measured from the grand mean $\mu = \Sigma_{ij}\,\xi_{ij}/6$. The cell means ξ_{ij} $(i = 1, 2, 3;\ j = 1, 2)$ differ from each other not only because of population variance and random errors, but also because of intrinsic differences in the scripts and differences in the practice of the different categories.

We assume that any cell mean ξ_{ij} can be written as:

$$\xi_{ij} = \mu + \alpha_i + \beta_j + \varepsilon_{ij}$$

where μ is the same for all the cells, α_i $(i = 1, 2, 3)$ is a constant for all cells in the i-th row, β_j $(j = 1, 2)$ is the same for all the cells in the j-th column and ε_{ij} a random variable which varies from cell to cell and has a sampling distribution with mean zero. (This assumption implies that there is no interaction between the row effects and column effects.) The quantities α, β and ε are determined so that

$$\sum_{i=1}^{3}\alpha_i = 0,\quad \sum_{j=1}^{2}\beta_i = 0,\quad \sum_{i=1}^{3}\varepsilon_{ij} = \sum_{j=1}^{2}\varepsilon_{ij} = 0 \qquad (i = 1, 2, 3;\ j = 1, 2)$$

Table 2. CLASSIFICATION OF THE MEAN TRANSCRIPTION TIMES FOR THE *CV* TYPE OF SYLLABLES WITH SCRIPT AND PRACTICE AS THE TWO VARIABLES AND THE PARTITION OF THESE MEANS INTO COMPONENTS DUE TO THE EFFECTS OF SCRIPT, PRACTICE AND RANDOM ERRORS

Category of practice	Mean transcription (on writing) times of *CV* type syllables	
	In Roman script (sec.)	In Telugu script (sec.)
English practised category	$\xi_{11} = \mu + \alpha_1 + \beta_1 + \varepsilon_{11}$ $176 = 164 + 7 + 13 - 8$	$\xi_{12} = \mu + \alpha_1 + \beta_2 + \varepsilon_{12}$ $166 = 164 + 7 - 13 + 8$
Telugu practised category	$\xi_{21} = \mu + \alpha_2 + \beta_1 + \varepsilon_{21}$ $192 = 164 + 7{\cdot}5 + 13 + 7{\cdot}5$	$\xi_{22} = \mu + \alpha_2 + \beta_2 + \varepsilon_{22}$ $151 = 164 + 7{\cdot}5 - 13 - 7{\cdot}5$
Equal practice category	$\xi_{31} = \mu + \alpha_3 + \beta_1 + \varepsilon_{31}$ $163 = 164 - 14{\cdot}5 + 13 + 0{\cdot}5$	$\xi_{32} = \mu + \alpha_3 + \beta_2 + \varepsilon_{32}$ $136 = 164 - 14{\cdot}5 - 13 - 0{\cdot}5$

In our case, the quantity μ establishes a common reference of the mean writing time for the different scripts and the practice groups, and serves as the balance point about which the practice effects represented by the α's and the script effects represented by the β's produce deviations. The row-variables measure the effects of practice of the different categories from this common reference and are thus independent of the particular script. A positive value of α for a particular practice-category implies that its members are on the average slow writers, whatever the script. Similarly the column-variables β's measure the effects of the scripts independently of the practice of the different categories. A positive value of β for a script implies that it is a more time-consuming one than the other. If there were no differences in practice among the three categories, $\alpha_1 = \alpha_2 = \alpha_3 = 0$ and the mean writing times in the Roman and the Indian (Telugu) scripts would have been $\mu + \beta_1$ and $\mu + \beta_2$, apart from the effect of random variations represented by the quantities ε_{ij}, which we may expect to tend to zero as the sizes of the samples are increased. The quantities $\mu + \beta_1$ and $\mu + \beta_2$ are therefore the proper measures of the times required for transcribing the same phonetic content by the Roman and Telugu scripts, free from the differences in practice of the different categories The numerical values of the quantities ξ_{ij} and their components μ, α's, β's, etc., are given immediately below them in each cell for the *CV* type of syllables We can now arrive at an estimate of the relative time requirements of the two scripts by similarly analysing the data for the other types of syllables and taking the relative frequencies of the different types of syllables in the Indian languages into account.

The final results show that while in the case of *CV* and *CCV* type of syllables most of the scripts of the Indian languages studied here have a slight advantage (requiring about 10 per cent less time than the Roman script) this is not the case in respect of the *V*, *VC* and *CVC* type of syllables. This might have been anticipated, as the syllabary enables the entire *CV* or *CCV* type of syllable to be represented by a single character with relatively minor modifications. It is also evident that even in the cases where the Indian scripts save in time, this saving is partly or even completely off-set by the fact that a cursive hand is not possible with them to the same extent as with the Roman script. It appears that the adaptation of the Roman script to Indian languages results in a reduction of about 5 per cent in the writing time for Tamil, Kannada and Hindi, and an increase of about the same magnitude in the case of Telugu and Malayalam.

While the numerical results given here are subject to the limitations inherent in the statistical sampling that is necessary, we should like to focus attention on the possibility of investigating such questions in a quantitative manner. It is proposed to publish the details of these investigations in the form of a monograph.

BRITISH NORMAL THRESHOLD OF HEARING

By L. S. WHITTLE and D. W. ROBINSON

Applied Physics Division, National Physical Laboratory

IN 1954 a British Standard[1] on the normal threshold of hearing for pure tones by earphone listening was published. The values specified in the standard are based on two investigations[2,3] carried out in the United Kingdom in which tests were made on more than 1,200 ears of otologically normal subjects of ages 18–25 years.

A subsequent investigation by Knight and Coles[4] has added further weight to the reliability of the Standard, the values for 74 male subjects agreeing within 1·4 db. at frequencies from 250 to 4,000 c./s. inclusive. Further experimental confirmation has been given by Hinchcliffe[5].

In the British Standard the threshold is expressed in two ways: (*a*) As the minimum audible pressure measured at the entrance to the external auditory meatus, when the sound pressure is produced by an earphone applied to the ear. (*b*) In terms of the sound pressure set up in an artificial ear complying with B.S.2042 (ref. 6) by an earphone of a specific pattern when actuated by the voltage corresponding to the normal threshold referred to in (*a*).

We are here concerned only with the latter, termed the 'equivalent normal threshold sound pressure' (ENTSP).

The ENTSP is dependent on the pattern of earphone, and for the British Standard this is the type 4026*A* manufactured by Standard Telephones and Cables, Ltd., London. If the ENTSP for earphones of other types is required, this is obtainable by means of loudness-balancing against a standard earphone of the reference pattern, and for this purpose the British Standard[1] recommends the employment of at least twenty observers. While loudness balancing must remain, for the time being, the primary method of calibrating earphones for audiometric use when the type involved is other than the appropriate national reference pattern, the accumulation of test results now makes it possible to present, at least provisionally, some values of the ENTSP corresponding to the British Standard threshold of hearing for a few of the other earphone patterns in common use.

The results of such comparisons carried out over the past few years at the National Physical Laboratory are presented in Table 1. Meanwhile, an investigation has also been carried out to assess the reliability of these subjective transfers[7].

By measurements of the objective sensitivities of earphones of these types on the B.S. artificial ear and 9*A* coupler, respectively, we are able also to express the British Standard threshold of hearing in terms of sound pressure in the 9*A* coupler (columns headed '9*A*'). The information is then in a form in which direct comparison can be made with results on earphones and audiometers calibrated to other threshold standards, principally American (for example, those given in refs. 8 and 9), which are based on the 9*A* coupler.

It is well known that a considerable divergence exists between the current British and American

standards[1,8]. However, recent American work[10] has shown that when thresholds are measured under similar experimental conditions and when the same method of selection of subjects is used, the discrepancy between the threshold of hearing measured in the United States and in Britain to a large extent disappears. At the present time we are able to make the provisional estimate of the residual difference shown in Table 2, as a result of interlaboratory exchanges of the actual earphones employed, together with some indirect subjective transfers discussed below. This should not be regarded as final, however, as the resolution of this discrepancy is at present under consideration by Technical Committee 43 of the International Standards Organization.

To illustrate the comparison between the new American data[10] and the British, we have derived from American data six estimates of the British threshold referred to various earphones, and these are shown for comparison with the British data under the columns 'derived 9*A*' in Table 1. The values have been obtained as follows: To the equivalent threshold sound pressures for the various earphones (given in refs. 8, 9 and 11 in terms of the current American Standard) we have added a correction (Cook, R. K., private communication) to bring them into line with the new data of Albrite *et al.* In the case of the *TDH*39, values already expressed in terms of Albrite's threshold were available as a result of subjective comparisons between the *TDH*39, 4026*A* and 705*A* types carried out by A. Glorig (private communication). To the corrected values we have added a further adjustment for the estimated difference between the Walter Reed and British threshold determinations, shown in Table 2.

The resulting values are the 'derived 9*A*' ENTSP. The extent to which these depart from the values shown in the corresponding columns headed '9*A*' is a measure of the combined subjective errors involved in transfers between the reference earphones and those of the other types shown, objective errors (which are probably small), and the failure of the particular earphones used in the various comparisons to conform exactly to pattern (that is, the ratio of subjective sensitivities may not be precisely equal to the ratio of sensitivities on the artificial ears). The departures are in most cases quite small and non-systematic (mean 1·2 db., maximum 3·5 db.) over the range 250–6,000 c./s., which is regarded as satisfactory in view of the indirectness of some of the comparisons. For applications of Table 1, however, we would recommend the adoption of the values headed '9*A*', which were obtained by direct comparison of the response of earphones on a B.S. artificial ear and a 9*A* coupler, respectively.

The work described was carried out as part of the research programme of the National Physical Laboratory, Teddington, and this article is published by permission of the Director of the Laboratory.

THE RE-SURVEY OF TYPHOON EFFECTS ON JALUIT ATOLL IN THE MARSHALL ISLANDS

By DR. DAVID I. BLUMENSTOCK, DR. F. R. FOSBERG and CHARLES G. JOHNSON*

IN a previous issue of *Nature*[1], one of us (D. I. B.) reported briefly on the first findings of a field-party of seven scientists who visited Jaluit shortly after it was struck by Typhoon *Ophelia* on January 7–8, 1958. More recently, some detailed results of this initial survey have been given in an article by Dr. Edwin D. McKee[2] and in a series of papers by all seven participating scientists which is in the press[3].

Meanwhile, the present authors visited Jaluit Atoll during the period October 19–29, 1960, to observe in general what changes have occurred since the first survey, and especially to learn what effects have persisted most strongly and may long be expressed on the atoll. In this re-visit, sponsored by the Pacific Science Board of the National Academy of Sciences–National Research Council, the Office of Naval Research, and the Trust Territory of the Pacific Islands, we were greatly aided by Mr. Eric Knudsen, who is the resident agriculturist at Jaluit for the Trust Territory. It is the purpose of this article to report very briefly and in a preliminary sense on our findings during this re-survey.

General findings. The initial survey revealed that the typhoon had created rubble bars on the reef-flat on the ocean side of the eastern islets and had created other bars or extended existing bars on the lagoon reef-flats of some of these same islets. The typhoon had also laid down thick sheets of coral gravel across large sections of the eastern islets, had scoured out channel-ways, and had destroyed or felled 70–90 per cent of the trees throughout the eastern islets and 20–50 per cent throughout the western ones. Economically, the damage was so severe that the Trust Territory Government had to supply sufficient food to meet more than 60 per cent of the food requirements of the 1,200 native inhabitants.

---

* Dr. David I. Blumenstock is Pacific Area climatologist, U.S. Weather Bureau; Dr. F. R. Fosberg is botanist, U.S. Geological Survey; and Mr. Charles G. Johnson is geologist, U.S. Geological Survey.

The re-survey has revealed that although the effects of the typhoon are still evident on all islets, there have been very significant changes. In virtually all locations studied the rubble bar on the ocean reef of the eastern islets has moved landward. In several places it has joined the main body of land ; in others the rubble has spread out to form boulder tracts on the reef-flat ; and in still others the bar remains separated from the main land body, but 20–50 yd. closer to it. New bars on the lagoon side of the eastern islets seem largely to have remained intact, though doubtless their form has changed somewhat. Gravel sheets still lie across the islets, but are being invaded by vegetation. In most places the vegetation has made considerable recovery. Culturally, re-planting of coconut palms has been virtually completed, some breadfruit have been replanted and the recovery of damaged or partially destroyed trees has greatly improved the local food supply. These three aspects of change—geomorphic, vegetational and cultural—will be discussed at somewhat greater length, and some comment made on renewal of the soil.

Geomorphic changes. The most conspicuous geomorphic change since Typhoon *Ophelia* has been the migration, removal or spreading out of nearly all of the rubble bars that were formed by the typhoon along the middle of the ocean reef on the eastern side of Jaluit. Remnants of the bar that do remain are little changed, except that there has been locally a slight increase in height by addition of gravel or decrease in height by removal of gravel and consequent slumping of the boulders and slabs that comprise the major part of the bars. Where the rubble bars have been removed, broad, low tracts of imbricated slabs and boulders remain. In a few places even these have been removed and the reef-flat is essentially bare. The materials derived from the bars now form gravel and rubble ridges or ramparts along the seaward edges of the islets, as was the situation before the typhoon.

Less change was noted in the off-shore bars along the lagoon side of the eastern reef. Essentially all the bars remain intact and show little or no loss of material or slumping. On the contrary, the bars have been enhanced in some places by addition of fresh gravel tossed up by waves in the lagoon.

Within the tide zone, scour pits and channels cut through sand or poorly consolidated sediments have become partly filled and will probably fill more. Little change could be seen in scour pits and channels at heights above the effect of tides and waves ; these are likely to become permanent irregularities in the topography until the next typhoon.

The general condition throughout Jaluit resulted from a re-adjustment of the shore-lines and bars created by the typhoon back to alignments of equilibrium approximating those that existed before the typhoon. Gravel and rubble bars, the situations of which are not too much at variance with the normal regimen of the waves, currents and winds, will probably remain in place long enough to become sufficiently indurated to be permanent reminders of Typhoon *Ophelia*. Other features that are likely to be more or less permanent are the gravel sheets that covered large seaward land areas of the windward islets, the scour channels, and the tidal ponds between the lagoon gravel bar and the islets.

Vegetation and soils. Superficially, the aspect of the vegetation has changed strikingly in the two and a half years since the 1958 survey.

Most of the areas that were then barren expanses of coral rock and gravel are now green and have a luxuriant, though low, herbaceous and shrubby vegetation. These areas, swept by both wind and high waves, still have little that could be called soil in the ordinary sense, as the fine material was generally washed out by the typhoon waves. Locally, only a strictly pioneer vegetation has become established, or even none at all. Elsewhere the pioneer species have largely been smothered by aggressive secondary vegetation.

Areas which were affected only by wind, rather than wind plus water, have, in many places, produced a dense low forest or tall scrub in which *Pipturus argenteus* is a principal component.

Estimation of the degree of recovery of the vegetation has been complicated by the fact that, during the extensive re-planting of coconuts, the brush has been largely cleared out once ; therefore the present vegetation represents recovery from this operation, as well as from the effects of the typhoon. The pre-typhoon vegetation was completely dominated over most islets by coconut and breadfruit groves and plantations. As pointed out in the 1958 article, these were in a large measure damaged or destroyed. Although re-planting, at least of coconuts, has been extensive, the planted seedlings have not yet assumed an important role in the vegetation, and it will be certainly 10–15 years before the more thoroughly devastated areas can be expected to resume their former densely forested appearance. Further, unless there is a greater emphasis on breadfruit planting than at present, the resulting forest will be far more dominated by coconut palms than was the case before the typhoon. Minor vegetation types, such as mangrove, *Pemphis* forest, beach ridge scrub and scrub forest and the *Pisonia* forest on small protected islets are mostly already beginning to resume their former aspects, and only need to grow up to their former stature to be much as before.

Much information was gained on the mode of adaptation of some of the important atoll and strand species to survival and recovery from typhoons. For example, of the tree species, *Pandanus*, *Cocos*, *Bruguiera* and *Pipturus* have largely replaced themselves by seedling reproduction, whereas *Pemphis*, *Artocarpus*, *Terminalia*, *Pisonia* and *Cordia* have conspicuously sprouted from the remains of plants damaged by the typhoon. *Scaevola* and *Tournefortia*, while sprouting abundantly from old stumps, have also appeared from seed in great profusion.

The difference in soils between wave-swept and non-wave-swept areas is conspicuous. In the former, whether the soils were buried by gravel or removed, little new soil development has taken place beyond the addition of some litter on the surface and some humus and roots in crevices and interstices. On the areas still retaining the original soil, the effect of the typhoon has perhaps proved beneficial. In places, large quantities of organic debris were added to the soil and much of this has decomposed; also, since the typhoon, the people have shown very little tendency to resume the previous burning of vegetable trash but rather they now allow it to rot. Consequently, many of the soils of the non-wave-swept islets are, at present, in excellent condition as coral atoll soils go, and are loose, friable, dark and rich in organic matter even when gravelly. This state of affairs may well continue so long as burning is not resumed. On most of the wave-swept areas soil amelioration will be much slower, depending on the weathering of gravel, addition of organic matter from root growth and leaf fall, and carrying in by wind or waves of sand- and silt-sized materials.

Cultural changes. We also noted marked changes in the cultural scene. Dwellings and other structures in the villages had all been repaired or rebuilt. Village walks had been cleared, and several have been bordered with stones. Where before there were none, ornamental plants now grow in neatly arranged gardens in front of several dwellings; and in many places coral debris has been cleared from garden areas and stacked in mounds nearby. The debris from fallen trees has been cleared from large parts of the inhabited islets, but not from the uninhabited ones.

There are now many more outrigger canoes than there were in April 1958. No count was made of these, but several boats were seen in each of the five villages visited (Jabor, Majuriruk, Pinlep, Jaluit, Imroj). None of these canoes exceeds 15 ft. in length, but we were told that they meet the needs of the natives for transport and fishing in the lagoon and at distances up to a few miles out to sea.

Among the subsistence crops that are now thriving and are being used are breadfruit, pandanus, pumpkins, bananas and sweet potatoes. The last two are especially widely grown. Coconuts remain the chief subsistence crop despite the large number of trees destroyed in the typhoon. In contrast, taro, which was an important crop on Pinlep Islet prior to the typhoon, is now only just beginning to be raised again.

The administration has sponsored and assisted with a wide-spread programme for the re-planting of coconut palms to provide a cash crop in the years ahead. This programme has been completed on all but the eastern islets, where it has almost been completed. At present, however, there is little or no copra produced for export, and the principal exports are trochus shell and handicrafts, neither of which provides a substantial cash income.

OBITUARIES

Prof. D. Cordier

Physiologists throughout Europe will have learnt with sorrow of the death in October of Prof. Daniel Cordier in his sixtieth year. From 1946 he had held the chair of general physiology in the University of Lyon, but during the war years he was a well-known figure in Cambridge, where he conducted researches on chemical warfare for the French Forces under General de Gaulle.

Before the Second World War he had been in charge of the research station at Le Bouchet as director of the Physiological Laboratory under the Ministère de l'Armement, and in June 1940 he was one of the party of French scientists brought to England by the Earl of Suffolk to carry on their war work for the Allies. He and Madame Cordier lived in Cambridge until 1945, accepting exile with an unshaken faith in the outcome and making many friends.

Trinity College was particularly fortunate in having Prof. Cordier as a genial member of its society. His sturdy figure became a symbol of the French resistance, the colleagues who came to consult him were welcome guests at the high table, and his regard for the College added to the pleasure of his company.

He had an extensive knowledge of pulmonary and renal physiology which was of great assistance to all who worked in the Physiological Laboratory, and his own work on traumatic shock and intoxication showed his experimental skill and made a valuable contribution to war-time research.

After his return to France he continued and extended his work on more general lines, studying the effects of different forms of shock in a wide range of animals and dealing particularly with the disturbance of glycogen metabolism in the heart and liver. He became secretary-general of the Association des Physiologistes de Langue Française and the French representative in the International Union of Physiological Sciences. He will be greatly missed by the many colleagues who knew him in England and had the pleasure of seeing him again established in his own laboratory after the War.

Adrian

Mr. Henry Braid Irving, O.B.E.

Henry Braid Irving died in hospital at Stoke Mandeville, Bucks., on January 12 at the age of seventy-one after a lifetime devoted mainly to aerodynamic research. He was educated at the King's School, Chester, and at the Manchester College of Technology, and this was followed by four and a half years of practical and design experience in marine and general engineering on the Clyde.

He commenced his aerodynamic researches at the National Physical Laboratory in 1914, and his great contribution to the advancement of aeronautical science is indicated by the publication of more than sixty papers in the next twenty-five years. They cover a wide field, including airships, seaplanes, kite balloons, radiators, stress calculations and buffeting in addition to aeroplane stability and control problems and the spinning of aeroplanes. He is best known for his work on these last subjects, being the first to suggest the use of the slot for the improvement of lateral control in August 1922, a subject on which he published several papers; this was later recognized by the award of the Charles Wakefield Gold Medal by the Royal Aeronautical Society in 1929. The aerodynamic balancing of controls was aided by his proposal for a shrouded nose balance in November 1939, and a practical method of balancing split flaps published in May 1936 is known by his name.

In 1939 Irving was transferred to the Royal Aircraft Establishment and later became assistant director of scientific research (air) at the Ministry of Supply until his retirement in 1954. While at the Ministry he was responsible for initiating in 1950 researches on the reduction of the noise from jet engines. He wrote several papers on noise, was a consultant on this subject to the Ministry during 1954–57 and afterwards to the firms of Bristol-Siddeley and Westland Aircraft. He had also been chairman of the Noise Research Committee of the Aeronautical Research Council and a member of several of its other committees.

He was made a Fellow of the Royal Aeronautical Society in 1932, and was a founder member and chairman of the Man-powered Aircraft Committee of the Society, the committee which has fostered the growing interest in Britain in man-powered flight. Due to his personal efforts and his published articles, the prospects of man-powered flight in the near future has been enhanced.

Henry Irving was a man of great personal charm, kindness and sincerity, and he was an inspiration to all those who came in contact with him. He leaves a widow and two daughters. J. L. Nayler

Mr. W. A. Kay

William Alexander Kay, who died in January, was a prince of laboratory stewards whose fame spread far beyond the Physics Laboratory at Manchester in which he spent the whole of his working life. He started there as a laboratory assistant in 1894, and became steward in 1908, serving successively under Sir Arthur Schuster, Lord Rutherford, myself and Prof. P. M. S. Blackett. He was Rutherford's chief helper in the great days of his Manchester researches. In recognition of his services to the University he was made an honorary M.Sc. in 1946, and the University staff service centre is named after him.

He was an excellent steward and brilliant at devising experiments and demonstrating them in class. When Rutherford left Manchester in 1919 he invited Kay to go to Cambridge with him, but Kay could not bring himself to leave his native heath. How fortunate this was for the very inexperienced young professor who succeeded Rutherford can only be realized fully by myself. A great change has come over laboratories since those days, with their large establishments of secretaries, accountants, research and lecture room assistants and mechanics. Kay combined all these roles, and those of guide, philosopher and friend as well.

But it is not for his skill and his unflagging zeal that he will be chiefly remembered. His integrity, discretion, wisdom, warmth, and combination of modesty with a sturdy independence made a deep impression on all who knew him. The comparison may seem fanciful, but it is one which I have often made in my own mind. His personal qualities endeared him to us in much the same way that Michael Faraday's personality endeared him to his contemporaries. W. L. Bragg

NEWS and VIEWS

Dr. Jerome B. Wiesner

President Kennedy has appointed Dr. Jerome B. Wiesner to succeed Dr. George B. Kistiakowsky as special adviser for science and technology to the President. Dr. Wiesner has been on the staff of the Massachusetts Institute of Technology since 1946, being appointed to the grade of professor in the Department of Electrical Engineering in 1950. During the same period he carried simultaneous responsibilities at the Institute for the research laboratory of electronics, of which he became director in 1952. Born in Detroit, Michigan, in 1915, he went to the nearby University of Michigan, earning the degrees of B.S., M.S., and Ph.D. in engineering. During his twenties, he sampled a variety of occupations, ranging from a broadcasting station to the Library of Congress (as chief engineer). Thereafter he spent three war years at the Radiation Laboratory, Massachusetts Institute of Technology, followed by a year at the Los Alamos Scientific Laboratory during 1945–46. In addition to his academic and research posts, he has acted as consultant to industrial firms. Dr. Wiesner's research and scientific interests have been principally in the fields of acoustics, electronics, radar and theory of communications. Among his achievements was the development of the 'scatter' communication system, making possible the extensive distant early warning line spanning the northern perimeter of the American continent. In recent years, his interests in the international political problems of science have widened, stimulated in part by membership of President Eisenhower's scientific advisory committee, by his appointment in 1958 as staff director of the U.S. delegation to the Geneva Conference on means of reducing the dangers of surprise attack, and by his attendance at several Pugwash Conferences.

Machine Tool Industry Research Association :
Mr. A. E. de Barr

Mr. A. E. de Barr, who has been appointed the first director of the Machine Tool Industry Research Association, has had a distinguished career in industrial research. Born in 1918, he graduated with first-class honours in physics from the University of Leeds in 1939 and, after a short period of postgraduate research, proceeded to the Mine Design Department of the Admiralty. He remained with the Admiralty until the end of the War and then joined the firm of Joseph Sankey and Sons, Ltd., as research superintendent (physics). He transferred to the Guest, Keen and Nettlefold group of companies when the Research Laboratories of Sankey's became the Central Research Laboratories of the group. In 1950 he accepted the position of leader of the Physics Division of the Research Laboratories of Elliott Bros. (London), Ltd., where he was responsible for the establishment and development of physics, chemistry and metallurgy laboratories. Mr. De Barr joined the staff of the Shirley Institute, Manchester, in November 1953 as head of the Spinning Department, where his main contribution has been in the application of physical concepts to fibres and yarns and the engineering improvement of the spinning process. He is the author of a number of scientific papers on physical and engineering subjects, a Fellow of the Institute of Physics and has for many years played an active part in the development of technological education. The new Research Association is to be congratulated on getting as its first director a man of outstanding scientific ability, who brings to it also an appreciation of the problems of industry, and particularly of engineering industry, at a time when the machine tool industry in Britain looks to be moving into a new phase of production techniques.

Pure Mathematics at Swansea :

Prof. R. Wilson

PROF. R. WILSON, head of the Department of Pure Mathematics in Swansea, retires in September 1961 after being a member of the staff of the University College of Swansea (University of Wales) for forty years. Educated at Bradford Grammar School and Queen's College, Oxford, where he was a Hastings Scholar, he served in the First World War before graduating in 1921. In the same year he was appointed an assistant lecturer in the Department of Mathematics in Swansea, a year after the foundation of the College. He became a senior lecturer in 1929 and professor from 1942. His published research papers cover a variety of topics in mathematical analysis and those on the classification of singularities of functions of a complex variable are perhaps best known. He spent a year in Cambridge as a Leverhulme Research Fellow during 1938–39, and in 1955 was awarded an Oxford D.Sc. Three times dean of the Faculty of Science, and for his last five years the senior professor in Swansea, Prof. Wilson has served at one time or another on a large number of the committees of the College and of the University of Wales, and has often provided a powerful stabilizing influence, in days of rapid expansion and frequent change, using his long experience to help preserve continuity with the earliest days of the youngest of the Welsh university colleges.

Prof. J. D. Weston

DR. J. D. WESTON, reader in mathematical analysis in the University of Durham at King's College, Newcastle upon Tyne, has been appointed to succeed Prof. Wilson. Among his responsibilities will be that of organizing all the post-intermediate teaching of mathematics to applied scientists in the College, and it is of interest in this connexion that Prof. Weston first graduated by taking a first-class honours degree in engineering in London in 1939. As a practising radio development engineer, he was on the staff of Standard Telephones and Cables, Ltd. After gaining a London B.Sc. in mathematics (1944) and Ph.D. in engineering (1946), he was for a short time lecturer in mathematics at the Woolwich Polytechnic and later lecturer in the Mathematics Department of the University of Sheffield until 1949. He then moved to King's College, Newcastle, where he became a senior lecturer in 1958 and was appointed to a personal readership in 1960. During the academic year 1959–60, he held a visiting associate professorship in the California Institute of Technology, and in 1960 was awarded a London D.Sc. Prof. Weston has a distinguished research record and an international reputation as a functional analyst. His published work has been concerned mainly with the properties of certain topological spaces, including linear spaces, and more recently with an elegant treatment, based on convolution algebra, of that part of distribution theory from which a rigorous account of the Heaviside operational calculus can be developed.

Re-organization in the U.K. Atomic Energy Authority

CHANGES in the organization of the United Kingdom Atomic Energy Authority are being made, as the result of recommendations of the Select Committee on the Industrial Group which reported in July 1959. Sir William Penney has been appointed deputy chairman, with primary responsibility for scientific and technical co-ordination throughout the Authority. The work of designing and developing nuclear reactors will be concentrated, to the greatest possible extent, in one group of the Authority. The major development facilities required for this purpose will be under its control. The structure of the Development and Engineering Group will be modified for this purpose. It will be re-named the Reactor Group and will be responsible for the design and development of reactors, and for relations in this field with industry in Great Britain and with overseas countries. The Winfrith Research Establishment, which has responsibilities in the same field, will be transferred from the Research Group to the Reactor Group. The existing responsibilities of the Development and Engineering Group for the design and construction of plant, works and buildings will be transferred to a new Engineering Group, which will also take over from the Production Group its responsibilities for the design and inspection of fuel elements for production purposes. Apart from the transfer of the Winfrith Research Establishment, the structure and responsibilities of the Research Group remain unchanged. The Weapons Group is unaffected by the new arrangements.

National Lending Library for Science and Technology

IN a written answer in the House of Commons on February 16, the Parliamentary Secretary for Science, Mr. D. Freeth, said that from April 1957 until the end of March 1961, expenditure on the National Lending Library for Science and Technology was estimated at £904,000, including the capital cost of adapting the buildings at Boston Spa, Yorkshire. The net cost of the existing Library unit in London would be about £272,000 in the current financial year, and after the move to Boston Spa was completed and the Library was fully operational, at the end of 1962, the annual cost would be about £315,000. No direct expenditure had yet been incurred on the National Reference Library for Science and Invention.

The Health Programme in India

THE November issue of *Science and Culture* (26, No. 5) contains an article outlining the health programme of the Third Five Year Plan in India, and also a discussion of the proposals by Dr. A. N. Khosla, delivered to the Health Panel of the Planning Commission. Of the 300 crores of rupees allocated for health, 80 crores are for water supply and sanitation, 50 crores for primary health units, hospitals and dispensaries, 92 crores for control of communicable diseases, 38 crores for education and training and 25 crores for family planning. The shortage of medical personnel is a grave problem; there are about 71,000 doctors in India, 25 per million in rural areas and 800 per million in urban areas, while the present 55 medical colleges have an annual intake of 5,000 and train about 2,800 graduates each year. The position regarding women doctors is particularly unsatisfactory. It is suggested that it is not suitable to increase the number of medical colleges at present, but that the resources of the Plan could be more profitably used in raising the standard of teaching, providing more equipment and space in the hospitals and laboratories and increasing the staff of qualified teachers in existing institutions. The total allocation of Rs.300 crores is regarded as inadequate, and besides a determined effort to eliminate the adulteration of food, a bolder policy in regard to water supply and sanitation is urged, and expansion of the existing scheme for eradication of endemic goitre by the supply of iodinated salt is recommended to cover the whole of the endemic belt. The public health laboratories envisaged should be provided with free diagnostic services for the public.

Information on Translations

A NEW international information office has been jointly established by Euratom, the U.S. Atomic Energy Commission and the U.K. Atomic Energy Authority in Brussels. Called 'Transatom', it is intended to act as a clearing house for information on the translations of nuclear literature available from a variety of organizations. It publishes monthly the *Transatom Bulletin*, which lists in the style of *Nuclear Science Abstracts* translations at present available of articles, with source and price. It also lists forthcoming translations as well as translations of whole journals. In addition to this service, 'Transatom' is assembling a master file of translations of interest. This file may be consulted by subscribers to the *Bulletin*. The first issue of the *Bulletin* is dated December 1960 (Pp. 80. 50 francs; 1 dollar. Bruxelles: Euratom, Transatom Service, 51 rue Belliard, 1960). The majority of the translations listed are from Russian and Japanese journals, and the language of the translation is English, French or German. Further information may be obtained from Euratom, Transatom Service, 51 rue Belliard, Brussels.

International Natural History Research

YOUNG naturalists all over Europe have been carrying out a survey of the arrival and departure of the swift and the flowering time of the wood anemone. Their report for 1959 has been issued by the International Youth Federation for the Study and Conservation of Nature. The first swift was reported in Holland on April 18, and the 'last first' in Finland on June 7. On the return migration the swifts disappear from the more southerly breeding localities before they have left those in Scandinavia. The first wood anemone came into bloom in Holland on March 19, and the 'last first' in mid-Finland on May 18. Many Nature clubs in Britain are associated with the Federation through the British Co-ordinating Group, but there is no reason why young naturalists in any society should not participate. The programme for 1961 will follow the plan as used in previous years. Introductory notes and duplicated recording sheets will be available very soon and the work will begin in the early spring. Recording for the wood anemone will be over by about the beginning of April, but recording for the swift will continue until the end of the summer. For the swift, the dates for the arrival of the first individual and the main flock will be required, details about nesting sites, numbers of young birds in selected nests and also the dates at which the birds left the area in the autumn. For the wood anemone, information will be required about the habitat, abundance of plants at a given locality, details of the phenology and also counts of the number of petals on individuals in a random sample. Information and recording sheets will be available from the secretary of the *Naturalist*, Derek S. Davis, 56 Altmore Avenue, East Ham, London, E.6.

The National Art Gallery and Dominion Museum, New Zealand

THE report of the Board of Trustees of the National Art Gallery and Dominion Museum for the year ended March 1960 discloses a year of activity in many directions (Pp. 30. (H. 21.) Wellington: Government Printer, 1960). Temporary exhibitions included an unusual one of Czechoslovakian Truka puppets. The re-appointment of an educational officer has proved of great value to this side of the gallery work. In the Museum section some valuable field work has been undertaken including natural history investigations in twelve outlying islands in Cook Strait and the recording of Maori occupation sites in the Wellington District. An impressive list of publications by the staff is an indication of the value of research as one of the functions of a museum.

Coronary Artery of the Portuguese East African

MYOCARDIAL infarction is generally recognized to be the consequence of thrombosis in a diseased coronary artery. While not all diseased arteries promote thrombosis, the frequent association of thrombosis and coronary disease has led to the view that perhaps an understanding of the factors promoting disease of the coronary artery may assist in preventing the high incidence of myocardial infarction in the Western world. In searching for aetiological factors, attention has been focused largely on the age group in which coronary disease is most likely to declare itself clinically. Equally important, but less well known, is the observation that the coronary artery is unique in that regressive changes are initiated early in life, and even within a month after birth. Some of these regressive changes, if accentuated, are unmistakably similar to those which have been described in advanced sclerosis, with and without atherosis of the coronary artery.

During the past twenty-four years, several reports have directed attention to the rarity of coronary thrombosis in the indigenous peoples of different parts of Africa. While advanced coronary disease has been described in the African, it is believed that the disease is less common, milder in character and declares itself later than in the white races of Europe and the United States of America. In view of this marked difference in susceptibility to coronary artery disease of white people and Africans, and of the expressed opinion that the regressive changes occurring in the coronary artery soon after birth may be linked to the pathogenesis of coronary disease, Joseph Gillman, Christine Gilbert and Manuel D. Prates have considered it desirable to examine the coronary arteries at different periods of life of an African population in which coronary artery disease is known to be uncommon (*S. Afr. J. Med. Sci.*, 25, Nos. 2 and 3; September 1960). They have endeavoured to record: (1) the histological reactions observed in the coronary arteries at successive age periods from birth to more than sixty years in the Portuguese East African in Lourenço Marques; (2) to type the reactions in a way which will make future comparison between these and reactions in the coronary arteries of peoples elsewhere in the world; and (3) to assess the significance of these reactions for the development of severe coronary artery disease and thrombosis.

Distribution of British Reptiles and Amphibians

A PAPER by R. H. R. Taylor on the distribution of Reptiles and Amphibians in the British Isles was first published in the *British Journal of Herpetology* in June 1948 (1, No. 1). In this paper, a complete record of the occurrence of the different species in the British Isles and Channel Isles was presented. It is proposed to re-write the paper and include records up to the end of 1960. To obtain a complete and accurate picture of the present distribution, up-to-date records from all areas are required. For 40 or 50 years there have been no published records of even the commonest species from a number of vice-counties. Lieut.-Colonel Taylor is anxious to obtain information about the following species: *Anguis fragilis* (slow worm); *Lacerta vivipara* (viviparous lizard); *Lacerta agilis* (sand lizard); *Coronella austriaca* (smooth snake); *Vipera berus* (viper or adder); *Natrix natrix* (grass or ringed snake); *Triturus helveticus* (palmate newt); *Triturus cristatus* (great crested or warty newt); *Triturus vulgaris* (smooth newt); *Bufo calamita* (natterjack); *Bufo bufo* (common toad); *Rana temporaria* (common frog); *Rana ridibunda* (marsh frog); and *Rana esculenta* (edible frog). The records should show the year the species were observed and the locality. Any data should be sent to Lieut.-Colonel R. H. R. Taylor, The Studio, Belchamp St. Paul, Sudbury, Norfolk.

Dependence of Photosynthesis on Temperature in Higher Plants

IN a paper entitled "Studies of Climatic Ecotypes in Higher Plants: the Temperature Dependence of Apparent Photosynthesis in Different Populations of *Solidago virgaurea*", O. Bjorkman, C. Florell and P. Holmgren (*Kungl. Lantbruckshögskolans Annaler*, 26, 1; 1960) present results of a study of the temperature dependence of apparent assimilation in plants from different populations. Clonal material was obtained from different climatic zones, ranging from Skåne in south Sweden to Finmark in north Norway, and grown in a phytotron in chambers maintained at three different climates (alpine, continental and maritime). The climates reproduced in the chambers were based on 20-year meteorological records. Some populations were also grown under constant day and night temperatures (18° C. and 8° C. respectively) with a photoperiod of 18 hr. The apparent photosynthesis of intact plants was measured. The ecotypes were found to vary in chlorophyll content, but these differences were not correlated with values of apparent photosynthesis. The optimum temperature for photosynthesis of plants from a maritime habitat in south Sweden was 20° C., irrespective of the climate in which they were grown. Plants from an alpine region in north Norway, on the other hand, with a few exceptions, had an optimum temperature of 16° C. in all three climates. By contrast plants from an inland region of central Sweden were more variable. The results show a good correlation with the temperature conditions during the growing season of the three localities, and there appears to be a physiological adaptation to the temperature conditions which is under genetical control. With plants grown under constant day and night conditions some differences were found, but not as obvious as those in the climate series.

Synoptic Auroral Maps

AT the Antarctic Division of the Department of External Affairs, Melbourne, Major F. R. Bond and Dr. F. Jacka have undertaken the compilation of synoptic maps showing, at quarter hourly intervals, the plan position of auroras observed in the southern hemisphere during the International Geophysical Year. So far, only the data from Australia and the antarctic stations of Australia, France, Belgium and New Zealand have been plotted. With such maps it has been possible to make an estimate of the location of the isoaurore of maximum frequency of occurrence of auroras (*Aust. J. Phys.*, 13, 610; 1960), and to make a general study of the development of auroral displays and associated magnetic disturbance on the equatorwards side of the auroral zone (*Aust. J. Phys.*, 13, 477; 1960). But on some occasions of intense magnetic disturbance ($Kp = 8$ or 9) the aurora, for many hours, takes the form of an extensive red 'diffuse surface' over polar-cap stations. At present the synoptic maps are not complete enough to establish the extent of these 'surfaces' nor are any measurements of their height available. However, it is thought that on these occasions the electric current which gives rise to magnetic disturbance is in the nature of a continuous sheet rather than of filamentary structure as seems usual (*Aust. J. Phys.*, 14; March 1961). G. Weill and Mlle. S. Huille, of France, and Mlle. P. Doyen, of Belgium, have co-operated with Messrs. Bond and Jacka in the task of compiling these maps, and the co-operation is now invited of other workers concerned with the study of southern hemisphere auroral data.

Engineering Aspects of Lubrication

THE Imperial College of Science and Technology is organizing a short postgraduate full-time course on "Engineering Aspects of Lubrication" during May 1–19. This will be an intensive course covering the subject from the engineering aspect, including theories of fluid film, thin-film lubrication, wear of lubricants, lubricating materials, the properties of natural and synthetic oils, etc. The number of participants for the course will be limited to thirty-two and the fee will be 25 guineas. Further information can be obtained from the Registrar, Imperial College of Science and Technology, London, S.W.7.

The British Institute of Radiology: Annual Congress

THE annual congress and exhibition of the British Institute of Radiology is to be held jointly at the Central Hall and Church House, Westminster, London, W.C.1, during April 26–28. A number of symposia are to be included in the programme: "Localization using Physical Devices, Radioisotopes and Radiographic Methods" (April 26, at the Central Hall); "The Age Factor in the Susceptibility of

Man and Animals to Radiation" and "Planning of New Radiotherapy Departments" (April 27, at the Central Hall); "Planning of New Diagnostic Departments" and "Radiological Assessment of Bone Density" (April 27, at Church House); "Recent Developments in Linear Accelerators for Therapy" (April 28, at the Central Hall); "Industrial Developments in Diagnostic Equipment" (April 28, at Church House). The Silvanus Thompson Memorial Lecture will be given by Sir Bernard Lovell on "The Condition of Outer Space", at the Central Hall on the evening of April 26. Two exhibitions are also being arranged, one at the Central Hall and the other in the Hoare Memorial Hall, Church House. Further information can be obtained from the General Secretary, British Institute of Radiology, 32 Welbeck Street, London, W.1.

The Night Sky in March

Full moon occurs on Mar. 2d. 13h. 35m. U.T. and new moon on Mar. 16d. 18h. 51m. The following conjunctions with the Moon take place: Mar. 1d. 14h., Regulus 1° N.; Mar. 12d. 20h., Saturn 3° S.; Mar. 13d. 00h., Jupiter 3° S.; Mar. 22d. 04h., Aldebaran 0·2° S.; Mar. 24d. 18h., Mars 7° N.; Mar. 28d. 21h., Regulus 1° N. There will be a partial eclipse of the Moon on March 2, invisible at Greenwich. Mercury is too close to the Sun for observation. Venus is an evening star, favourably placed for observation. Venus sets at 21h. 50m., 21h. 35m. and 20h. 30m. on March 1, 15 and 31, respectively, about four hours after the Sun at the beginning of the month. Venus attains its greatest brilliancy on March 5, when its stellar magnitude is −4·3. During the month its distance from the Earth decreases from 44 to 27 million miles and the visible portion of the apparent disk from 0·315 to 0·045. Mars sets at 4h. 20m., 3h. 40m. and 2h. 55m. at the beginning, middle and end of the month, respectively. Mars is conveniently situated for observation. It is at a distance of 104 million miles from the Earth on March 15, when its stellar magnitude is + 0·6. Jupiter and Saturn are too close to the Sun for easy observation. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Mar. 21d. 21h. 11·5m., γ Tau. (*D*); Mar. 29d. 23h. 45·5m., 59 Leo. (*D*). *D* refers to disappearance. The spring equinox occurs on Mar. 20d. 21h.

Announcements

Lord James of Rusholme, High Master of Manchester Grammar School since 1945, has been appointed as the first Vice-Chancellor of the University of York; he is expected to take up his duties early in 1962. Lord James, who is a science graduate of Oxford, was a member of the University Grants Committee during 1949–59.

Dr. Christopher E. Barthel, jun., assistant director of the Armour Research Foundation of the Illinois Institute of Technology, has been appointed to the Office of Special International Programmes of the National Science Foundation, Washington, where he will be programme director for foreign science activities.

Mr. R. P. Newman has been appointed head of the Members' Service Department of the British Welding Research Association in succession to Mr. P. H. R. Lane, who has been appointed director of research of the Drop Forging Research Association. Mr. T. R. Gurney will succeed Mr. Newman in charge of fatigue researches at the British Welding Research Association.

Dr. C. G. Hunter, formerly professor of physiological hygiene, School of Hygiene, and associate professor, Banting and Best Department of Medical Research, University of Toronto, has been appointed director of the Tunstall Laboratory, near Sittingbourne, Kent, recently opened by 'Shell' Research. The laboratory will be concerned with the possible effects on man and other vertebrates of contact with products being developed by the Royal Dutch/Shell Group of Companies, and has four divisions, dealing with pathology and pharmacology, physiology, chemistry and biochemistry, respectively.

The Ninth German Plastics Convention is to be held in Berlin during April 12–14. Further information can be obtained from the Arbeitsgemeinschaft, Deutsche Kunststoff-Industrie, Karlstrasse 21, Frankfurt am Main.

The Plant Phenolics Group is holding a meeting on "The Importance of Plant Phenolics in Industry" at Cambridge during April 10–12. Further information can be obtained from the Honorary Secretary, Low Temperature Research Station, Downing Street, Cambridge.

The West German Starch Research Station, Detmold, is organizing an international conference on "Starch" at the Cereal Research Association, Detmold, during April 26–28. Further information can be obtained from W. Kempf, Cereal Research Station, P.O. Box 23, Detmold, West Germany.

The National Vegetable Research Station Association is holding a members' day on March 1. The subject of the day's programme will be "Soil Physical Conditions affecting Plant Growth". Further information can be obtained from Mr. G. Lesson, National Vegetable Research Station, Wellesbourne, Warwick.

The annual conference, organized by the Stress Analysis Group of the Institute of Physics and Physical Society, will be held in the University of Southampton during April 24–27. The topic for the conference will be "The Mechanics of Rupture". Particulars of the meeting can be obtained from Mr. L. Lawrence, Institute of Physics and Physical Society, 47 Belgrave Square, London, S.W.1.

The Easter congress of the Universities Federation for Animal Welfare is to be held at the University of Liverpool Veterinary Field Station, Leahurst, Neston, Wirral, Cheshire, during April 10–14. The programme will include lectures, discussions and visits connected with the Federation's work and with animal welfare in general. Inquiries should be sent to U.F.A.W. (Easter Congress), 7a Lamb's Conduit Passage, London, W.C.1.

The anniversary meeting of the Chemical Society is to be held in Liverpool during April 11–14. The meeting will include two concurrent symposia, namely, "Developments in the Chemistry of Boron Compounds" and "Some Aspects of the Chemistry of Natural Products", and also a number of visits. The meeting, other than the annual general meeting (April 13), will be open to the public. Further information can be obtained from the General Secretary, Chemical Society, Burlington House, London, W.1.

WESTERN DEPENDENCE ON OIL

A WARNING that Britain's dependence on oil has become "potentially dangerous to our national economy" is made by the 11,000 strong Association of Scientific Workers in a 'policy statement' in a new publication entitled *A National Fuel and Power Policy**.

The recommendations in this statement are put forward in the form of a twelve-point plan that has as a main objective improved co-ordination and development of the national resources of fuel and power. The objectives are worthy ones, and are set out in an attractive manner with some sound supporting arguments, but some of the means to be employed in the plan are open to question on the grounds of practicability.

The first point made is that the efficiency of the production of coal should continue to be improved with the view of making coal cheaper in real terms. For this purpose increased expenditure on scientific research is rightly regarded as necessary, but, in the subsequent recommendations, difficult and almost intangible problems are raised as to the maintenance of markets over fixed periods, the subsidizing of specific uses of coal, the 'firm basing' of the generation of electricity on coal and back-pressure generation by industry and much additional planning. Several of the suggestions made for controlling the balance of fuels and the types of appliance installed embody a measure of compulsion either by legal requirements or by discriminatory taxation. There is nothing intrinsically against this, though it is clearly contrary to the present Government's policy. Attempts to control markets in the manner suggested are not necessarily in the national interest, nor do they actually work out in the manner intended in practice. The back-pressure generation of power in industry is only economical if the individual circumstances of the case in point are favourable. Each set of circumstances becomes almost a law unto itself, and sweeping decisions as to their application in general cannot be made.

As regards the recommendation for the formation of a National Coal Chemical Board, it is not clear what advantages would accrue from yet another national board in a relatively small field of activity.

Concerning the needed improvements in research and development in the mining, utilization, and marketing of coal, controversy may well arise. Thus it is perhaps surprising to read that it may be necessary to abandon the conception of the British Coal Utilization Research Association as the National Coal Board's agent in the field of coal utilization, for it seems perfectly clear that the National Coal Board has always interpreted literally its remit under the Nationalization Act as "making supplies of coal available, of such qualities and sizes, in such quantities and at such prices, as may seem to them best calculated to further the public interest in all respects . . ."; in other words, utilization has not been the National Coal Board's responsibility under the Act; in fact the support given to the British Coal Utilization Research Association has been somewhat incidental. In point of fact this support has approximated to £140,000 per annum since nationalization, the overall income of the British Coal Utilization Research Association in 1959 being £427,000. The Association is thus operating on a much broader front than is implied in the statement of the Association of Scientific Workers. This research work covers contract work for the Atomic Energy Authority as well as that for the Ministry of Power. As regards the latter, the contract work on the slagging gasifier, as well as other features of the research programme, received commendation in the recent report of the Wilson Committee on Coal Derivatives. Further, the Association's real potential for work in coal utilization on a broad front was indicated, given adequate financial support.

It is not realized fully, perhaps, by the public that scientific work on the winning, preparation and use of coal requires an array of top-level scientists and technologists not yet even contemplated; moreover, to attract such personnel to-day to an industry in disfavour with the public mind will necessitate a radical change of approach. The expenditure on research by the National Coal Board, as given in the Wilson Report, was £2,427,300 in 1959, its turnover, £850 million, that is, approximately 0·29 per cent.

Cogent criticism is devoted to the world role of the oil industry, which is regarded as an international one dominated by a few large producers with price-fixing arrangements "typical of a cartel". "In Western Europe the price of oil and refined products has been below internationally arranged prices", the statement declares, and this increasing dependence in Western European countries on oil has made them vulnerable to price increases which would "adversely affect our position in world markets since fuel costs are a significant part of production costs". This may be true, but the question is not answered as to whether a manufacturer who finds the use of oil more economical than alternative fuels, mainly the derivatives of coal, should hold off conversion of his plant to oil because of this possibility. It is, however, evident from the arguments put forward that the challenge of oil can mainly be met by a substantial increase in technological activity in respect of coal.

A point of considerable interest is made as regards the inflexibility of the fuel oil/petrol ratio of refinery production in Britain. Thus Britain imports 73 per cent of its oil as crude oil, and this is refined so as to yield 27 per cent motor- and aviation-spirit, and 43 per cent fuel oil and other products such as paraffin. Refining could be adjusted, as in the United States, to yield 50 per cent of petrol and 17 per cent fuel oil. Such a change in refinery technique in Britain would result in British petrol requirements being met by half the present import of crude oil. Again, the trend towards oil is largely based on the comparison between modern oil-fired appliances and obsolete hand-fired coal-burning appliances. The advantages of oil-burning are certainly sometimes more apparent than real. What would be the position if a cheap industrial gas made by total gasification from coal were made available ? The advocacy of this development is strongly supported; indeed a call is made for a higher priority in the pursuit of this subject. It is believed, too, that industry would be bound to respond to its solution for manifold reasons. Taking the long view, as regards the future of the coal fields, this could well be an almost universal method for the utilization of coal, for it is the only foreseeable solution at present of the sulphur problem.

BIOCHEMISTRY OF HUMAN TUMOURS

DURING November 17–19, an international conference on the biochemistry of human tumours was held at the University of Wisconsin, Madison. This meeting was sponsored by the Biochemistry Committee of the Cancer Chemotherapy National Service Center, National Cancer Institute, U.S. Public Health Service, with the present writer serving as programme chairman. Those invited to attend included five scientists from Europe and fifty-five from the United States. Among these were pathologists, clinical cancer chemotherapists, biochemists and biologists. The need for this conference arose from the conviction of members of the Biochemistry Committee, expressed in a guest editorial (James F. Holland and Charles Heidelberger, "Human Cancer, the Primary Target", *Cancer Research*, 20, 975–6; 1960), that despite formidable technical difficulties, increased biochemical research must be carried out on human tumours. This should include studies on the enzyme patterns of human tumours as compared with normal tissues, as well as research on the metabolism and mechanism of action of active tumour-inhibitory drugs in the human cancer patient and *in vitro* with specimens obtained at surgery or by biopsy.

The meeting was opened by James F. Holland (Buffalo, U.S.A.), who pointed out some of our major deficiencies in knowledge about human cancer. He directed attention to the variability of human tumours, even of the same kinds, with respect to growth-rates and patterns, and to their response to chemotherapeutic agents. Even though extensive work has been done on biochemical mechanisms of action of various antimetabolites in susceptible and resistant transplanted rodent tumours, similar work on human tumours is almost totally lacking. Moreover, there is little information on enzyme activity in human tumours, and on the effects of tumours on host metabolism, as exemplified by terminal cachexia. Holland felt there is a particular need to develop new methods to measure the growth-rates of inaccessible tumours and to get a measure of the amount of stromal and necrotic contamination of tumour specimens.

A brief review of human tumour pathology was given by Paul Kotin (Los Angeles), who showed a number of slides to illustrate diversity even among similar types of human tumours. He made the point that there is little, if any, correlation between the histological appearance of tumours and the carcinogenic stimuli that produced them. Therefore, he suggested that biochemical patterns reflecting essential consequences of the carcinogenic process might be studied more meaningfully in pre-neoplastic tissues, such as carcinomas *in situ*, rather than in the fully developed and highly diversified tumours. He also suggested that work be carried out to understand the differences in natural history between certain tumours in children and their counterparts in the adult. The morphological considerations were carried to another order of resolution by Francoise Haguenau (Paris), who discussed the electron microscopy of human tumours. She demonstrated with elegant slides the diversity of human tumours with respect to the appearance of the submicroscopic cellular organelles. Furthermore, some cells that appeared similar in the light microscope were found to differ markedly in their ultramicroscopic morphology, and she was able to distinguish on this basis between the α- and β-cells of Caspersson.

A. R. Curreri (Madison) discussed the surgeon's role in the collection of surgical specimens, and emphasized the willingness of surgeons to collaborate in co-operative enterprises provided that the purpose of the research was made clear. Much discussion followed, which was summarized by Holland: "Know thy surgeon and love thy biochemist".

A detailed discussion of the techniques that have been developed for low-temperature storage, with maintenance of viability, of cells grown in tissue culture was given by Cyril Stulberg (Detroit). The application of these methods to the storage of sections of human tumours, which would be essential in any proposed large-scale co-operative studies of tumour enzymology, remains to be worked out.

Because of the extreme heterogeneity of specimens of human tumours, it is clear that micro- and ultramicro-methods are required in most cases in order to obtain meaningful information. Accordingly, David Glick (Minneapolis) and Oliver Lowry (St. Louis) discussed in some detail the elegant and precise techniques that they have developed for the quantitative assay of enzymes extracted from samples the size of common histological sections and by microdissection. These involved mainly colorimetric, spectrophotometric, and fluorimetric methods. Another technique for enzyme assays with very small samples was described by V. R. Potter (Madison), involving the use of labelled substrates of high specific activity, paper chromatography, and the use of automatic recording equipment for the direct determination on the paper strip of the radioactivity in the substrate and product.

His extensive work on the amounts of some twenty enzymes in 800 human tumours by various histological staining methods was described by R. G. J. Willighaghen (Leyden). An enormous diversity of results was found; some enzymes were present in some tumours and absent in others from the same organ and of the same histological type. However, in some cases it has been possible to predict the clinical behaviour of tumours based on histochemical observations. Using similar techniques, L. Wattenberg (Minneapolis) reported that aminopeptidase, an enzyme not found in the normal gastric mucosa, occurs in many gastric malignancies, and in this metabolic feature resembles intestinal metaplasia of the stomach and also the mucosa of the small bowel.

James Danielli (London) pointed out that no single variable has been found in tumours to serve as a basis to design new drugs. Therefore it is necessary to summate small differences in order to obtain responses. He discussed his interesting research on the Walker 256 rat carcinosarcoma with aromatic nitrogen mustards containing a urethan group, which require enzymatic cleavage by the tumour before the mustard becomes active. He was able to demonstrate that feeding a chemotherapeutically inactive phenylurethan derivative to rats raised the level of the cleavage enzyme in the tumour, which resulted in a potentiation in chemotherapeutic effectiveness when the substituted mustard was given afterwards. This approach of inducing an enzyme in tumours that would liberate the active drug from a non-toxic precursor was discussed extensively.

Henry Pitot (Madison) described his work (in collaboration with V. R. Potter) on the enzymatic constitution of a series of transplanted rat hepatomas as compared with that of normal and regenerating liver. A number of marked differences were found, and enzymological evidence was presented to suggest strongly that the Novikoff hepatoma arose from bile-duct cells, whereas the Dunning hepatoma arose from parenchymal liver cells. In the case of the Morris 5123 hepatoma no qualitative difference between the tumour and liver was found in assays of some thirty different enzymes. However, several enzymes in liver that show marked variations in response to substrate administration and dietary changes showed no such response in the 5123 hepatoma under similar conditions. This may indicate that some biochemical control mechanisms may be lacking in this tumour.

A study, by conventional biochemical techniques, of about twelve enzymes and six analytical parameters was reported for twenty-three human tumour specimens by George Boxer (Rahway, New Jersey). He stressed the diversity and heterogeneity of the samples as examined by various criteria and the necessity of standardizing rigorously the enzymatic assays and determining stability under the frozen storage conditions employed in this work. The difficulty of deciding the basis to which the enzyme activity should be referred (wet weight, protein, deoxyribonucleic acid, etc.) was discussed in some detail. He and several others have used an analysis for collagen as an indication of the amount of connective tissue contaminating the tumour samples, but this has not as yet proved satisfactory.

C. de Duve (Louvain) discussed a strategic approach to chemotherapy by classifying the various enzymes that affect or are affected by a given drug. The target enzymes are acted on by the drug: a positive target would be the release or activation of enzymes that might kill cells, such as lysosomes; a negative target would be an enzyme which if inhibited would result in cell death. Auxiliary enzymes were defined as those acting directly on the drug; a positive auxiliary would convert the drug into a more active form; a negative auxiliary would detoxify the drug. It was agreed that this would be a useful way to consider mechanisms of drug action. de Duve also believed that it would be more useful to study a few enzymes very completely in human tumours than to carry out a superficial survey of the amounts of many enzymes.

At this point there followed thirty-two brief presentations by the remainder of the participants in the conference. These ranged from the purely conceptual to the presentation of potentially useful techniques, and stressed work on the mechanism of action of various chemotherapeutic agents in human beings. An open discussion followed.

The meeting was marked by a congenial spirit established among the participating pathologists, surgeons, clinicians, and biochemists that augured well for the future of this type of research, which requires close co-operation and mutual understanding among workers. The pall cast over the conference by the pathologists' demonstration of the tremendous heterogeneity and diversity of human tumours was never completely dispelled, however, and the most urgent problem to be solved before productive work can be done is to develop quantitative methods to cope with this situation, so that meaningful criteria can be established. It was agreed that all work should be done under strict histological control. The majority of the participants felt, with some vigorous dissenters, that this work would have to be carried out on a small scale in order to produce meaningful results. Some expressed the view that overall metabolic studies in cellular systems, particularly when dealing with mechanisms of drug action, might be more useful than enzyme assays, but all agreed that more work with human tumours was needed.

On the day following the conference, a small meeting of some of the participants was held to discuss organization of research in this field. It was agreed that informal study groups would be set up among the participants of the conference to discuss, by correspondence and afterwards by informal meetings, three general areas considered to be of crucial importance at this time. The first will deal with the problem of the diversity and heterogeneity of human tumours and the development of suitable techniques and a basis for meaningful biochemical studies. The second will involve asking biochemists interested in the enzymology of tumours to make recommendations as to which enzymes would yield most fruitful results on investigation. The third will deal with the stimulation of additional research on mechanisms of drug action in human cancer patients and *in vitro* in surgical and biopsy specimens of human tumours. Initially these activities will be co-ordinated and sponsored by the Cancer Chemotherapy National Services Center. Investigators who wish to have additional information or wish to participate in this programme are invited to communicate with Dr. J. Leiter or Dr. S. Schepartz at that agency.

The challenge of research with human tumours is one that is worthy of the interest, ingenuity, and participation by all scientists interested in cancer, working as individuals or as interdisciplinary teams. In order for this challenge to be met adequately a mobilization of scientific talent all over the world is required. The meeting recently held in Madison was a modest step in this direction. It is to be hoped that similar meetings may be held in other regions of the world, encouraged perhaps by some of the participants in this meeting. At some time in the near future, once some of the formidable technical problems have been solved, it may be appropriate for some agency such as Unesco to arrange for the exchange of information in this field at an international level.

CHARLES HEIDELBERGER

HAZARDS OF RADIATION

THE committee on radiological hazards to patients, with Lord Adrian as chairman, has now published its second report*. The first, an interim report dealing only with mass miniature radiography, was issued in 1956 and has been reviewed previously (*Nature*, 178, 453; 1956). The present report is devoted to considerations of the long-term genetic hazard to the population as a whole arising from the average radiation-dose received by the population in excess of that from natural sources. The statistical nature of the investigation and of its results is stressed; although doubling the average dose of 3 r. to the gonads during reproductive life might give reason for concern from a genetical point of view, a gonad-dose of 6 r. received by a single individual is not likely to cause abnormalities in the immediate progeny.

The conclusions of the committee are based on two nation-wide surveys. During one week in May 1957, a survey was made in Britain of the numbers and types of X-ray examinations carried out, of the number of films used, and of the apparatus available in all National Health Service hospitals and chest clinics, in dental surgeries and in a few other institutions. Including fluoroscopic examinations, this survey covered a total of 259,457 radiological examinations. The second survey, during one week in December 1957, was made in a random selection of about one quarter of the National Health Service hospitals and chest clinics, and totalled 55,065 radiological examinations. These surveys were supplemented by physical measurements (totalling about 14,000) of the radiation-dose received by patients undergoing different types of radiological procedures in a representative sample of 130 hospitals and chest clinics.

When account is taken of seasonal differences in the frequency of examinations, the data from both surveys agree in indicating a total of 13·0 million radiological examinations during 1957. This is somewhat more than the corresponding figure of 12·2 million used in the Medical Research Council's first report. In large part this may be due to the much more restricted sample that was available for the earlier estimate. More important, and possibly an indication that the recommendations of 1956 had already influenced radiological practice in 1957, was a difference in age distribution of patients examined in the two reports. While in 1956 it had been estimated that 31·9 per cent of all examinations had been given to the age group 0–14, and 25·9 per cent to the over-fifty age group, the corresponding figures in 1957 were 13·5 and 34·4 per cent. From a genetical point of view, this is a desirable development; for the potential effect of a given dose on future generations is greater in a young person having a high expectancy of parenthood than in an older person. In fact, the calculations of genetical hazards in the present report make use of fertility factors giving the average child expectancy at each age for arriving at the "genetic dose to the population". By this is meant the gonad-dose which, if given to every member of the population, would have the same effect as the sum of the individual doses actually received.

The results of the surveys are expressed as mr. (milliroentgens) annual genetic dose per head of the population. All medical radiology in 1957/58, both diagnostic and therapeutic, resulted in a genetic dose of 19·3 mr. This is less than the figure for diagnostic radiology alone (22 mr.) in the Medical Research Council's report of 1956. The main contributions to the total of 19·3 mr. are: diagnostic radiology 14·1 mr., radiotherapy of non-malignant conditions 4·5 mr., radiotherapy of malignant conditions 0·5 mr.; minor contributions are made by medical uses of radioactive isotopes (0·18 mr.), mass miniature radiography (0·01 mr.) and dental radiography (0·01 mr.). The dose to the gonads from any X-ray examination is small in comparison with that considered by the Medical Research Council to be acceptable to the individual without causing undue concern on behalf of himself or his offspring. The committee therefore concludes that there is no need for major restrictions in radiological practice, and that the number and types of examinations or treatments must be dictated by the clinical needs of the patient. Nevertheless, it considers that, whenever possible, the gonad-dose should be reduced even further, and it gives detailed recommendations how this can be done, especially in the case of pregnant women. It is satisfied that, if these recommendations are followed, the total annual genetic dose to the population from all forms of medical radiology can be reduced to a figure of 6 mr. or less. C. AUERBACH

PHYSIOLOGY OF SUGAR-CANE

R. L. BIELESKI (*Australian J. Biol. Sci.*, 13, 203; 1960) has found that the sugar uptake by sugar-cane storage tissue takes place in two stages. In experiments in which slices of mature and immature storage tissue were used, the initial uptake reached an equilibrium within 1 hr., the level being proportional to the external sugar concentration: it was independent of the sugar, and was unaffected by anaerobic conditions. When the tissue was placed in water, this sugar diffused out rapidly, that is, it was contained in the apparent free space, 10–20 per cent of the tissue volume. The secondary uptake continued up to 60 hr. at a slow, constant rate, 1–5 mgm./gm./day, independent of sugar concentration above 2·0 per cent, dependent on the sugar, and inhibited by anaerobic conditions. This sugar did not diffuse out when the tissue was placed in water. The secondary uptake thus appears to involve an active accumulation process. The sucrose content of the tissue increased during accumulation, which occurred against a 10- to 200-fold concentration gradient. There was no starch synthesis, but accumulation was associated with a 30–40 per cent increase in respiration. Sucrose was not hydrolysed prior to accumulation, and when slices accumulated sugar from a mixed solution, sucrose uptake inhibited glucose uptake. Internodes which were most active in storing sugar in the field gave the most actively accumulating preparations in laboratory experiments. Mature tissue slices showed little or no ability to accumulate sugars.

In further work on the effects of inhibitors on sugar accumulation, the author (*ibid.*, p. 221) has noted that various metabolic inhibitors, at pH 5·5, affect sugar accumulation in immature sugar-cane storage tissues. The rate of accumulation was reduced by 10^{-5} M mercuric ion, 10^{-5} M p-chloromercuribenzoate, cyanide, and cupric ion, and 2×10^{-3} M phloridzin. Accumulation was completely inhibited and sugar leakage induced by 10^{-5} M dinitrophenol, 10^{-4} M mercuric ion, and 10^{-3} M p-chloromercuribenzoate, cyanide, cupric ion, azide, arsenate, and iodoacetate. The effects of 10^{-5} M dinitrophenol and 10^{-4} M cyanide were reversible, but that of 10^{-3} M cyanide was irreversible. Only slight effects were produced by borate, phosphate and magnesium ions. The behaviour of sugar-cane sugar accumulation towards inhibitors is apparently similar to that of other transport mechanisms, being somewhat more sensitive than most plant processes and less so than animal ones. It differed from sugar accumulation in animal tissues in showing no specific sensitivity to phloridzin. The results suggest that sugars are contained within the immature storage cell by the continuous operation of a metabolic storage mechanism rather than by an impenetrable barrier to sugar diffusion.

VIRUSES AND PLANT DISEASES

THE investigations of Dr. L. O. Kunkel into the relationships between viruses and plant diseases are described in the *Rockefeller Institute Quarterly* (4, No. 2; Summer, 1960).

Kunkel discovered that the aster yellows disease is carried by a leafhopper and is caused by one of the few viruses that is equally at home in hosts of the plant and animal worlds. First, he observed that during the hot summer months the aster yellows disease diminishes in plants, and showed that the causative virus is sensitive to heat. Dr. Kunkel was able to cure infected plants of several virus diseases by growing them at temperatures which destroyed the virus without destroying the plants. Peach yellows is one of the diseases which responded to heat treatment. The heat-treatment technique also enabled Dr. Kunkel to deduce that the aster yellows virus multiplies in its leafhopper carrier as well as in the plant it infects. To do this, he subjected the insects to heat and noted how they regained their infectivity. He concluded that the virus must multiply in the insects, reaching a level of maximum infectivity in about two weeks. Direct evidence for this was found by L. M. Black, using a technique developed in Africa by the English scientist, H. H. Storey, to inoculate minute leafhoppers with measured amounts of virus.

Secondly, in his work on the transmission of yellows viruses, Dr. Kunkel discovered two related strains of aster yellows virus, each of which will protect plants against infection by the other, a phenomenon known as cross-protection. He also found cross-protection between viruses in the leafhoppers as well. Dr. Karl Maramorosch, who began work at the Institute with Dr. Kunkel, has continued his studies of plant viruses. He confirmed the complex relationships existing between two strains of the corn stunt virus and the leafhopper that transmits them from plant to plant. Of the two strains of the virus, plants infected by one are protected against infection by the other, but the second will not protect a plant against the first. Similarly, infection of a leafhopper by the first will prevent it from becoming infected afterwards with and transmitting the second. In the insect also, the second virus strain will not protect against the first. These findings regarding corn stunt virus confirmed Kunkel's discovery that two related strains of aster yellows virus would protect leafhoppers against each other, but Dr. Maramorosch was the first to find unilateral protection.

Maramorosch has also found that a leafhopper which normally feeds on corn can live on aster plants only if the asters are infected with the aster yellows virus. After they feed on diseased asters, the corn leafhoppers are then able to survive on uninfected aster plants. They are then also able to survive on healthy carrot plants, which they could not do before their diet of diseased aster plants. It would appear that the virus infection may actually benefit the insect by widening its potential food plants. The explanation of these phenomena is not yet clear, but Dr. Maramorosch is pursuing his investigations.

DISTILLATION OF ALKALI ELEMENTS DURING FORMATION OF AUSTRALITE FLANGES

By DR. S. R. TAYLOR*

Department of Geochemistry, University of Cape Town

THE flanged australites (Figs. 1 and 2) are the most distinctive members of this well-preserved group of tektites. The common australite forms are distinguished by Fenner[1] as round (buttons and lenses), oval (ovals, boats and canoes), dumbbells and teardrops. 'Cores' may be round, oval or dumbbell shapes. The flanges, which occur most commonly on the round forms, but occasionally on the other types as well, display the often quoted evidence for two periods of melting of tektites. Sections

---

* Now at Department of Geophysics, Australian National University, Canberra.

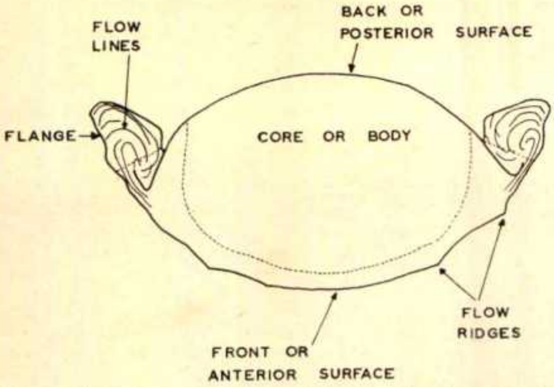

Fig. 1. Typical flanged australite (after Baker[4]). The dashed lines indicate portions analysed

indicate that the material forming the flanges has melted at the anterior surface (Fig. 1) and has flowed back to form the flange around the unmelted core. The flow-lines are clearly shown in the figure by Fenner[2] and in the striking photographs by Fenner[3] and Baker[4,5]. This evidence, together with such features as 'flow ridges' seen on the anterior surfaces, has been interpreted by most workers, as being due to high-speed ('ultra-supersonic') flight through the atmosphere, or to the passage of a blast of hot gas over the tektites. Fenner[3] and Baker[5] have been able to relate the common forms of australites to such a sculpturing process.

The evidence for an origin of the flanges during a second period of melting, although strong, is not universally accepted. Thus Hawkins[6], in discussing a proposed origin of tektites through fusion of sandy clays by lightning, states that: "It is perhaps possible for the buttons with flanges, dumbbells and other shapes to be formed by fusion within the ground. It is not correct to assume that these shapes can only be produced by the melting of a tektite during supersonic passage through the air".

Forms bearing a general resemblance to flanged australites have been made by firing lead bullets against a metal target. Baker[5] shows photographs of these, with well-developed flanges, and a central core.

Very little is known about the relative composition of flanges and cores. Baker[5] has directed attention to the difference in specific gravity between flanges, which average 2·385 and body portions, with an average of 2·426, which suggests a higher silica content for the flanges. Baker and Gaskin[7] give separate analyses labelled australite glass (flange) and australite glass (core). The analyses do not show significant differences, except that calcium oxide is lower in the core. No figures are given for sodium monoxide and potassium monoxide, which are listed as "n.d.".

If the flanges are due to heating and remelting due to passage through the atmosphere, then some selective loss of the more volatile components may be expected. From experience with the behaviour of elements during arcing of silicate powders in spectrographic analysis[8] as well as from data for the boiling points of oxides, losses of such 'volatile' elements as arsenic, mercury, cadmium, bismuth, thallium, indium, silver, zinc, tin, lead, copper, calcium, lithium, sodium, potassium, rubidium and cæsium might be anticipated. Loss of sodium and potassium, which are major constituents, the abundance and distribution of which in australites is reasonably well known, would be simplest to interpret. It is the purpose of this article to show that, in comparison with the core or body, the flanges contain significantly lower amounts of these two elements, and that there are strong indications that lithium, rubidium and cæsium also follow this pattern.

Two imperfect specimens of flanged australites were available as well as a separate piece of flange. These are shown in Fig. 2. The number of specimens, though small, is sufficient to establish whether a significant difference exists between the composition of the core and the flange, and involves a minimum destruction of these interesting objects.

The entire samples were first cleaned by boiling in 5 *N* hydrochloric acid (analytical reagent) and washed in alkali-free distilled water. The projecting portions of the flanges were removed using a small chisel. The remaining portions of the flanges, as well as the anterior surface of the australites, were removed by grinding, leaving the central part of the core for analysis. The portions selected for analysis are shown in Fig. 1. The cleaning treatment was repeated, on the separated cores and flanges, before crushing in a steel mortar to pass 20-mesh nylon cloth, in a plastic sieve holder. A hand magnet was used to extract metal before grinding in an agate mortar to pass 120 mesh.

Sodium and potassium were determined using an EEL flame photometer, under conditions identical with those fully described by Taylor[9]. Natural silicate standards such as the standard granite

Table 1. Analytical Data for Cores and Flanges of Australites

Locality	Sample No.		per cent sodium	per cent potassium	p.p.m. lithium	p.p.m. rubidium	p.p.m. cæsium
Charlotte Waters, Central Australia (625)	*A*	core	0·894 ±0·002	1·860 ±0·004	47·4 ±1·8	89·9 ±3·2	2·91 ±0·30
		flange	0·694 ±0·001	1·705 ±0·002	42·4 ±0·8	77·9 ±1·4	2·64 ±0·36
		per cent difference	22·5	8·3	10·5	13·3	9·3
Mount Elephant, Victoria (1)	*B*	core	0·813 ±0·004	1·732 ±0·007	37·3 ±2·5	72·8 ±3·7	1·61 ±0·10
		flange	0·698 ±0·003	1·633 ±0·003	35·7 ±0·8	68·8 ±3·1	1·44 ±0·19
		per cent difference	14·1	5·7	4·3	5·5	10·6
Mount Elephant, Victoria (10)	C	flange	0·635 ±0	1·621 ±0·001	34·5	67·6 ±1·3	1·83 ±0·21
Average of three flanges			0·68	1·65	38	71	2·0
Average values for 24 australites (ref. 9)			0·90	1·85	42	81	2·5
Overall analytical precision (*C*) (per cent)			2·5	2·5	5·8	7·6	14·8

(*G*-1), diabase (*W*-1)[10] U.S. Bureau of Standards soda feldspar (99), plastic clay (98) and the MIT standard biotite (B-3203) have been used and it is believed that systematic error is small.

Lithium, rubidium and cæsium were determined by emission spectrography under conditions similar to those reported by Taylor[9], for the determination of cæsium. Kodak I*L* plates were used in place of I*N*, used previously, and *Li* 8126 was used in place of *Li* 6103. Results are given in Table 1.

It can be seen that for the two samples where data are available for both core and flange, that the flange contains less of the alkali elements than the core. The percentage difference in composition is very much greater than the precision of the individual determinations for sodium and potassium, and these elements must be considered to be significantly lower in the flanges, compared with the cores. For lithium the flange of sample *A* is 10·5 per cent lower than the core; for sample *B*, the difference is 4·0 per cent. Rubidium is 13·3 and 5·8 per cent lower, respectively, in these samples. The difference between core and flange is clear for these elements in sample *A*, and about equal to the precision for sample *B*. The analytical precision for cæsium is much less satisfactory, due principally to the necessity for corrections for background, with a high background to line ratio. The difference in cæsium content between cores and flanges is less than the difference between replicate determinations. The overall precision of the analytical methods expressed as relative deviation, *C*, and based on many determinations, is given in Table 1 as well. It can be seen that the difference between core and flange is less than one relative deviation for lithium in sample *B*, and only about one-half the relative deviation for cæsium in both samples *A* and *B*. In summary, the difference in composition is clear for sample *A* (except for cæsium) and for sodium and potassium in sample *B*, but less clear for the rarer alkali elements in that sample. It is believed that greater precision in the spectrographic determinations would confirm the present indications of loss of these trace elements.

Sample *C* consists of a flange only (the small portion of core which was removed prior to analysis, was insufficient for the determination of sodium and potassium). Only one published australite analysis[11,12] has less potassium (1·04 per cent). No published analysis reports a lower amount of sodium, the minimum figure being 0·68 per cent sodium[12]. For comparison, the averages of the alkali elements in 24 australites[9] are shown. This total includes the two cores given in the same table, but no flanges, and it can be seen that the figures given for the three flanges are substantially lower than these averages.

Fenner[3] and Baker[4,5] discuss the origin of australite flanges by ablation during high-speed flight through the atmosphere, and Baker[5] gives a graphic illustration of this lively process. The loss of the more volatile elements during flange formation indicates that a process such as that envisaged by Baker and Fenner, in fact, occurred. No hypothesis of flange formation by flattening on impact, or by formation at the same time as the initial melting as required by Baldwin, will explain the difference in chemical composition. It is decisive evidence that the flanges are secondary features, due to a second period of melting, during which selective distillation of the alkali elements occurred.

Several points of interest remain for investigation. High-speed flight of tektites through the atmosphere will result if they were formed during the comet explosion, as envisaged by Urey[13], so that the evidence presented here does not rule out a terrestrial origin. The velocity of flight through the atmosphere could be a critical factor. If tektites are of extra-terrestrial origin, they must have entered the atmosphere at velocities in excess of 11·2 km. sec.$^{-1}$. The rather delicate sculpturing of australites, as well as the selective loss of the alkali elements from the flanges, indicate less-severe conditions than those experienced by meteorites. Comparison with the selective distillation of the alkali elements from powdered tektites in a d.c. arc, at temperatures of 3,000–4,000° K. (ref. 8), indicates temperatures of a few thousands, rather than tens or hundreds of thousands of degrees, for the second period of melting of tektites. It is to be hoped that this aspect will be studied by physicists interested in re-entry problems.

In conclusion, it should be noted that the average composition in major elements of tektites may be matched by that of a 3 : 1 mixture of the non-volatile constituents of shale, and quartz[14,15]. The trace element content of australites[16] supports the composition suggested above. It is possible that there is a general deficiency of the more volatile trace elements in tektites, compared with this parent material. Copper[16], gallium[17] and possibly lead seem to be lower (by factors of one-half) than would be expected in such a quartz-shale mixture. Such losses would result from the initial melting process.

The evidence from their chemical composition is strongly in favour of a terrestrial origin for tektites. The external sculpture of australites, and selective loss of alkali elements during flange formation, point unequivocally to a second period of melting. The current enigma presented by the tektites is how to reconcile a terrestrial composition, an initial melting of short duration, and a second period of melting rationally explained by high-speed flight through the atmosphere. Only the comet theory proposed by Urey[13] approaches an adequate explanation.

I am indebted to Miss Maureen Sachs for the analytical determinations. The Director, South Australian Museum, Adelaide, provided sample *A*, and the Director, National Museum of Victoria, Melbourne, sent samples *B* and *C*. Without their generous co-operation, this investigation would not have been possible.

PALÆOMAGNETISM IN SOME EAST GREENLAND SEDIMENTARY ROCKS

By D. E. T. BIDGOOD and W. B. HARLAND

Department of Geology, Sedgwick Museum, University of Cambridge

DURING a visit to Central East Greenland in 1957, on the invitation of Dr. Lauge Koch[1], we collected specimens of sedimentary rocks, with the view of examining their magnetism. This article summarizes the results from the late Pre-Cambrian (two horizons), from the Permian, and from the Middle and Upper Trias. Other rocks collected (igneous rocks, lowest late-Pre-Cambrian horizon, Devonian, Lower Carboniferous, etc.) require further investigation, some being unstable. All the results, with a full discussion, will be published in *Meddelelser om Grønland*, with stratigraphical details and references.

Specimens were oriented in the field by rock compass[2]. In the laboratory the rocks were re-oriented, cored and measured on the astatic magnetometer housed at the Department of Geodesy and Geophysics, Cambridge. For these facilities we are indebted to Mr. B. C. Browne and Dr. J. C. Belshé. Afterwards, a second magnetometer was constructed for this work in the Sedgwick Museum, Cambridge. From each rock one or more samples were measured, and when necessary the vectors combined by taking means of the direction cosines to give a single mean vector for each rock, this mean vector forming the basic unit. After correcting for the effects of dip, the mean vectors from all the rocks of a similar age were combined by taking the mean of the direction cosines, and a statistical estimate of the dispersion was made by Fisher's method. These group mean positions were then used to give the position of the magnetic pole[3]. The main computations were carried out on the Cambridge digital computor *Edsac*.

Table 1

Group	No. of rocks	Dip corrected: *D*	*I*	*α*	*κ*	Position of pole Lat.	Long.	dχ	dψ
Middle and Upper Trias	44	358	68	3	41	160E	68N	5	4
Permian	10	175	−37	7	50	163E	38N	8	5
Tillite Formation	16	135	16	18	5	161W	04N	19	10
Multicoloured Series	10	110	36	9	31	141W	13S	10	5

Explanation of columns:
D, declination in degrees measured from true north.
I, inclination to the horizontal in degrees, positive downwards, negative upwards.
α, semi-angle of the cone of confidence drawn at 95 per cent probability-level.
κ, estimate of precision.
dχ, dψ, semi-axes of the ovals of confidence drawn at the 95 per cent probability-level.

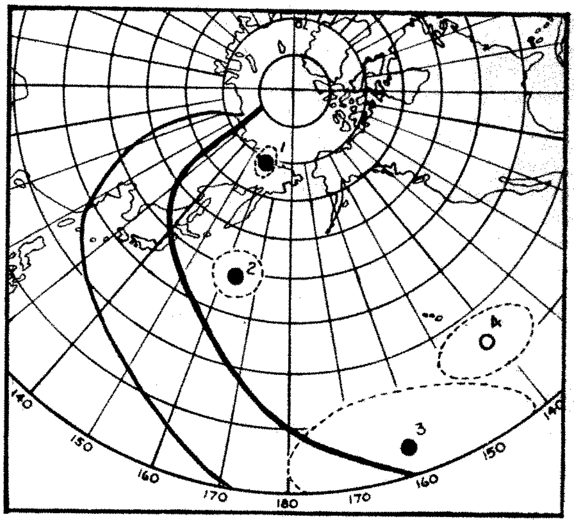

Fig. 1. Polar projection showing positions of magnetic poles derived from (1) Middle and Upper Trias; (2) Permian; (3) Tillite Formation; (4) Multicoloured series. ●, pole plotting in northern hemisphere; ○, pole plotting in southern hemisphere; broken lines show ovals of confidence drawn at the 95 per cent level. For comparison, the approximate path of north pole inferred from British rocks (thick line) and the path inferred from American rocks (thin line) are shown, after Creer *et al.* (ref. 5)

Table 1 lists the group mean positions and pole positions; the latter are shown graphically in Fig. 1.

(1) The Middle and Upper Trias rocks were sampled at Kapp Biot, where 44 specimens of flat-lying red sandstones and marlstones were collected. These were found to be strongly and uniformly magnetized, with eight of the rocks forming a reversed group directed upwards and to the south, whereas the remainder formed a normal group downwards and to the north. The two groups have been combined to give the group mean position.

(2) Ten flat-lying red sandstones of Permian age collected from the two well-separated areas of Gauss Halvö and Mesters Vig were strongly and uniformly magnetized to the south and upwards, forming a reversed group at a shallower angle than the Middle and Upper Trias.

(3) The tillite formation of uppermost Pre-Cambrian age was sampled on both limbs of an anticline on Ella Ø; many of the fifty-four rocks collected proved too weakly magnetized to be measured, or had vectors close to the present field. Sixteen of these rocks have been combined to give the group mean, on the grounds that they show positive evidence of stability of magnetization by the presence of reversals, low scattering of vector positions between rocks from the same collecting station, and by the use of the tectonic check provided by the anticline. The rocks are of varied lithology, ranging from red sandstones and tillites to grey and brown shales.

(4) The multicoloured series (3,500 m. below basal Cambrian) form part of the Eleonore Bay Formation, which is a thick conformable sequence passing upwards through the tillite formation into rocks of Cambrian age. Ten specimens of red mudstone were collected from two outcrops on the south side of Ruth Ø, where the beds dip gently south-east. The vectors fall into a single well-defined group directed downward to the east.

The polar stereographic projection (Fig. 1) shows the positions of the pole computed from the four sets of vectors. These pole positions fall into the same general area of the Pacific Ocean and Asia as the pole positions obtained by other workers for rocks collected in North America and Europe, and the pole positions of the older rocks show the same tendency to approach the equator, apparently crossing it at a time between the tillite formation and the Upper Eleonore Bay Formation. This is in agreement with results for rocks of similar age from Europe[3], and we[4] have already discussed the implications of this equatorial position coinciding with a major glaciation. The pole positions for these Greenland rocks lie generally about 18° east of the general European trend, or about 30° east of the North American trend, which would be consistent with a post-Trias movement of Greenland away from North America.

Taking into account this postulated movement between the continents and the similar movement that has been suggested between Europe and North America[5], the pole positions derived from rocks of similar age from the three areas can be compared. In the post-Cambrian rocks there is some agreement, and if the comparison is extended into the Pre-Cambrian, the pole position derived from the Greenland Upper Eleonore Bay rocks lies intermediate between the pole positions from the Cambrian and Upper Torridonian of Europe, and between the Cambrian and the late Pre-Cambrian positions from the Upper Keweenawan and Beltian of North America, which accords with the stratigraphic relationship of the Upper Eleonore Bay Series to the overlying Cambrian rocks.

We wish to correct an error in quoting E. Irving's work. The second sentence in our recent communication[4] should read "Palæomagnetic studies in Australia suggest that Permian Tillites were near the . . . pole".

USE OF RADIOACTIVE NITROGEN IN STUDYING NITROGEN FIXATION IN BACTERIAL CELLS AND THEIR EXTRACTS

By DR. D. J. D. NICHOLAS*

Chemical Microbiology Department, Long Ashton Research Station, University of Bristol

AND

DR. D. J. SILVESTER and DR. J. F. FOWLER

Medical Research Council Radiotherapeutic Research Unit, Hammersmith Hospital, London, W.12

THE stable isotope of nitrogen (nitrogen-15) has been successfully employed to follow nitrogen fixation in soil bacteria, blue-green algae and in root nodules of legumes and non-legumes[1,2]. It has also been used recently to demonstrate the incorporation of nitrogen into cell-free extracts of *Clostridium pasteurianum*[3], *Azotobacter vinelandii*[4,5], blue-green algae[6] and those of *Chromatium*[7]. Since the nitrogen-15 technique is time-consuming, some two days being required to complete an experiment from the initial exposure to the gas to the final analysis in a mass spectrometer, we have explored the possibility of using radioactive nitrogen (nitrogen-13, β^+ 1·24 MeV.; half-life 10·05 min.) to study nitrogen fixation in bacterial cells and cell-free extracts prepared from them. We present here details of the technique used together with some of the preliminary results.

Nitrogen-13 has been used previously in chemical[8,9] and biological studies[10]. Carangal and Varner[11], after bombarding thin graphite targets with protons or deuterons in a cyclotron, digested them in acid mixtures and prepared labelled nitrate, nitrite and ammonium compounds which were then supplied to excised plant tissues. Although these workers produced molecular nitrogen-13 by oxidizing labelled ammonia with sodium hypobromite, they did not report its use in biological nitrogen fixation.

In our experiments, nitrogen-13 was produced continuously in the Medical Reseach Council's cyclotron by bombarding coarsely granulated charcoal, retained behind a stainless steel mesh, with

* Member of the Scientific Staff of the Agricultural Research Council seconded to the University of Bristol.

15-MeV. deuterons. The nitrogen-13 was swept from the target in a stream of pure argon through small-bore nylon tubing to the adjacent experimental laboratory, where it was passed through combustion tubes packed with copper at 750° C. and then through Dreschel vessels containing dilute sulphuric acid and alkaline sulphite to remove the last traces of ammonia and any oxides of nitrogen which might be present. The activity of the gas was continuously monitored and its half-life checked at intervals to confirm its identity. With a deuteron beam current of 40 μamp. and an argon flow-rate of 0·5 litre/min., a nitrogen-13 activity of between 30 and 60 mc./litre was produced, contaminated with about 1 per cent of 1·8 hr. argon-41. For experiments with *Azotobacter vinelandii* (*O* strain) the gas was mixed, with the aid of rotameters, with 10 per cent oxygen, which is essential for nitrogen fixation in this organism.

The biological samples contained in 50-ml. Erlenmeyer flasks were exposed to nitrogen-13 by bleeding off a portion of the gas from the main line. The flasks, suspended from a shaker arm in a water-bath at 30° C., had tightly fitting rubber bungs with inlet and outlet glass tubes for the gas. The inlet tube was drawn out to a fine jet which was just clear of the sample (usually 2 ml.) contained in each flask. Eight flasks were connected in series with sufficient polyvinyl chloride tubing to allow for a thorough reciprocating action (80 oscillations per min.) to effect a good exchange between gas and sample. The rate of flow of the gas into this line of flasks was controlled by a pinch-clip, and could be estimated by observing the rate of bubbling as the gas passed through a Dreschel bottle, containing water, at the end of the line. From this point, the gas rejoined the main line, and was swept into a large polythene container on the roof of the cyclotron building where it was allowed to decay before being discharged into the atmosphere.

Azotobacter vinelandii (*O* strain) was grown for 12 hr. in well-aerated nitrogen-free medium in 3-litre flasks[12]. Cell-free extracts of *Azotobacter* were prepared by disrupting about 0·2 gm. fresh weight harvested cells in 30-ml. aliquots of the culture medium (centrifuged at 144,000*g* to remove whole cells) with an ultrasonic titanium probe (M.S.E. Mullard 20 kc./sec.) for 15 min. as described elsewhere[4,5]. The extracts were then centrifuged for 1 hr. either at 25,000*g* or at 144,000*g* in an ultracentrifuge.

Suitable aliquot parts of the supernatant solutions (containing about 0·2 mgm. nitrogen) left after centrifuging, were put in the Erlenmeyer flasks alternating with boiled control samples and the gas mixtures containing nitrogen-13 were flushed through at a rate of about 0·1 litre/min. The samples were well agitated in the water-bath during this period. After exposure of whole cells or their extracts to the tracer, ordinary nitrogen gas was flushed through for 5–10 min. to remove the dissolved active nitrogen gas from the solutions. The samples were then transferred into plastic counting tubes and assayed in a well-type scintillation counter. Each sample was counted for 30 sec. and the observed counting-rates were corrected for the dead-time of the counter where appropriate, and for decay from a suitable standard time, usually taken as 10–15 min. after the end of the exposure.

Table 1. EFFECT OF COMPOSITION OF GAS ON THE UPTAKE OF NITROGEN-13 BY CELLS OF *Azotobacter vinelandii* (*O* STRAIN)
(Counts per sec. referred to a standard time)

Gas mixtures as percentages		Normal cells	Cells boiled for 15 min. before exposure to tracer	Cells treated with 10^{-3} *M* KCN
Argon containing carrier-free nitrogen-13	Oxygen			
80	20	430	60	44
90	10	450	50	42
95	5	350	52	50
98	2	70	48	46

Activity of gas mixtures, approx. 30 mc./litre; gas flow-rate, approx. 0·1 litre/min.; exposure time to radioactive gas mixtures, 10 min.

Cells flushed with ordinary nitrogen gas for 10 min. after exposure to the tracer. 2 ml. cell suspension containing 0·6 mgm. nitrogen were exposed to the tracer for 10 min. and then either flushed with ordinary nitrogen gas for another 10 min. to remove the dissolved nitrogen-13 or else centrifuged at 3,000*g* and the sedimented cells well washed with 0·05 *M* PO_4^{3-} buffer (*p*H 7·5) before assay.

Table 2. EFFECT OF TIME OF EXPOSURE TO TRACER ON THE UPTAKE OF NITROGEN-13 BY CELLS OF *Azotobacter vinelandii* (*O* STRAIN)
(Counts per sec. referred to standard time)

Time of exposure to the tracer (min.)	Normal cells	Cells boiled for 15 min. before exposure to tracer	Cells treated with 10^{-3} *M* KCN
5	280	40	60
10	540	20	40
20	580	41	40
30	500	64	50

Activity of gas mixture (90 per cent argon–nitrogen-13 and 10 per cent oxygen), approx. 30 mc./litre; gas flow-rate, approx. 0·1 litre/min.

2 ml. of cell suspension containing 0·5 mgm. nitrogen were exposed to the tracer and then flushed with ordinary nitrogen gas for 10 min. to remove the dissolved gas.

The results in Tables 1 and 2 show the effect of gas composition and exposure time respectively on the uptake of nitrogen-13 by whole cells of *Azotobacter*. When the gas mixture contained only 2 per cent oxygen there was a marked falling off in nitrogen-uptake. The optimum incorporation of the tracer was achieved with 10 per cent oxygen, and this mixture was used in further experiments. A substantial uptake of nitrogen by cells was achieved by exposing the cell-suspensions to the gas for 10 min. and this was not increased appreciably by longer exposure times. Similar results were obtained when cell-free extracts were used instead of whole cells.

Since early experiments established that the solubility of the gas was sufficient to result in a substantial radioactive count in the boiled samples, methods were devised to eliminate the dissolved nitrogen. For whole cells, two methods proved effective. In the first procedure cells centrifuged at 3,000 *g* for 10 min. were washed with 0·05 *M* phosphate (*p*H 7·5) and then suspended in the buffer and radioassayed as described previously. In the second method, which also proved effective for cell-free extracts, a suitable gas—nitrogen, oxygen or carbon dioxide—was flushed through the system for 10 min. after the extracts had been exposed to the tracer. Results given in Table 3 show that the degassing procedure was quite effective in removing dissolved nitrogen-13 from cell-free extracts. Later experiments confirmed that passing nitrogen gas through for 5 min. was sufficient to remove all the dissolved nitrogen-13 gas from the extracts.

The incorporation of nitrogen-13 into cell-free extracts prepared by centrifuging disrupted cells for 1 hr. at 25,000*g* or 144,000*g* was similar as shown in Table 3. It is of interest that the hydrogenase activity, determined by hydrogen uptake in a Warburg apparatus with methylene-blue as the acceptor[12], was not detected in particle-free extracts after centrifuging at 144,000*g*. During storage at 4° C.

Table 3. UPTAKE OF NITROGEN-13 BY CELL-FREE EXTRACTS OF *Azotobacter vinelandii* (O STRAIN)
(Counts per sec. referred to a standard time)

Experiment	Normal extracts	Extracts boiled for 15 min. before exposure to nitrogen-13
1. Supernatant solution prepared by centrifuging at 25,000*g*	348	110
2. Supernatant solution prepared by centrifuging at 144,000*g*	311	120
3. Solution as in Exp. 2, flushed with oxygen for 10 min. after exposure to the tracer for 10 min.	400	20
4. Solution as in Exp. 2, flushed with carbon dioxide for 10 min. after exposure to the tracer for 10 min.	250	10
5. Solution as in Exp. 2, flushed with nitrogen for 10 min. after exposure to the tracer for 10 min.	200	10

Activity of gas mixture (90 per cent argon–nitrogen-13 and 10 per cent oxygen), approx. 20 mc./litre; gas flow-rate, approx. 0·1 litre/min. exposure time to radioactive gas mixture, 10 min.

Extracts containing approximately 0·15 mgm. nitrogen were flushed for 10 min. after exposure to the tracer, with either oxygen, carbon dioxide or nitrogen. There is no significant difference between the flushing efficiencies shown by Exps. 3, 4 and 5 compared with no-flushing in Exps. 1 and 2.

the particle-free extracts lost their capacity to fix nitrogen more readily than did those centrifuged at the lower speed. Cell-particles appear to be necessary for sustained incorporation of nitrogen-13. Labelled compounds can be detected in the *Azotobacter* extracts and some of them can be removed from the reaction mixtures into various traps. Work is now in progress to determine whether these compounds are intermediates in the fixation process or whether they are formed during side reactions.

Cultures of *Azotobacter vinelandii* (*O*) were kindly supplied by Dr. P. W. Wilson and Dr. R. H. Burris, Wisconsin University, Madison, U.S.A. Mr. G. R. Newbury, formerly with the Medical Research Council Radiotherapeutic Research Unit, first prepared nitrogen-13 by the technique described here. We acknowledge with thanks the valuable assistance of Mr. D. D. Vonberg and the cyclotron team, and the interest and encouragement of Dr. C. A. P. Wood, director of the Medical Research Council Radiotherapeutic Research Unit, and of Prof. H. G. H. Kearns, director of the University of Bristol Research Station, Long Ashton. We also thank Messrs. David Fisher, M. A. Wright, C. A. Fewson and M. A. Proctor, who assisted with certain aspects of the biochemical work, and Messrs. Buckingham and Forse, who assisted with the gas-processing apparatus.

GROWTH OF BACTERIA LABELLED WITH HEAVY ISOTOPES FOR THE ISOLATION OF NUCLEIC ACIDS

By DR. JULIUS MARMUR* and CARL L. SCHILDKRAUT†

Department of Chemistry, Harvard University, Cambridge, Massachusetts

IN studying the interactions of nucleic acids, as well as their genetic fate and function using the technique of cæsium chloride density gradient centrifugation[1], it is desirable to prepare deoxyribonucleic acid (DNA) as well as ribonucleic acid (RNA) of high density by homogeneous labelling. Both ^{15}N and $^{13}C^{15}N$ have been used successfully for this purpose[2,3]. Unfortunately, the substitution of 5-bromouracil for the thymine in the DNA of bacteriophages, bacteria and tissue culture often results in an inhomogenous distribution of label in the DNA, causing it to form bands over a broad range of density[4].

Conditions have been ascertained that will allow organisms with simple growth requirements to grow on 99+ per cent heavy water (D_2O) containing $^{15}NH_4Cl$ as the sole source of nitrogen. More fastidious organisms (for example, *Diplococcus pneumoniae*) can be grown on a complex medium generally used for the organism, replacing the water with heavy water.

The D_2O-^{15}N medium employed is a modification of that used by G. S. Stent (personal communication) and consists of the following:

Table 1

KCl, 150 mgm.
$^{15}NH_4Cl$*, 25 mgm.
NaCl, 500 mgm
K_2HPO_4, 100 mgm.
Na_2SO_4, 5 mgm.
$MgCl_2.6H_2O$, 10 mgm.
$CaCl_2$, 0·2 mgm.
$FeCl_3.6H_2O$, 0·2 mgm.
Glycerol, 0·15 ml.
60 per cent sodium lactate, 0·02 ml.
D_2O† to make 100 ml.

* Obtained as 99 per cent excess nitrogen-15 from Isomet Corporation, Palisades Park, N.J.

† D_2O of 99·7 per cent purity was obtained from Liquid Carbonic Co., California.

Phenol red indicator is added, the *p*H is adjusted to 7 with NaOD, and the solution is sterilized by filtration. The addition of a small amount (20 μgm./ml.) of casein hydrolysate stimulates growth in heavy water if $^{15}NH_4Cl$ is to be omitted.

Since the bacteria seem to take up water preferentially in the initial stages of growth, resulting in a bimodal distribution of DNA density, the following steps have been taken to avoid traces of water in the 99 per cent D_2O medium. The mixture (omitting the trace elements) is first dissolved in 10–25 ml. of heavy water and evaporated to 1 ml. Then heavy water and trace elements are finally added to make 100 ml. Stock solutions should be prepared using heavy water as the solvent. Solutions should not be autoclaved, because the medium will exchange with ordinary water to the extent of several per cent.

---

* Present address: Graduate Department of Biochemistry, Brandeis University, Waltham, Massachusetts.

† Predoctoral Fellow of the National Science Foundation.

Most organisms will grow very slowly, and some not at all, if suddenly exposed to high concentrations of heavy water. To overcome this difficulty, growth is initiated by inoculating about 10^5 cells into a small aliquot (about 1 ml.) of the heavy water medium to which a small quantity of sterile physiological saline (in ordinary water) has been added, so that the concentration of D_2O is about 60–70 per cent. The cells are exposed to the normal conditions of temperature and aeration and when the cell titre reaches about 10^8 per ml., fresh aliquots of the 99 per cent heavy water medium are added periodically to replenish nutrients and neutralize the culture medium. Neutralization in the latter stages of growth is best accomplished by adding (with concomitant swirling) the same medium adjusted to *p*H 10 or 11. In some cases (for example, *Bacillus subtilis*) this gradual adjustment of *p*H is preferred, since, if the alkalinity accidentally reaches too high a level, cell lysis will occur. Once the cells have been adapted to growing in 99+ per cent heavy water, they may be used in subsequent harvests by inoculating directly into fully deuterated medium. Since the adaption of micro-organisms to heavy water is slow[5], cultures should be checked periodically for contamination.

The D_2O-^{15}N medium has been employed successfully for the growth of *Alcaligenes faecalis, Salmonella typhimurium, Pseudomonas aeruginosa, Aerobacter aerogenes, Klebsiella pneumoniae, B. cereus, B. subtilis, Escherichia coli* and *Serratia marcescens. D. pneumoniae* was grown in a complex growth medium containing 99 per cent heavy water. Viable titres of 5×10^8 bacteria/ml. have been attained with most of these bacteria. DNA was isolated from the cells by the method of Marmur (unpublished work) in the presence of ordinary water containing reagents. The deuterated nitrogen-15 containing DNA is of high molecular weight (about 10×10^6 as estimated from the band-width in the cæsium chloride gradient). In the case of *Serratia marcescens* DNA, it was found that the mid-point of the rise in absorbancy at 260 mμ as a function of temperature was the same for the labelled and unlabelled samples in ordinary physiological saline, indicating that strand separation takes place at the same temperature for both. DNA isolated from wild-type *B. subtilis* grown in this medium exhibited the same activity in biological transformation as similar non-labelled DNA. The buoyant densities in cæsium chloride of the DNA samples isolated thus far are listed in Table 2.

It should be noted that the heavy DNA obtained showed a typically narrow distribution of bands in a cæsium chloride density gradient when examined in the analytical ultracentrifuge. The variances of the heavy labelled and normal DNA bands agreed within 20 per cent. This seems to be a considerable improvement over the 5-bromodeoxyuridine labelling technique, which usually results in heavy-labelled material producing a band skewed in the direction of light density. In addition, with the deuteration technique, no visible amount of the non-labelled DNA or bands of intermediate density are found. Fractionation by cæsium chloride preparative density gradient, which has been reported in the work with 5-bromouracil containing DNA, is therefore unnecessary with deuterated DNA preparations.

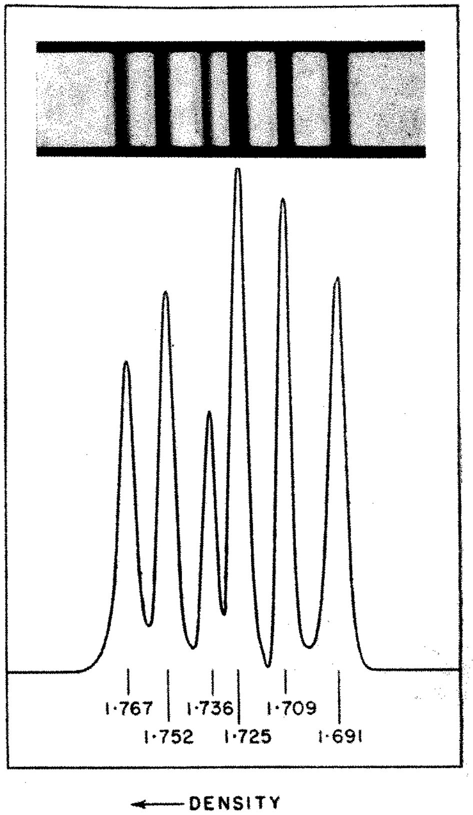

Fig. 1. Ultra-violet absorption photograph and microdensitometer tracing of normal and various labelled samples of DNA isolated from *E. coli* B. Bands have been made in a cæsium chloride density gradient formed by centrifugation at 44,770 r.p.m. The photograph is taken after 20 hr., at which time equilibrium has been established. In order of increasing density, there is DNA from *Clostridium perfringens* (often used as a standard in such work) and different samples of *E. coli* DNA. The first is normal *E. coli* DNA, followed by nitrogen-15-labelled; deuterated; both nitrogen-15 labelled and deuterated; and finally quickly cooled, nitrogen-15 labelled, deuterated DNA

Fig. 1 shows a photograph and tracing of DNA bands in a cæsium chloride density gradient. These illustrate some of the samples labelled with heavy isotopes that have been prepared from *E. coli*. In the deuterated DNA, all deuterium bound to carbon should not exchange with the hydrogen of the water of the physiological saline in which the DNA is isolated. The buoyant density of the DNA in cæsium chloride should thus remain exactly the same after a few months in this solution and even after extensive exposure to temperatures up to 100° C. This has, in fact, been found, eliminating the possibility that slow exchange may take place after isolation of DNA. The quickly cooled, thermally denatured DNA is 0·015 gm./c.c. heavier than the native ^{15}N-deuterated sample. This is the same increase as has been reported for unlabelled DNA (ref. 6).

Table 3 lists the molecular weights of some of the monomer units in the cæsium salt of normal DNA and that labelled with heavy isotope. The densities calculated from the percentage increase in molecular weight due to labelling *E. coli* DNA are 1·724 gm./cm.^{3} for nitrogen-15 substitution and 1·745 gm./cm.^{3} for both nitrogen-15 and deuterium substi-

Table 2. BUOYANT DENSITY OF LABELLED AND UNLABELLED DNA IN CÆSIUM CHLORIDE

Organism	Normal	DNA density (gm./c.c.)

* Cells grown in the medium containing 90–95 per cent D_2O plus $^{15}NH_4Cl$ and the density of the heavy DNA determined directly on a whole-cell lysate. Determinations on other samples were on purified DNA preparations.

Table 3. MOLECULAR WEIGHTS OF MONOMER UNITS OF DNA LABELLED WITH HEAVY ISOTOPE

	Adenine	Thymine	Guanine	Cytosine
Base	134	125	150	110
^{15}N base	139	127	155	113
Deuterated base	138	130	154	114
Deuterated base—exchangeable deuteriums	136	129	151	112
Deoxyribose phosphate	178	178	178	178
Deuterated deoxyribose phosphate	185	185	185	185
^{15}N nucleotide (cæsium salt)	450	438	466	424
Deuterated nucleotide—exchangeable deuteriums (cæsium salt)	454	447	469	430

tution. Since hydrogens bound to oxygen or nitrogen exchange rapidly with water during the isolation of DNA from the bacteria grown in the heavy water medium, the exchangeable hydrogens are not included in the increase of density. It is also assumed that there is no change in volume of the molecule on substitution of the heavy isotope. The predicted density shift for substitution of nitrogen-15 has been observed for the three samples listed in Table 2. Thus far, using the glycerol-lactate medium, it has not been possible to obtain 100 per cent deuterated DNA from *E. coli*. Work is now in progress with a medium containing completely deuterated acetate as the only source of carbon, in order to see whether the DNA isolated will have the theoretical maximum density.

The heavy-labelled DNA prepared by the procedure outlined here has been used extensively in physical chemical studies of strand separation and recombination and in the formation of 'hybrid' DNA molecules. Results of this work will be reported soon by C. L. Schildkraut, J. Marmur and P. Doty. The procedure described can, of course, be adapted for other purposes, such as preparing 'heavy' whole cells, phage, proteins, RNA and other cell constituents.

We are indebted to Prof. Paul Doty for numerous helpful discussions and constant encouragement. The advice and aid of Dr. D. M. Green are gratefully acknowledged. This investigation was supported by a research grant (*C*-2170) from the National Cancer Institute, National Institutes of Health.

NATURE OF THE RIBOSOMES PRESENT IN BACTERIA AND YEAST: A RE-APPRAISAL

By T. J. BOWEN, DR. S. DAGLEY, DR. J. SYKES* and DR. D. G. WILD

Department of Biochemistry, University of Leeds

RIBONUCLEOPROTEIN particles ('ribosomes') appear to form a major constituent of bacterial cytoplasm, and the early work of Schachman, Pardee and Stanier[1], using the ultracentrifuge, showed that ribosomes were responsible for two fast-moving boundaries (29*S* and 40*S*) seen in schlieren diagrams. Tissières and Watson[2] worked with isolated preparations and found the sedimentation coefficients of these particles to be 32*S* and 51*S* respectively when corrected to 20° C. and zero concentration, and we shall refer to them as the '30*S* (or 50*S*) ribosomes'. Ribosomes are also present in animal and plant tissues[3] and in yeast[4], and are generally believed to be a site of protein synthesis[5]; in animal tissues they are often attached to membranes, but in bacteria they appear free in the cytoplasm.

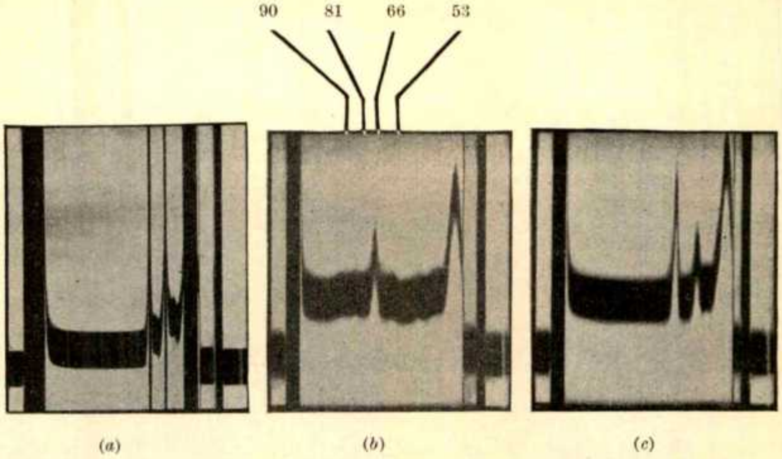
Analytical ultracentrifugation shows that ribosomes isolated from plant and animal sources are larger than the 50*S* ribosomes of bacteria, although the latter can be made to combine with equal numbers of 30*S* ribosomes to form particles sedimenting at 70*S* when the concentration of magnesium ions is raised and phosphate ions are excluded[2]. Since ribosomes isolated from other sources sediment at 70–80*S*, it seems to be generally assumed that inside bacteria there normally exist particles of this size with specific biochemical functions, and that they are liable to dissociate unless special precautions are taken. Accordingly, when cell-free extracts are prepared from disrupted bacteria for ultracentrifuge examination, it is usually the practice to extract with 2-amino-2-hydroxymethyl propane-1 : 3-diol (*tris*) buffer containing magnesium acetate to 'stabilize' the ribosomes. The fact is often ignored that 70*S* ribosomes may be produced from smaller ones by the method of extraction: originally they may not have been present inside the intact cells.

Three fundamental questions concerning ribosomes require attention. (1) Is the ribonucleoprotein of the living cell present as particles ? (2) If so, what are the sizes of bacterial ribosomes ? (3) Is some ribosomal function dependent on size, so that a 70*S* ribosome plays a vital part in metabolism for which smaller ribosomes cannot be substituted ? As regards

---

* Present address: Department of Biochemistry, University of Sheffield.

(3), it has been shown[6] that the sizes of ribosomes in bacterial extracts are greatly affected by concentrations of certain salts in the media from which the cells are harvested prior to disruption. Intracellular concentrations of normally metabolizing bacteria do not appear to be so regulated as to preserve intact the 70*S* ribosome; accordingly, particles of this size would not be essential for normal metabolism, although they may well exist when intracellular conditions are favourable. As regards (1), Swedish electron microscopists[7] have produced evidence that all the particles may be formed by precipitation of ribonucleoprotein during the preparation of materials for examination. Certainly, if the ribonucleoprotein in the living cell were not 'rolled up' into particles, the RNA might be accessible and its function as a template in protein synthesis would be easier to visualize; but any possible connexion between particle size and metabolic function would remain obscure. The present investigations were undertaken to answer question (2).



(*a*) (*b*) (*c*)

Fig. 2. Schlieren diagrams: sedimentation to the left; centrifugal field 187,000*g*. (*a*) Protein concentration, 6 per cent. Sedimentation coefficients (uncorrected) of leading boundaries, 21*S* and 14·5*S* respectively; these are due to 50*S* and 30*S* ribosomes. Photographed at 16 min. (*b*) Protein concentration 1 per cent in *tris* buffer containing 10^{-2} *M* magnesium acetate. The numbers above the photograph (at 8 min.) give uncorrected sedimentation coefficients in Svedberg units. (*c*) Protein concentration 1 per cent in phosphate buffer ($1{\cdot}2 \times 10^{-2}$ *M*). Leading boundaries, due to the 50*S* and 30*S* ribosomes, sediment at 43*S* and 27*S*. Photographed at 8 min.

Determinations of ribosomal size are beset with two difficulties: first, the cells are usually disrupted in a medium that may cause immediate dissociation or aggregation; and second, the extract must be further diluted so as to be suitable for ultracentrifugal analysis. We have employed the bacterial press of Hughes[8], in which almost dry pastes may be disrupted, and have examined the whole crush, including debris, in a cell of light-path of only 3 mm. which permits examination at a dilution of 1 part by weight of crushed cells to 1 part or less of water or buffer. The viscosity of such an extract, however, is so great that a particle cannot be identified from a single sedimentation coefficient: thus the 50*S* ribosome may sediment at about 20*S*. We therefore determined sedimentation coefficients for the faster boundaries at a series of dilutions and plotted them against the protein concentrations of extracts (Fig. 1). The leading boundaries in Fig. 2*a* could then be shown to be due to the 50*S* and 30*S* ribosomes, since these sedimentation coefficients were given by extrapolation to zero concentration. No boundary due to a ribosome sedimenting faster than this is seen in Fig. 2*a*, and this result was also obtained when other concentrated crushes of *Esch. coli* and *B. cereus* were examined. In two experiments a very small peak, possibly due to a 70*S* ribosome, was seen. Phosphate buffer ($1{\cdot}2 \times 10^{-2}$ *M*, *p*H 7) was used to prepare extracts in most cases, but similar results were obtained using water.

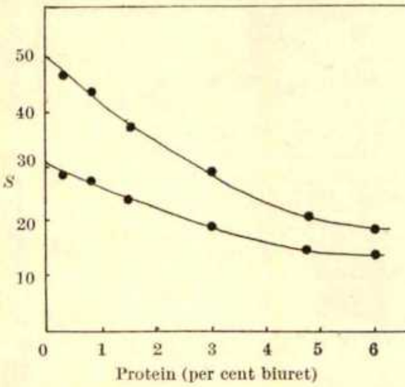


Fig. 1. Sedimentation coefficients (uncorrected) of the larger ribosomes in suspensions of disrupted cells of *Esch. coli*. Rates of sedimentation were measured at a series of dilutions in phosphate buffer ($1{\cdot}2 \times 10^{-2}$ *M*, *p*H 7)

When disrupted bacteria were extracted with 10^{-2} *M tris* buffer containing 10^{-2} *M* magnesium acetate, several larger species were present. A schlieren diagram (12 mm. cell light-path) for such an extract, diluted to the protein concentration (1 per cent) which it has hitherto been customary to use, is shown in Fig. 2*b*. It may be contrasted with that for an extract prepared in dilute phosphate buffer containing no magnesium acetate (Fig. 2*c*). This shows the same main features as Fig. 2*a*, where cell constituents were examined at concentrations much closer to those inside living cells. It appears that the practice of adding a high concentration of magnesium acetate (10^{-2} *M*) to all cell-free extracts before examination, in order to 'stabilize' large ribosomes, is arbitrary and may be misleading.

A similar series of experiments has been conducted with *S. cerevisiae*, and in this case it was possible to examine the juice from crushed cells in the 3-mm. cell without further addition of liquid. From dilution experiments it emerged that the principal (leading) boundary was due to an 80*S* ribosome, as reported for dilute extracts by Chao and Schachman[4]. It therefore appears that the main ribosome (50*S*) normally present in the strains of *Esch. coli* and *B. cereus* that we have studied is of different size from that of yeast (80*S*) or mammals.

Addendum. Very recent work[9] shows that particles from *Esch. coli* sedimenting at 70*S* incorporate amino-acids. In amount, they constitute less than 10 per cent of the total ribosomes and differ from 70*S* ribosomes in so far as they do not appear to be formed from 50*S* and 30*S* ribosomes and are not sensitive to changes in concentrations of magnesium ions. It is therefore more readily understood why the metabolism of bacteria remains unaffected by salt concentrations that can cause profound changes in the distribution of their ribosomes[6]. However, the function of most of the ribonucleoprotein responsible for ultracentrifuge schlieren diagrams of crude extracts remains obscure.

A PLAQUE METHOD FOR ASSAYING SOME VIRUSES ISOLATED FROM COMMON COLDS

By ROSEMARY PARSONS and DR. D. A. J. TYRRELL

Medical Research Council Common Cold Research Unit, Salisbury, Wilts

WE have recently described the isolation of some hitherto uncultivable viruses from human beings suffering from common colds[1-3]. Many more strains have now been isolated[4]. In order to study the properties of a few of these in some detail a simple and precise method of assay was required and methods based on counting plaques have obvious advantages. This article reports the development and testing of such a technique.

In preliminary experiments we attempted to produce plaques by methods closely resembling those originally described by Dulbecco[5]. However, a marked cytopathic effect did not appear in stationary cultures, and the cell sheet did not survive under agar with the roller tubes and media used. An attempt was therefore made to count the focal lesions (Fig. 1) described earlier as the first stage in the cytopathic effect of viruses of this type[3]. This has previously been done with herpes virus[6], vaccinia virus[7] and using enteroviruses in tube cultures[8]. The foci or plaques were counted over the whole cell sheet in every tube using a total magnification of 30–40 ×. Countable plaques were observed with two strains of virus (*P.K.* and *H.G.P.*) which produce a cytopathic effect in monkey kidney cells and in human amnion cultures. Plaques were also counted with viruses growing in human kidney cells; the plaques were, however, more difficult to count because the cell sheet was less uniform than with monkey kidney cells. For practical reasons nearly all the remaining experiments were performed with *H.G.P.* virus in cultures of monkey kidney cells.

The tissue cultures used were secondary cultures of rhesus kidney cells. Between 30,000 and 40,000 cells were inoculated into stationary tubes in 0·5 ml. of a medium consisting of 5 per cent calf serum and 0·5 per cent lactalbumin hydrolysate in Hanks's saline containing 0·03 per cent sodium bicarbonate and 100 units of penicillin, 100 γ of streptomycin and 20 units of mycostatin per ml. Cultures were incubated at 36° C., usually for 12–24 hr. until ready for use. Inoculation took place after the medium had been changed to 1·5 ml. of one containing 2 per cent calf serum and 0·25 per cent lactalbumin hydrolysate, the other constituents remaining the same. After inoculation cultures were incubated at 33° C. in a roller drum. The virus strains had been isolated as described elsewhere[1-4]; *p*H determinations were made with a glass electrode instrument. The plaque count was only calculated from groups of cultures in which every tube had a countable number of plaques or no plaques. Ten-fold or 3·2-fold dilutions were usually employed so that it was possible to combine the results of several dilutions, 3–5 tubes being inoculated with 0·3 ml. of each dilution.

Statistical Aspects of Microplaque Counts

The number of plaques counted by two observers usually agreed quite closely, but there were difficulties at times because of lack of experience in searching the cell sheet systematically. Other discrepancies were reduced when it was agreed (*a*) that a focus must contain about 10 cells to be scored as a plaque, (*b*) that counts of more than 15–20 plaques be excluded. The exact number depends on the degree of compact-

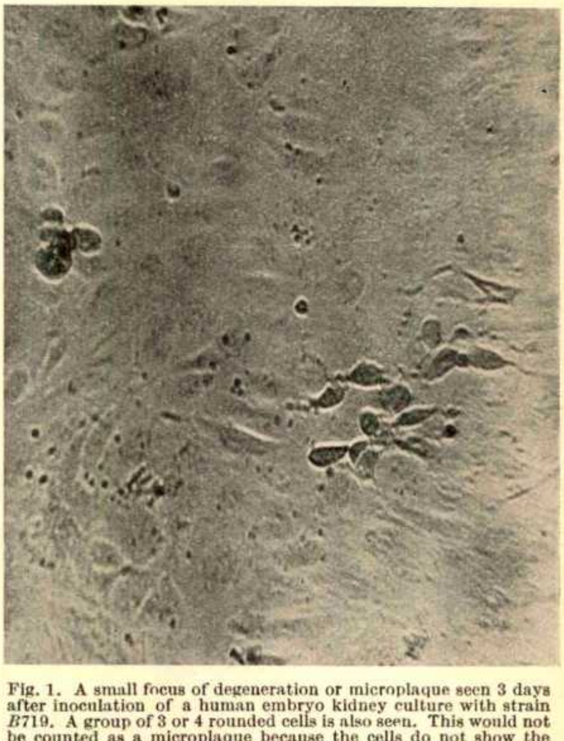

Fig. 1. A small focus of degeneration or microplaque seen 3 days after inoculation of a human embryo kidney culture with strain *B*719. A group of 3 or 4 rounded cells is also seen. This would not be counted as a microplaque because the cells do not show the typical changes induced by the virus. (Unstained × 240)

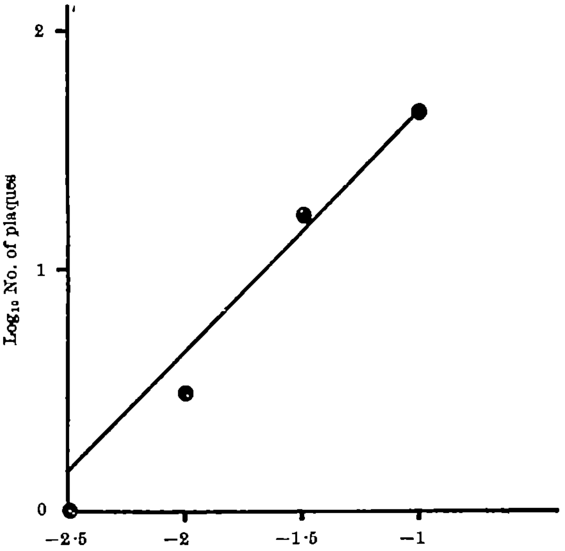

Fig. 2. The relationship between plaque count and the concentration of virus in the inoculum

ness of the plaques, which differs between batches of monkey kidney cells.

In numerous experiments it was shown that until three days the number of plaques occurring was directly proportional to the concentration of virus inoculated. An experiment of this type is shown in Fig. 2. In a χ^2 test applied to the original data the deviations from expectation were found not to be significant.

The distribution of plaque counts was compared with that to be expected on the basis of a Poisson distribution. Fifty tubes were inoculated with a pool of virus diluted 1/100. As can be seen from Fig. 3, the number of plaques at three time-intervals after inoculation agreed well with the distribution calculated from the mean number of plaques per tube. The deviations from expectation were tested by the χ^2 test, and in each case P was greater than 0·1. After three days the number of plaques increases in all tubes near the end-point while negative tubes remain negative We assume that 2–3 days following inoculation an increasing proportion of the virus particles which have become attached to the cells are able to produce visible plaques, and that later plaques are secondary to the earlier plaques. In some experiments the plaque count at three days was compared with the titre of virus as judged by the 50 per cent end-point method used before[3]. The highest plaque count obtained before the distribution became non-Poissonian seemed to be equivalent to the 50 per cent infectivity end-point method.

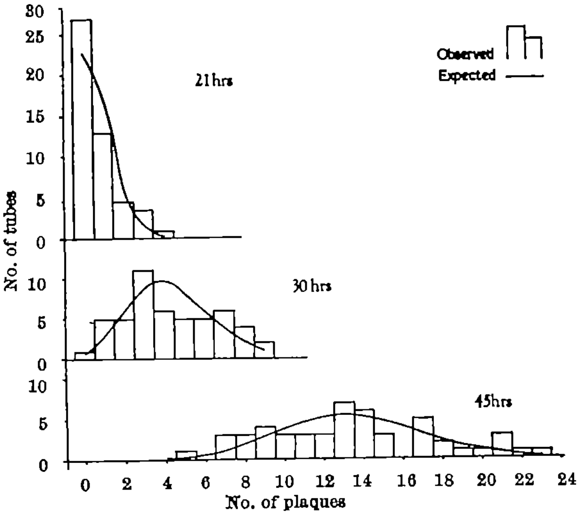

Fig. 3. The number of microplaques counted compared to those expected according to the Poisson distribution

It was shown that if *H.G.P.* virus was mixed before inoculation with a specific hyperimmune antiserum (prepared in a rabbit) the plaque count was reduced· These experiments will be reported in full later.

Optimal Conditions for the Production of Microplaques

(*a*) *Temperature and pH of medium.* It was discovered that the conditions previously found necessary for the production of a general cytopathic effect were also necessary for the appearance of the maximal number of microplaques. With a strain of *H.G.P.* well adapted to monkey kidney cultures, the temperature was found to affect the plaque count, as can be seen from Table 1. Similar results were obtained when virus-infected nasal washings were used as the inoculum.

Table 1. Effect of Temperature of Incubation on the Number of Plaques Developing

Inoculum	Day of reading	Plaque count on cultures incubated at		
		30° C.	33° C.	36° C.
Virus passed 5 times in human embryo kidney and 8 times in monkey kidney cells	Day 2	12	1,200	190
	Day 3	1,400	14,000	150

We wished to know if changes in bicarbonate concentration were important in themselves or because of changes they induced in the *p*H of the medium. Titrations were therefore set up in parallel cultures maintained in media containing various concentrations of bicarbonate as buffer, or else sodium phosphate buffer. The number of plaques appearing was counted and the *p*H of the medium in each case was estimated. The *p*H usually dropped about 0·3 unit between the beginning of the experiment and the time of reading, but the change was greater in cultures buffered with bicarbonate and less in tubes buffered with 0·05 *M* phosphate. The results of two such experiments are shown in Fig. 4. It seems that the *p*H rather than the concentration of bicarbonate affects the plaque count and that optimal conditions were obtained when the medium had a mean *p*H of 7·0–7·4. The *p*H of the medium at the end of the experiments showing optimal results ranged from 6·9 to 7·1. This was achieved by adding phosphate buffer *p*H 7·14–7·69 at a final concentration of 0·05 *M* to a medium without bicarbonate.

(*b*) *Volume of inoculum.* In several experiments, stationary cultures at 33° C. were overlaid with a standard dose of virus contained in various volumes of medium. 4 hr. were allowed for adsorption of virus ; after this the inoculum was poured off and the cultures were washed before fresh medium was added and the tubes were rolled (Table 2). It can be seen that high titres were obtained with rather small volumes of fluid but the titres were no higher than those obtained when we used 1·5 ml. and rolled the cultures immediately following inoculation. The

Table 2. Effect of Inoculum Size on the Plaque Count

Size of inoculum	0·1	0·3	0·6	0·9	1·5 ml.
Plaque-forming units/ml.	1,200	1,200	1,100	840	1,300

reason for this is not understood as we expected the virus to become attached to the cells most successfully when small volumes were used ; possibly even a short period under stationary conditions reduces the susceptibility of the cells to virus.

(*c*) *Time of exposure to inoculum*. Cultures were inoculated with dilutions of virus and incubated under standard conditions. At intervals the medium was poured off sets of culture tubes (donor tubes) and inoculated to other sets, to ascertain how much virus had disappeared from the medium. In some experiments the donor tubes were washed or donor tubes were used which contained no cells. Some typical results are summarized in Fig. 5. This indicates that 80–90 per cent of virus added to the tubes is rapidly adsorbed. However, the virus has to be left in contact with the cells for 2–4 hr. in order to give maximal plaque counts. It is probable that much of the virus which disappears from donor tubes is adsorbed to the glass of the tubes since virus disappears from dummy donor tubes which contain no cells.

Discussion

Since the experiments described above were performed it has been found that the microplaque method can be readily applied to the measurement of relative virus concentration for various purposes. It has also been used to measure quantitatively the neutralizing activity of sera and nasal secretions, and to assay the effect of interferon on monkey kidney cells[9]. We are also using it to assess the effect of adverse conditions such as high temperature and pH on different phases of the growth-cycle. The main difficulty of the test is the necessity to read the cultures at what often prove to be awkward times, since if cultures with, say, 1 or 2 plaques are left for 24 hr. they may be unreadable because the plaques are confluent. In addition, with ill-adapted viruses or with uneven batches of tissue cultures the results may be less satisfactory than those reported here. Nevertheless, since using this technique we have been able to accumulate, with the use of relatively small amounts of tissue culture cells, more precise data than was previously possible.

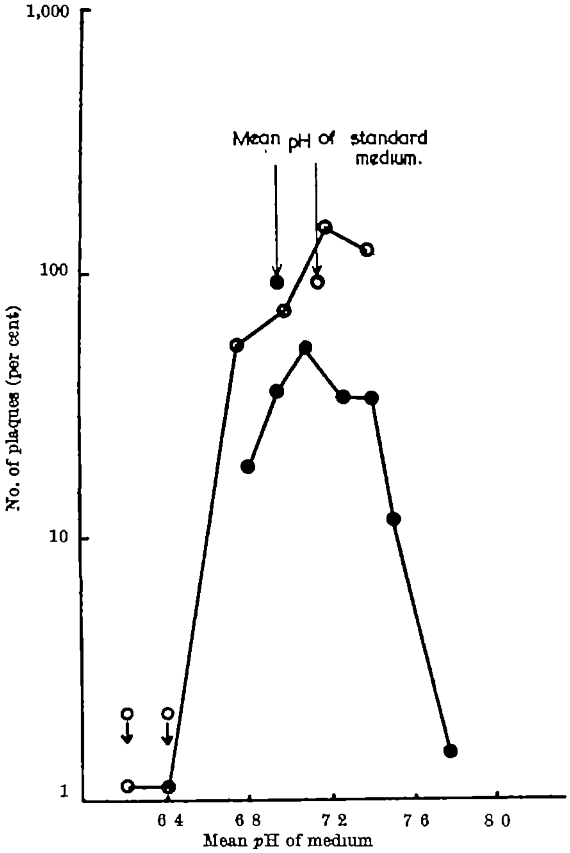

Fig. 4. The number of plaques developing in tissue cultures containing media buffered with phosphate at various pH's—expressed as a percentage of the number of plaques in cultures containing the standard amount of sodium bicarbonate (0·03 per cent). ○, exp. 1 ; ●, exp. 2.

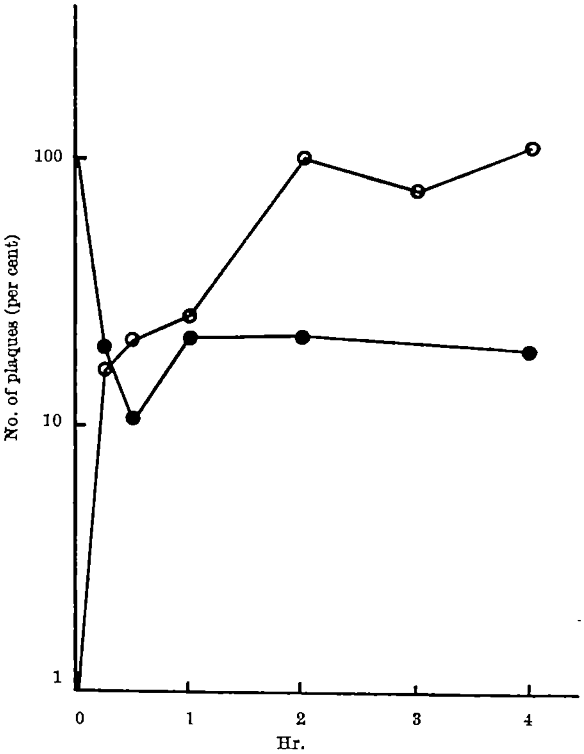

Fig. 5. ○, Number of plaques appearing in a series of dilutions when the inoculum was removed at various times, as percentage of plaques found when the inoculum was not removed , ●, residual virus recovered from the medium of dilution tubes, assayed by transfer to fresh tissue cultures, and expressed as percentage of plaques found when the inoculum was not removed. The amount of virus left in the medium was proportional to the concentration of virus inoculated

We wish to thank Mr. K. Allner for the photomicrograph and Mrs. P. A. Palmer for technical assistance.

FLUORESCENCE AND HÆMOLYTIC ACTIVITY OF TUMOURS AND NORMAL TISSUES OF THE *C3H* MOUSE

By Dr. ERIC PONDER and RUTH V. PONDER
Nassau Hospital, Mineola, New York

LYSINS have been extracted from normal mouse tissue, from mammary carcinomas of female *C3H* mice[1], and from lymphomatous glands of *AKR* mice[2]. They have been partially identified as C-18 fatty acids[3], such as oleic, ricinoleic or related fatty acids, for example, the cytolysin found in the royal jelly of bees, 10-hydroxydecenoic acid, lethal for leucæmic and ascitic tumour cells[4], the antibiotic C-18 fatty acid found in royal jelly (also 10-hydroxydecenoic acid)[5], and the as yet unidentified fatty acid in the microsome fraction of guinea pig liver cells[6,7].

This communication is concerned with measurements of the amount of fatty acids found in the normal tissues and the tumours of *C3H* mice, using fluorescence methods and hæmolytic titrations.

Mammary tumours are dissected from the white tumours of *C3H* mice after the animals have been bled by cardiac puncture. About half the material, minced with scissors, is weighed, dried to constant weight at 60° C. and re-weighed. This gives the dry material of the tumour.

The remaining half of the wet mince is transferred to the thimble of a micro-Soxhlet apparatus and is extracted for 2 hr. with 25 ml. of hot benzene which is made up to 50 ml.; this gives the unknown X which contains the C-18 fatty acids and other substances extracted by hot benzene from a known weight of wet tumour mince.

A standard $M/100$ solution ($= 2{\cdot}8$ mgm./ml.) of ricinoleic or oleic acid in 50 ml. of benzene is prepared, and also a colour-reaction mixture R; this consists of 5 ml. of saturated rhodamine B in benzene plus 10 ml. of 2 per cent uranyl nitrate in benzene. This reaction-mixture is used to give the fluorescence described by Feigl[8] for the higher carboxylic acids, for which, however, it is not altogether specific. To three square 1 ml. cuvettes which fit the Photovolt Corporation's fluorescence meter, one adds 1 ml. of the standard S, 1 ml. of the unknown X, and 1 ml. of benzene (to serve as a blank b). The fluorescence of each is read; they are not the same, because benzene-extracted tissues contain fluorescent substances other than C-18 fatty acids. The fluorescence of the blank is subtracted from that of the unknown, and the result is divided by the fluorescence of the standard with that of the blank subtracted. This gives F_1. To each cuvette is added $0{\cdot}75$ ml. of the reaction mixture, and after stirring with an air jet, the fluorescence of each cuvette is read. The fluorescence of the unknown, with that of the blank subtracted, is divided by the fluorescence of the standard with that of the blank subtracted. This gives F_2; $(F_2 - F_1)$ gives the fluorescence due to the higher carboxylic acids. The primary filter in the fluorescence meter transmits the 365 mμ mercury line, and the secondary filter transmits the 410–480 mμ band. The Photovolt Corporation's photomultiplier, the search unit of which is attached to the fluorescence meter, should operate at its highest multiplication, which is about 10^5.

The fluorescence of the standard is set by the photo-attenuator at some figure between 10 and 30 on the photometric scale of the photomultiplier. Since the concentration of C-18 acids in the standard is $M/100$, $2{\cdot}8\ (F_2 - F_1)$ gives the concentration in mgm./ml. of the higher fatty acids in the unknown. The dry weight of the material in the mince is known, and so the amount of C-18 fatty acid contained in 1 gm. of dried mince can be calculated. The same method can be applied to tissues of any normal or tumour-bearing animal.

Care must be taken that fatty acids from the hands, etc., are not introduced into the standard, the unknown, and the blank. The inhalation of benzene during pipetting is dangerous. The photomultiplier and fluorescence meter are apt to be unstable unless warmed up for 30 min., and the primary shutter of the fluorescence meter must be kept closed until the blank, the standard, or the unknown are in place in the cuvette holder; the primary shutter is then opened for a few seconds, and the fluorescence is read. If the apparatus is used in this way, it is stable and the relation between fluorescence and concentration of C-18 fatty acid is almost linear. When the fluorescence of the unknown is much greater than that of the standard, as in liver and lung, the benzene extracts should be diluted so that the fluorescence meter can be used very nearly as a null instrument.

The standard S used in the fluorescence measurements is a $M/100$ solution of ricinoleic (or oleic) acid in benzene. It contains $2{\cdot}8$ mgm./ml. of fatty acid and 60×10^{17} fatty acid molecules per ml. The expression $(F_2 - F_1) = 280/wd.(X' - b)/(S' - b)$ gives the quantity of higher fatty acids in mgm./gm., where d is the percentage of dry material in the unknown and w is the weight (gm.) of the benzene-extracted tissue. This often gives large values, for example, 5–50 mgm./gm. of dry tissue.

If 1 ml. of the benzene solution of the unknown is dried in a current of air and the fatty acid taken up in m ml. of phosphate buffer at pH 7, its lytic activity can be compared with that of S, $S/2$, $S/4$, etc., treated similarly. If the unknown has the same lytic activity as S/n, the lytic activity of the material in the unknown X is S/mn. The value is usually small, for example, 70 γ/ml. or less, which is partly due to fatty acids not being soluble at pH $7{\cdot}0$. They are probably soluble, however, in the lipoproteins of the surface of the red cell.

Table 1. APPARENT CONTENT OF C-18 FATTY ACIDS IN DRY WEIGHTS OF TISSUE

Normal *C3H* males		Tumour-bearing *C3H* females			
Liver	Lung	Tumour	Liver	Lung	Muscle
22·4 ± 2·2	29·2 ± 3·1	4·5 ± 1·1	37·8 ± 5·2	39·4 ± 3·7	2·2 ± 0·05

The ratio of the value 2·8 ($F_2 - F_1$) found by fluorescence to that found from hæmolytic activity, for example, 5–50 mgm./ml. compared with 70 γ/ml., or at least 70 to 1, might provide the approximate ratio of the total fatty acid in the system to the fatty acid bound at the red cell surface were it not that the surface can become saturated with fatty acid molecules, arranged end-on in the first instance. The mean surface area of the red cell is $1 \cdot 67 \times 10^{10}$ Å.^{2}, and if the number of cells per ml. is 10^8, the total cell surface is $1 \cdot 67 \times 10^{18}$ Å.^{2}. The cross-sectional area of a fatty acid molecule is about 10 Å.^{2}, so $1 \cdot 67 \times 10^{17}$ Å.^{2} of the cell surface can be covered by a continuous film of fatty acid. The standard system contains 60×10^{17} of fatty acid, and so saturation occurs when about 80 γ/ml. is bound. If a system contains more lysin, the bound lysin probably remains at about 80 γ/ml., and the curve obtained by plotting the free fatty acid against that bound, both in γ/ml., shows a discontinuity at the saturation value. If the system contains less lysin than the saturation value, the quantity of lysin bound is proportionately less. This is in agreement with the results of radioactivity measurements with oleic acid[9]. (The fatty acid was wrongly referred to in this paper as its sodium soap, which it is not at *p*H 7; this makes little difference to the conclusion.)

The mean values, with the standard error of the mean, for the C-18 fatty acids in mgm./gm. dry weight of normal liver, normal lung, tumours, livers, lungs and muscle of tumour-bearing mice are shown in Table 1. The values do not have great precision, partly because the standard deviations are large, partly because a difference ($F_2 - F_1$) is a part of the calculation, and partly because the quantity of blood in the tumours and in the tissues, although small because the mice are bled, is not measured. Even heparinized blood when extracted with benzene and treated with the colour reagent gives a small fluorescence (1·0–1·5 mgm./gm. of dry weight) and some fraction of this, depending on the quantity of blood which the tumours or tissues contain, ought to be subtracted. The values for the livers and lungs of the tumour-bearing females are, however, significantly greater than the corresponding values for the males.

The most significant finding is that, at *p*H 7–8·5, homogenates of *C3H* mouse tumours or of the glands of *AKR* lymphomatous mice[2] are usually more lytic than homogenates of normal mouse liver and lung, while benzol extracts of normal mouse liver and lung apparently contain 4–12 times the amount of C-18 (or higher) fatty acids contained in benzene extracts of the tumours, and as estimated by fluorescence. One explanation is that lytic fatty acids are bound to a greater extent to inhibitors in the tissue homogenates than in the tumour homogenates. Another explanation is that normal mouse liver and lung contain small amounts of non-lytic, benzene-soluble, and very fluorescent substances which enter into the reactions for C-18 fatty acids, whereas these substances scarcely occur at all in tumours.

Contribution of Vitamin A and Vitamin A-like Substances

There is some evidence that mouse liver and lung contain two kinds of benzene-soluble substances (see preceding communication). The first are C-18 fatty acids, which fluoresce on the addition of rhodamine *B* and uranyl nitrate when they are excited in the ultra-violet. These acids are hæmolytic, and exist both in normal mouse liver and lung and also in the mammary tumours of the *C3H* mouse. The second kind of substance is also fluorescent, but is non-lytic; it occurs in mouse liver and lung, but not in mouse mammary tumours. It is possibly vitamin A or a related substance. Its concentration and also that of the C-18 fatty acids can be estimated by a combination of fluoroscopy and ultra-violet spectrophotometry, since vitamin A shows an absorption maximum at 330 mμ, while the C-18 fatty acids show absorption between 280 and 285 mμ and not at 330 mμ.

The procedure is as follows: With a Cary No. 11 recording spectrophotometer, the optical density *D* at 330 mμ is found for a series of concentrations of vitamin A in benzene. Beer's law is obeyed between 1 γ/ml. and 50 γ/ml. About 1 gm. of liver is extracted with benzene in a Soxhlet apparatus and is made up to 50 ml. with benzene. By spectrophotometry, and using the calibration curve already obtained for the optical density *D* at 330 mμ of different concentrations of vitamin A, the concentration of the latter in the liver extract is found to be *x* in γ/ml. This step enables the value of *D* to be related to the value of the fluorescence *F*.

The fluorescence *F* of various concentrations of vitamin A in benzene (1 γ/ml., 5γ/5 ml. 10γ/10 ml., etc.) is found with the Photovolt Corporation's fluorescence meter, and a small value for a blank *b* is subtracted from each. The fluorescence of the liver extract is found similarly. *b* being again subtracted, and the extract being diluted suitably with benzene. The fluorescence *F* can then be related to the optical density *D*, the relation being $F/D = 15 \cdot 4 \pm 1 \cdot 0$. Note that the units for both *F* and *D* are γ/ml. wet weight. This method of estimation can be applied to extracts of male and female mouse livers (the females usually being tumour-bearers in these experiments), to extracts of tumours, etc.

The values of 2·8 (F_2–F_1) are then found for extracts of male and of female livers, tumours, etc., as described above; these values are those for the C-18 fatty acid content, and the unit is now mgm./ml. wet weight. In the case of each tissue extract, the value for the vitamin A content (in γ/ml.) is subtracted from the much larger value for the C-18 fatty acid content (in mgm./ml.); the difference can then be expressed in mgm./gm. dry weight, if desired. The concentration of the lytic C-18 fatty acids in mouse liver and lung is always at least 99 times greater than that of vitamin A or vitamin A-like substances, and so it can be concluded that the principal reason for homogenates of *C3H* mouse tumours being more lytic than homogenates of normal mouse liver or lung, although benzol extracts of the latter seem to contain 4–12 times the amount of C-18 fatty acids contained in the benzene extracts of the mouse tumours (estimations by fluorescence), is that the reaction which estimates the lytic C-18 fatty acids also reacts with a very much smaller amount of very fluorescent substances, such as vitamin A.

A number of subsidiary points have been established during these investigations. (1) The vitamin A concentration of *C3H* mouse tumours is very small, that of the livers of male mice is about 1 γ/ml., but that of the livers of tumour-bearing female mice is about ten times greater. (2) The concentration of vitamin A in benzene extracts of mouse livers is not reduced by shaking with 0·1 *M* sodium hydroxide, that is, the substance with an absorption maximum at 330 mμ is either not a vitamin-A acid, or else is strongly bonded to other benzene-soluble substances. (3) Some of the benzene-soluble substances present in mouse liver are taurocholates (absorption between 281 and 293 mμ), tripalmitates (absorption at 281 mμ), and cholesterol, a possible inhibitor (absorption between 280 and 295 mμ); linoleic acid, a typical C-18 hæmolytic fatty acid, has its maximum absorption at 275 mμ in a 1 per cent solution in benzene, and does not absorb at 330 mμ. Present observations throw no light on the extent to which lytic fatty acids are bound to inhibitors in homogenates of normal tissue and homogenates of tumours.

SHORTENING OF LIFE AND CAUSES OF DEATH IN MICE EXPOSED TO A SINGLE WHOLE-BODY DOSE OF RADIATION

By Dr. PATRICIA J. LINDOP and Prof. J. ROTBLAT

St. Bartholomew's Hospital Medical College, London, E.C.1

A SYSTEMATIC investigation has been carried out on the reduction of life-span and causes of death in mice exposed at the age of 30 days to a single whole-body dose of 15-MeV. X-rays. 4,604 mice, half of them male and half female, of an inbred *A* sub-strain were used. The animals were randomly divided into ten dose groups (Table 1); one of these, the control group, underwent the procedure of 'sham' irradiation.

Apart from the single event of the exposure to radiation, all irradiated mice were kept to the end of their lives under the same conditions as the control population. The age at death was recorded for each animal, and an attempt made to establish the cause of death at autopsy.

A full description of the experimental technique and a detailed analysis of the results will be published in the *Proceedings of the Royal Society*[1]; in this article we present only a summary of the results and conclusions.

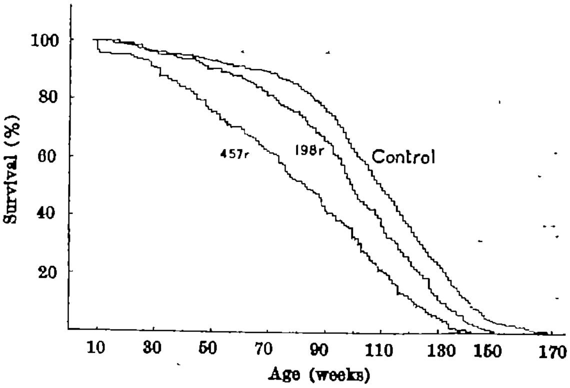

Fig. 1. Survival curves of male mice

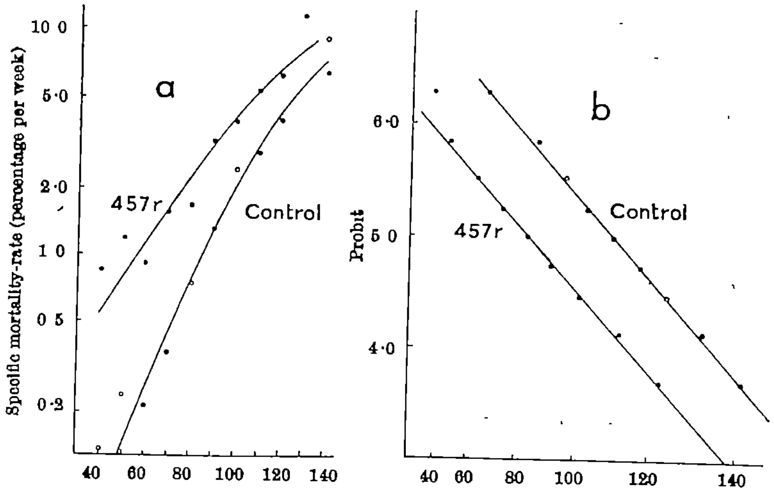

Fig. 2. (*a*) Gompertz plots in 10-week intervals; (*b*) probit as a function of square of age for every decile of the survival curves

Shortening of Life

Survival curves, in which the percentage of the population surviving to a given age is plotted against the age, were drawn for every dose group, counting as 100 per cent the mice alive at the age of 60 days, that is, 30 days after the exposure. Typical survival curves for the male control group as well as for male mice exposed to 198 and 457 r. are given in Fig. 1.

An attempt was made to analyse the survival curves in terms of a Gompertz plot (logarithm of specific mortality-rate versus age). As seen from Fig. 2*a*, the experimental points are rather widely scattered

Table 1. DOSE GROUPS

Dose (r.)	Number of mice	Dose (r.)	Number of mice
0	1,152	457	576
50	576	549	144
98	576	630	140
198	576	703	144
350	576	780	144

and they do not fall on straight lines as might have been expected[2]. On the other hand, a plot of the probit of the percentage survival against the square of age was found to give an excellent linear regression (Fig. 2*b*).

Two effects of radiation are noted from the survival curves: (*a*) a reduction in the median age; (*b*) a small increase in the standard deviation of the distribution of ages at death. We suggest that the latter effect is the result of the greater spread in the ages of onset of different diseases which occurs in the irradiated animals.

We have calculated that this increased spread would give rise to the following variation of the standard deviation with dose:

$$\sigma = [27 \cdot 3 + 0 \cdot 2D + 0 \cdot 001\, D^2$$

where σ is the standard deviation in weeks and D is the dose in roentgens. The observed variation of σ with dose was found to agree closely with this expression.

The main effect of radiation, that is, the shift of the survival curves towards a younger age, was found to be proportional to the dose. If the ages at which the animals from different dose groups reached a given percentage of survival are plotted against the dose, straight lines are obtained. The slopes of these lines are not the same but decrease systematically as one goes from high to low percentages of survival. This is the result of the variation already mentioned of the standard deviation with dose. If a correction for this variation is made, according to the above expression, the slope of all lines becomes the same within the experimental error.

From the displacement of the survival curves relative to that of the control group the amount of life-shortening can be calculated for each dose group. This is plotted against the dose in Fig. 3. It is seen that the points fall closely on a straight line which passes through the origin within the limits of experimental error. The reduction of life-span is thus proportional to the dose, and there is no threshold for this effect.

From the slope of the line the life-shortening is calculated to be 5·66 ± 0·18 weeks per 100 r. Taking into account the relative biological effectiveness of 15-MeV. X-rays (0·81 ± 0·03) this corresponds to 7·00 ± 0·34 weeks per 100 r., if 250-kV. X-rays were used. The relative shortening of life is 38·0 per cent of the median life-span for a dose equal to the *LD*50 (698 r.).

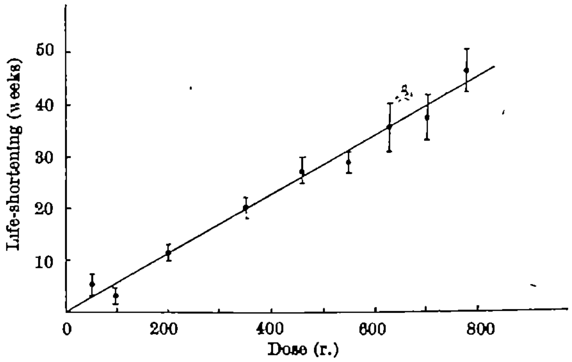

Fig. 3. Shortening of life as a function of dose for mice of both sexes

Separate calculations for male and female mice show a slightly larger life-shortening effect in males than in females, but the difference is within the experimental error.

The life-shortening effect found by us is considerably greater than that observed by other investigators[2]. This may be due to the difference in age at irradiation. We have found previously[4] that at four weeks of age the radiation sensitivity to acute effects is much greater than at other ages. The linear relationship between life-shortening and dose observed

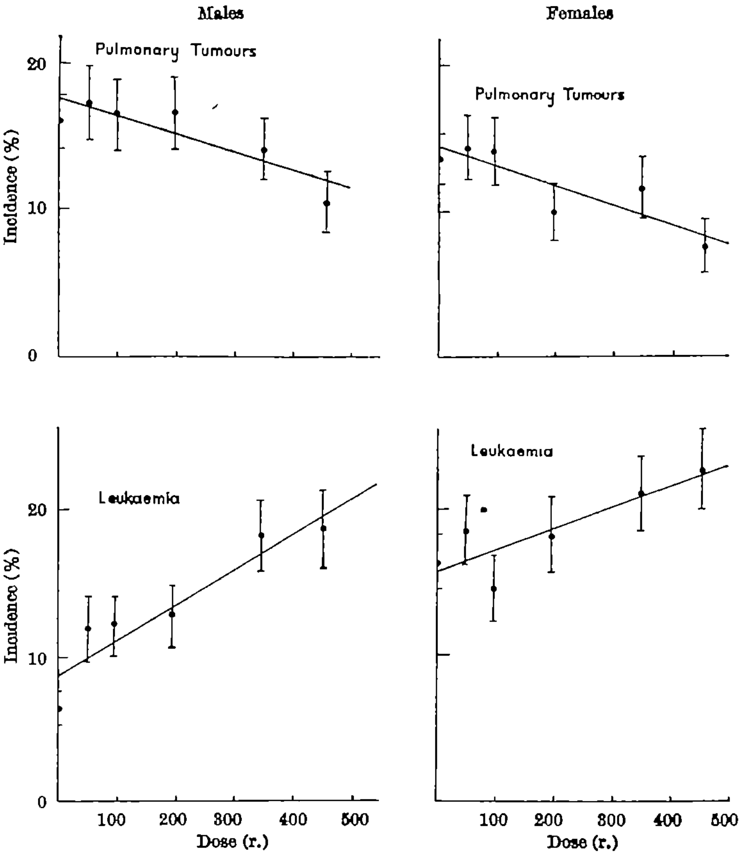

Fig. 4. Percentage incidence of deaths from leukæmia and pulmonary tumours, as a function of dose

Table 2. GROUPING OF CAUSES OF DEATH

Cause	Diseases included
Leukæmia	thymoma, lymphatic and myeloid leukæmia, lymphadenoma, lymphosarcoma
Pulmonary tumours	a few benign adenomata, but mostly adenocarcinomata
Liver tumours	hepatoma, hæmangiomata and secondary deposits from unknown primary tumour
Ovarian tumours	some benign cystadenomata, but mostly granulosa cell tumours
All other tumours	carcinomata or sarcomata not included in the above groups
Pulmonary	degenerative, infective or hæmorrhagic conditions of lung ;
	generalized infection, for example, staphyloccal septicæmia
Renal	mechanical, infective or degenerative conditions in urinary tract
Liver	degenerative, infective or infiltrative conditions of liver
	miscellaneous causes, for example, aneurysm
Intestinal	hæmorrhage, obstruction or infection
Undiagnosed	undiagnosed cause of death, due to lack of visible pathological changes, mouse eaten or autolysed ; this group may include many different diseases

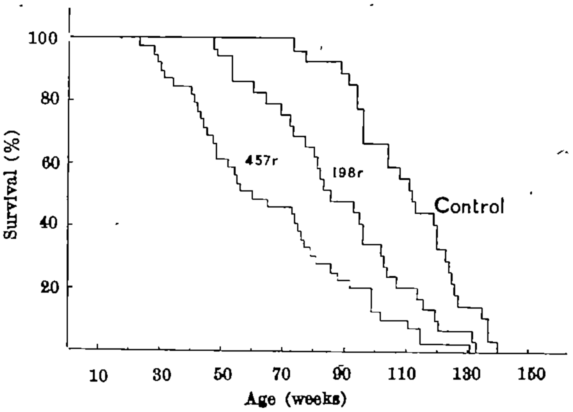

Fig. 5. Age distribution of deaths from leukæmia in male mice

by us, and the lack of a sex difference in this effect, may also be characteristic of the young age at irradiation. Experiments are now in progress to determine the dependence of life-shortening on age at irradiation.

The fact that the corrected survival curves are parallel to each other after the 'plateau' region, suggests that life-shortening is the result of the loss of a few weeks of early life and not of a contraction of the time-scale of the animal's life. From the point of view of survival the irradiated mice behave exactly like their non-irradiated mates of an older age, and only in this sense can one claim that radiation causes premature ageing by an amount proportional to the dose.

Causes of Death

Apart from obtaining a quantitative relationship between shortening of life and dose, the aim of the investigation was to establish whether the reduction of life-span is the result of induction by radiation of certain specific diseases or of an advancement of all natural causes of death. For this purpose a full post-mortem examination has been carried out on each animal which died to try to establish a cause of death, according to certain criteria fixed at the start of the investigation. Random samples of tissues were also taken for histological study. In the final analysis all causes of death were divided into 10 groups (Table 2), which include five tumour and four non-tumour groups. The tenth group, which comprises about 20 per cent of all deaths, contained the cases in which no definite diagnosis could be established.

In view of the much smaller numbers of mice in the highest dose groups, a detailed statistical analysis was carried out only for the six lowest dose groups, 0–457 r.

The percentage incidence of a given cause of death was found, in most cases, to vary very little with dose, but some diseases showed a definite increase and others a definite decrease with dose. The most pronounced absolute changes are shown in Fig. 4 ; these are an increase with dose in the incidence of leukæmia and a decrease in pulmonary tumours. All four plots give reasonably good linear relationships between incidence and dose.

Apart from the change in incidence, the distribution in time of deaths from different causes turned out to be of great interest. 'Survival curves' were drawn for each cause of death in a similar way as in Fig. 1 for deaths from all causes. An example of such a curve, for leukæmia in males, is shown in Fig. 5. From these curves the median age for the occurrence of each disease was determined. A plot of such median ages versus dose is shown in Fig. 6 for the same two diseases as in Fig. 4. Fig. 6 also contains the lines for the median ages at death from all causes. It is seen that while all causes of death were advanced by radiation, some were advanced faster than others ; in particular, leukæmia was advanced more and pulmonary tumours less than the average.

A detailed analysis has shown that there exists a definite correlation between the acceleration of a given

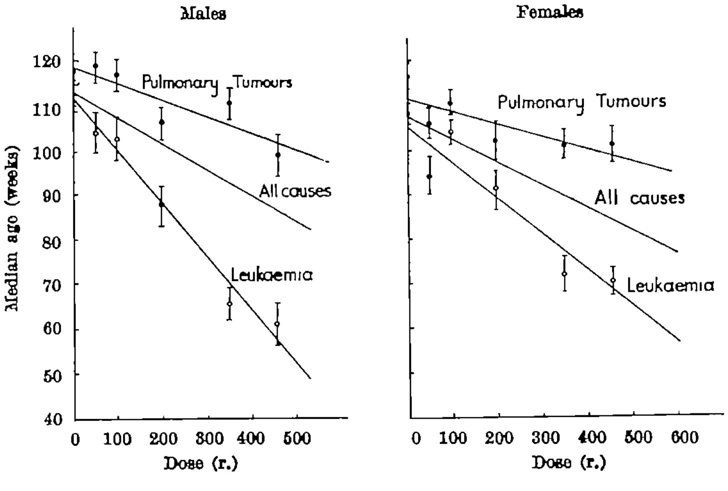

Fig. 6. Median age at death from different causes as a function of dose. The experimental points were omitted for the lines relating to all causes of death

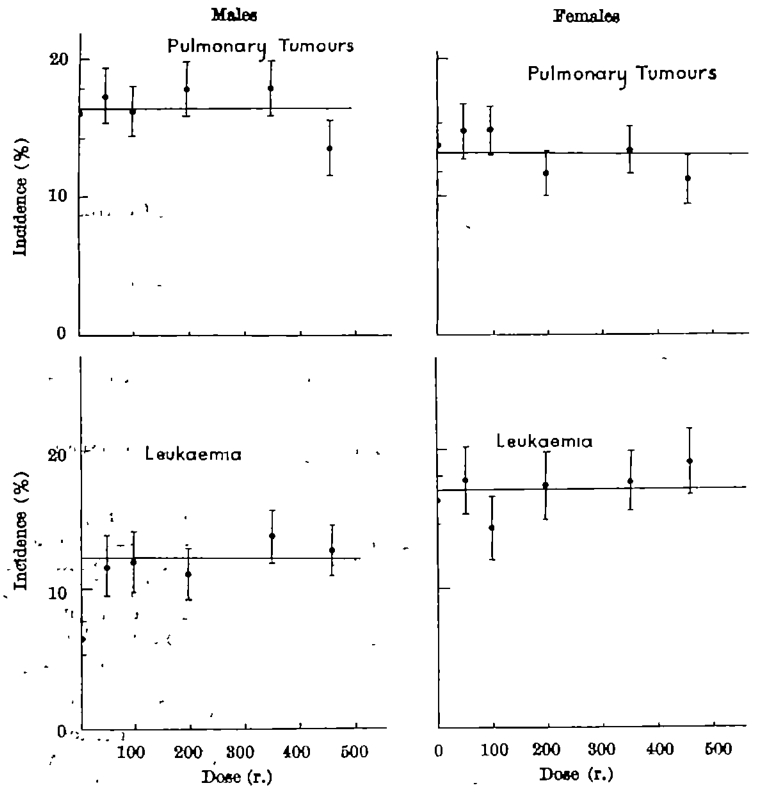

Fig. 7. Percentage incidence of deaths from leukæmia and pulmonary tumours, corrected for the different rates of advancement of these diseases

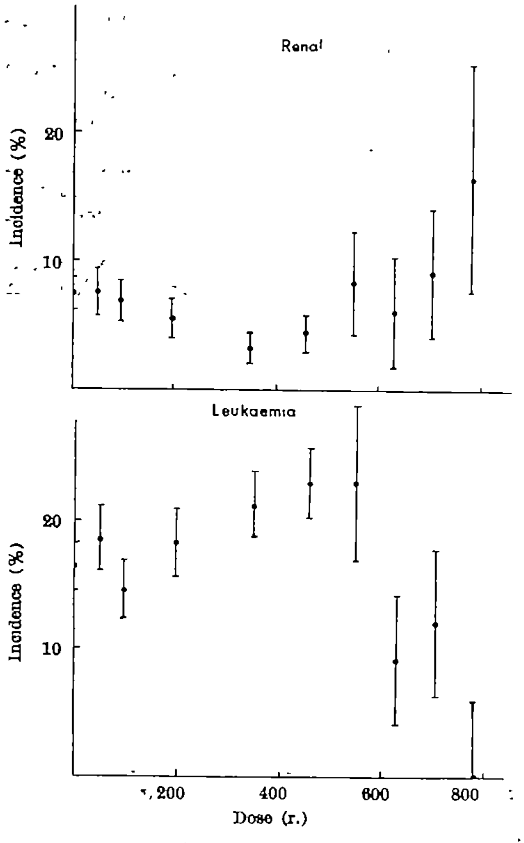

Fig. 8. Percentage incidence of deaths from leukæmia and renal diseases in female mice, showing effect of high doses

cause of death and the rate of change of the percentage incidence with dose. This correlation suggests that the change in incidence is merely the result of the changed times of onset of diseases, since an animal which would have normally died of one disease will die earlier of another disease which is more accelerated by radiation. An actuarial correction was made to take into account the change in time of onset of the different diseases, and the corrected incidences have indeed been found to be independent of dose. This can be seen from Fig. 7, which should be compared with Fig. 4. We conclude, therefore, that the intrinsic probability of any one disease occurring is the same in irradiated as in control animals, the main effect of radiation being an advancement of all causes of death but at different rates. Which disease is more advanced may depend not only on strain characteristics, but also on the age of the animal at irradiation. The pathogenesis of diseases occurring later in life and contributing to death may be laid down at different ages in life. In this investigation, in which the irradiation was given at the age of 30 days, when the hæmopoietic tissue is most active, leukæmia was most advanced by radiation. Exposure at another age may well bring to the fore a completely different disease.

In the high-dose groups another effect was observed, namely, a decrease in incidence of all neoplastic diseases, with a corresponding increase in the incidence of non-neoplastic diseases. This can be seen from Fig. 8, which shows the variation with dose of the incidence of leukæmia and renal diseases. A decrease in incidence of neoplastic diseases at high doses has been observed by others[5]; a similar effect was found in the study of genetic mutation-rates[6]. It may be due to the lethal effect of radiation on tissue; a large dose may kill the cells, or may prevent the initial change in the cells, which would have later become manifest as a neoplastic condition.

The main conclusion from this work is that the shortening of life produced by radiation is due not to the induction of specific diseases but to the bringing forward in time of all causes of death, without any intrinsic change in their relative probabilities. From this point of view radiation may be considered as an ageing factor. It cannot, however, be identical with natural ageing, since the relative ages of onset of diseases are not the same in the irradiated as in the control populations.

NEW FINDS AT OLDUVAI GORGE

By Dr. L. S. B. LEAKEY

The Coryndon Museum, Nairobi, Kenya

IN *Nature* of December 17, 1960, p. 1050, I reported the discovery of the bones of a hominid foot as well as some other specimens, in deposits of Bed I at Olduvai, but in a geological stratum lower than that which yielded the skull of *Zinjanthropus* in 1959.

The deposit at site *F.L.K.N.N.* I, which yielded the foot bones, the few hand bones, some tiny skull fragments, the two clavicles and the 'lissoir', has since then yielded the greater part of a hominid mandible (see Fig. 1) (found by my son, Jonathan Leakey, on November 2), as well as parts of two hominid parietals (see Fig. 2).

From the mandible, it is possible to estimate that the age at death of this individual was about twelve years. This is on the basis of present-day tooth eruption, since the second molars are in occlusal position but little worn, while there is no sign whatsoever of the eruption of the third molars. It is realized, of course, that in Lower Pleistocene times growth may have been more rapid, and that this jaw may perhaps represent an individual of less than twelve years.

The new mandible can be regarded, almost certainly, as belonging with the two parietals, the foot bones, some of the hand bones, and one of the clavicles. Since these remains represent a hominid which is stratigraphically earlier than *Zinjanthropus*, they are of considerable scientific interest.

Although detailed study has not yet been undertaken, the following facts may be placed on record:

(*a*) The overall dental pattern does not appear to be compatible with the type seen in *Zinjanthropus* or any other Australopithecine, and it seems possible that we are dealing with a quite distinct type of early hominid.

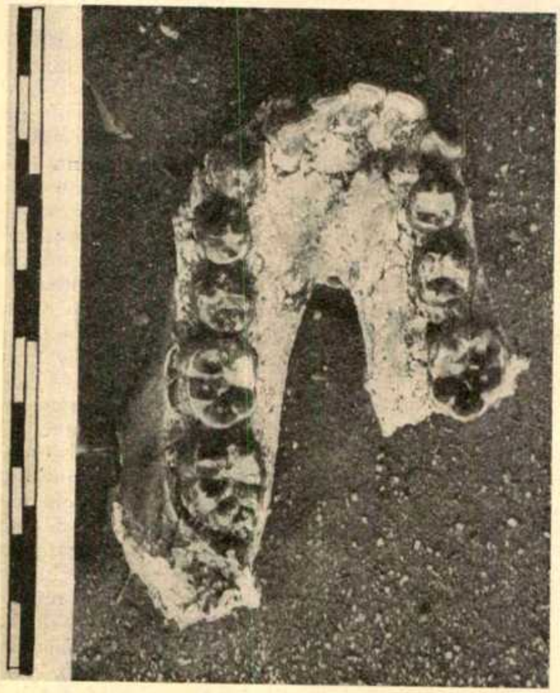

Fig. 1. The new jaw from site *F.L.K.N.N.* I Olduvai

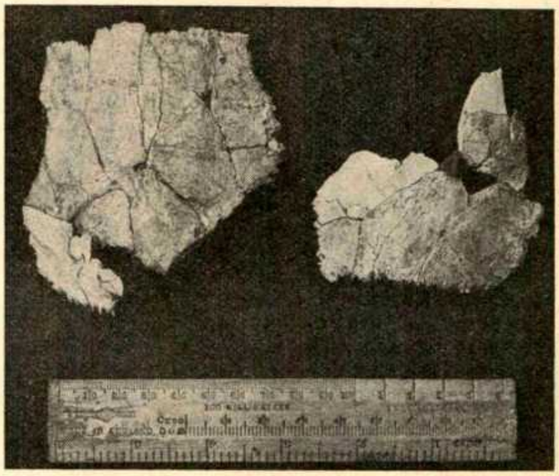

Fig. 2. Two frontals of a juvenile. They are a little larger than those of *Zinjanthropus*, and probably belong with the mandible

(*b*) The lower canines, while relatively large, are wholly hominid in type and morphologically quite unlike the canines of pongids, but recall *Australopithecus*.

(*c*) The lower incisors are also hominid in their general morphology although they do, to some extent, recall the lower incisors of *Proconsul*.

(*d*) The premolars are remarkable and are unlike what is normally to be seen in the Australopithecinæ. The anterior–posterior length in both the third and fourth premolars is greater than the bucco–lingual width, while the fourth premolar has very well-marked cuspules bordering the edge of a large posterior fovea.

(*e*) The first molar is well worn and has a general cusp pattern reminiscent of what can be seen in some recent Australian Aborigines, but it is of course larger.

(*f*) The second molar is much longer than the first and is remarkably elongate.

The mandible was unfortunately broken prior to fossilization, and part of the right ramus has been distorted and made to appear much nearer to the left half than is really the case. The *corpus mandibulare* is very massive indeed. Unfortunately, the lower margin of the mandible is missing, so that it is not possible to say anything about the lower rim of the mandible or of the symphyseal region.

The two parietals are especially remarkable because, although they apparently belong to a young individual only twelve years old (or less), they are larger than those of *Zinjanthropus*. They are remarkably thin, and exhibit no sign of a sagittal crest or of any marked temporal line. The lack of both these may, perhaps, be due in part to the youthful age. Nevertheless, these parietals suggest that we are dealing with a hominid with a larger brain capacity, as well as somewhat less specialized, than *Zinjanthropus*.

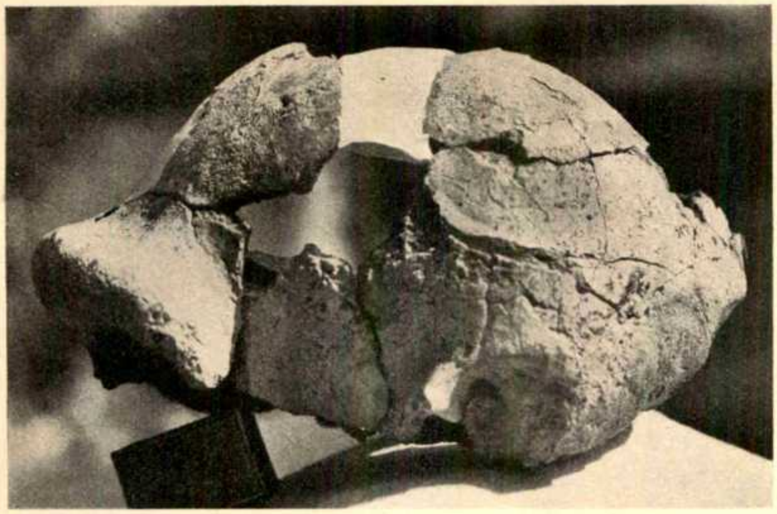

Fig. 3. Profile view of the skull of a man from Bed II Olduvai (*L.L.K.* II) found at a level which yielded abundant stone tools of Stage 3 of a Chellean culture. The skull is 209 mm. long

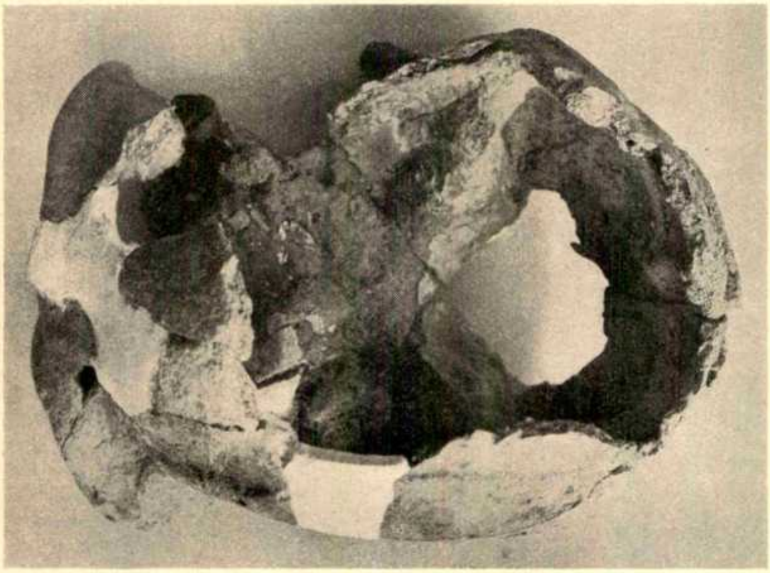

Fig. 4. View of the skull of Fig. 2 from above, to show the brow ridge area and other characters

At the time of writing the communication published in *Nature* of December 17, very few stone tools had been found in this lower level; since then, more have been found.

Another discovery of outstanding interest was made on December 2. This consists of the brain case (see Figs. 3 and 4) of a hominid from Bed II at Olduvai, at Site *L.L.K.* This skull was found at a stratigraphic horizon which yields quantities of stone tools of stage 3 of the Chellean culture. It may reasonably be assumed that we have, at last, found a skull representing the makers of the Chellean culture.

The Chellean culture was the first recognized stone-age culture ever to be officially accepted by science more than a century ago, but in all the years that have followed, no authentic find representing 'Chellean man' has been made other than two teeth found at Olduvai in 1954, and reported in *Nature* in 1958. In this connexion it must be noted here that *Atlanthropus*, found by Prof. Arambourg in North Africa, was, in the first instance, placed on record as being associated with Chellean tools; but this has since proved to be incorrect, since the cultural material found with them is quite clearly of Acheulean type.

This new skull from Olduvai, which comes from the well-established Chellean horizon in the gorge, is remarkable in a number of respects. It has a number of resemblances (although some of them are only superficial) to the Pithecanthropines. In other characters, however, the new skull shows considerable resemblances to the Steinheim skull from Germany, a specimen which is usually regarded as contemporary with the early phases of the Acheulean hand-axe culture and assigned to the genus *Homo*. The new skull also shows certain resemblances to two well-known African fossil skulls, those from Broken Hill and Saldhana, respectively. It is very large—209 mm. long and 150 mm. wide—and while the vault of the skull is low compared with present-day man, it is high compared with the fossil skulls from Java and Pekin. No discussion of points of detail will be attempted at present.

The third discovery made in recent months is that of an exceptionally rich living floor of a late stage of the Oldowan culture, some 20 ft. higher in Bed I than the *Zinjanthropus*-level and immediately underlying the 'marker bed' at the top of Bed I. The cultural material in this new floor is associated with a very rich fauna and is of special interest because it provides an intermediate stage between the ordinary Oldowan and stage 1 of the Chellean, as found at sites such as *B.K.* II. Moreover, the study of the fauna found here indicates that, at this level, man had more skill in hunting the large adult animals living at that time than is shown at the *Zinjanthropus*-level.

I wish to thank the National Geographic Society, which has enabled us to work in the field continuously since February 1960, with a large party. I also owe special thanks to my wife and to my son Jonathan, and to my senior assistant, Heselon, on whom the bulk of the work in this very long season has fallen. I am grateful to the Geological Survey of Tanganyika for making available the services of Dr. Pickering to carry out geological mapping on the sites, and on the Gorge as a whole. I also thank the many individuals, too numerous to name, as well as the Wenner Gren Foundation and the Wilkie Foundation, who have helped in a variety of ways to make this further season possible.

LETTERS TO THE EDITORS

ASTROPHYSICS

Oscillation Broadening of Lines from Ionized Elements in Stellar Spectra

THE well-known sources of line-broadening in stellar spectra may be summarized in two main groups. (1) Broadening resulting from the finite length of the wave-trains emitted by the atoms. The length is determined by (*a*) the finite life-time of the excited level, that is, radiation damping, and by (*b*) abrupt phase-changes in the emitted wave caused by perturbations of the emitting atoms by other particles, that is, collision damping and Stark effect. (2) Broadening resulting from Doppler effect of different types. The Doppler velocities may be of a random character, for example, thermal or turbulent motions of emitting atoms, resulting in a line profile of gaussian shape, or the broadening may result from the integration of contributions to the line from different parts of a rotating star, an expanding gas shell or a pulsating star. In addition, broadening or splitting of lines by magnetic fields (Zeeman effect) and by coupling between the nuclear spin and the angular momentum of the electrons of the emitting atom (hyperfine structure) can occur.

The aim of this communication is to direct attention to a broadening mechanism which has not been mentioned in the literature.

Abrupt disturbances introduced in a plasma will give rise to electron oscillations at, or near, the Langmuir frequency. To a first approximation, the electrons will perform harmonic, linear oscillations about a position of equilibrium, with a linear velocity $V_e = V_{oe} \cos \omega_p t$, where $\omega_p \sim$ Langmuir frequency, the restoring force being the field set up by the electrons themselves.

It will be shown in a subsequent paper (in preparation) that ions in the field set up by the electrons will oscillate with the same frequency as the electrons and with a maximum velocity:

$$V_{oi} = \frac{Z.2}{A.1{,}840} \cdot V_{oe}$$

where Z is charge of ion in units of electronic charge and A is mass of ion relative to the mass of the hydrogen atom.

This means, if the state of excitation of the oscillating ions is such that they give rise to an absorption or emission line, the observed line will, in addition to the width determined by the well-known sources mentioned above, show a broadening caused by Doppler velocities of the form $V = V_{oi} \sin \omega_p t$.

This broadening effect is proportional (1) to the oscillatory velocity of the electrons (or, to the magnitude of the oscillations) and (2) to the charge to mass ratio of the ions in question.

The line profile may be determined qualitatively by treating the phenomenon as a frequency modulated signal at a rest-frequency $\omega_o = 2\pi c/\lambda_o$ with a modulation frequency ω_p (the Langmuir frequency) and a modulation index $\beta = \dfrac{V_{oi}.\omega_o}{c.\omega_p}$, resulting in a line pattern consisting of frequency components centred at $\omega_o \pm n.\omega_p$, where $n = 0, 1, 2, 3. . . .$

The amplitude of the nth component is given by the Bessel function of the first kind and nth order with β as argument. In addition, each component of the line pattern is subject to conventional broadening.

Deflexion of Light in the Gravitational Field of the Sun

ACCORDING to the whirl theory of light and matter[1], the whole physical world is the manifestation of Maxwell's electromagnetic waves. The fundamental particles of matter, and the photons, are represented by integral solutions of Maxwell's equations *in vacuo*, in cylindrical co-ordinates. For the former the integral is taken from a very low limit of the variable parameter of the integrant solution to infinity, while in the latter the interval of integration is much smaller. The forces are determined from the standard equations of classical dynamics as the derivatives of the exchange integrals of electromagnetic fields of interacting entities with respect to parameters defining their mutual position. The necessary condition of physical validity of these forces is the synchronism between the fundamental frequencies of the entities or their sub-harmonics. In the case of gravitation the sub-harmonics are due to the 'micro-precessions' of the entities, of about $8 \cdot 3 \times 10^{-7}$ sec.$^{-1}$, caused by their inherent eccentricity of about 10^{-10} h/mc. In this very slow motion the wave-length of de Broglie's waves (which are inherent in these solutions of Maxwell's equations) is about 10^{12} cm. They are called the 'macrowaves'. The macrowaves produce the mutual synchronization of micro-precessions. The resultant macrowaves of thus synchronized particles constituting large axially symmetrical bodies, such as the Sun or the planets, form co-axially revolving wave systems with radial standing waves. The orbits of planets are situated in the troughs of the latter.

The whirl theory has permitted, so far, the calculation of fourteen physical constants from five observation data (c, h, e, the mass of the proton m_+, and the gravitational constant γ_g). These included the mass ratio of the proton and electron, the masses of the neutron and of the light nuclei ${}_1H^2$, ${}_1H^3$, ${}_2He^3$, and ${}_2He^4$, the distance from the Sun (ref. 1*k*), and the period of rotation and of sidereal motion, of Mercury, the relationship between the periods of rotation of planets and their distances from the Sun, and the magnetic moment of the Earth. The results of the calculations agreed very well with the observation data. The period of rotation of Venus (20 hr. 48 min.) which followed from these results appeared too small at that time (1950), but it was later confirmed by the radio-astronomical observations in the United States (22 hr. 16 min) disclosed in 1956 [2]. The whirl theory also permitted an explanation on the basis of Maxwell's electrodynamics of the growth of crystals from a grain of crystalline substance, the chemical catalysis, and the shifting to the red of spectral[1j] lines of remote nebulae.

Recently, I applied this theory to the calculation of the angle of deflexion φ of a light ray by the field of gravitation of the Sun, using the formulæ :

$$\varphi = \frac{\gamma_{pg} M}{c^2 D}\left[\left(\frac{D}{R}\right)^2 + 1\right]^{1/2} \cong \frac{\gamma_{pg} M}{c^2 R}$$

and
$$\gamma_{pg} = \left(\frac{q_p}{q_+}\right)^{1/2}\left(\frac{q_+}{q_-}\right)^{3/2}\gamma_g$$

where $q_p \equiv 2\pi/\lambda_p \quad q_+ \equiv 2\pi/\lambda_+ = m_+c/\hbar$

$$q_- \equiv 2\pi/\lambda_- = m_-c/\hbar$$

is the wave parameter of the photons in the deflected ray, of the proton, and of the electron, respectively ; m_+ and m_- are the mass of the proton and the electron, respectively ; c is the velocity of light, $\hbar = h/2\pi$ is the Planck constant ; M is the mass of the Sun, D is the distance of the Earth from the Sun, R is the nearest distance of the deflected ray from the centre of the Sun, γ_g is the gravitational constant between material masses, γ_{pg} is the gravitational constant between the material masses and the photon (the mass of the latter equals $\hbar q_p/c$).

The first formula has been derived from classical mechanics. The second formula can easily be deduced from formulæ (13·1) and (13·2) (ref. 1*j*). On substituting the numerical values, I obtain for the angle of deflexion $\varphi = 6{\cdot}2 \times 10^{-6}$ and $8{\cdot}75 \times 10^{-6}$ for the wave-length in the deflected ray 0·8μ (red light) and 0·4μ (violet light), respectively. The average (root mean square) between these two values is about $7{\cdot}8 \times 10^{-6}$.

Thus, according to the whirl theory, the angle of deflexion must depend upon the colour of the observed ray. This can only be verified by observation when the next opportunity (the solar eclipse) comes. It will be noticed that the average angle of deflexion calculated here is very near that obtained on the basis of Einstein's general theory of relativity. This may be due to the smallness of curvatures of geodesic lines assumed by Einstein in his calculations, thus bringing on this occasion the co-ordinate system of the general theory of relativity very near the co-ordinate system of the special theory of relativity which is implied in the whirl theory owing to the relativistic invariance of Maxwell's equations.

PHYSICS

Recombination through Electron–Electron Collisions

IN dense plasmas recombination through electron–electron collisions can be the major cause of loss of free electrons. The mechanism is akin to three-body ionic recombination but differs because of the long-range Coulomb forces involved, because the bound states cannot be treated as forming a continuum and because of the effect of radiative transitions.

Suppose that the ions are protons and suppose also that the temperature is such that the mean thermal energy is much less than the first excitation energy of hydrogen. Radiative recombination is slow but highly excited hydrogen atoms are rapidly formed through electron–electron collisions :

$$H^+ + e + e \rightarrow H' + e$$

These atoms may be ionized by the reverse process ; or they may gain or lose internal energy by suffering superelastic or inelastic collisions with electrons, or by absorbing or emitting photons. The passage of an electron from a state of the continuum to the ground state of an atom is clearly in the nature of a random walk during the course of which many different states may be entered.

Now the rates at which atoms in a particular excited state are produced or destroyed per unit volume by the collision and radiative processes mentioned are very much greater than the rate at which the minute number-density of atoms in that state changes. For given number-densities of free electrons and of normal atoms and given temperature it is hence possible to calculate the number densities of atoms in the various excited states by setting up and solving the matrix equation expressing the close equality of the production and destruction rates. It is then a simple task to calculate the rate at which the number-density of normal atoms is increasing. Since the number-density of excited atoms is, relatively, very small, this rate may be taken to be the rate of disappearance of free electrons. The recombination coefficient, $\alpha(n)$, defined by the equation :

$$\frac{dn}{dt} = -\alpha(n)n^2$$

in which n is the number-density of free electrons, may hence be found.

Calculations have been carried out to cover various conditions. Details will be published elsewhere. Some representative results are presented in Fig. 1. This refers to a plasma at a temperature of 16,000° K. which is almost completely ionized and which is optically thin so that the absorption of the emitted photons may be neglected. If n is less than about 10^{11}/cm.^{3}, $\alpha(n)$ is only about 3×10^{-13} cm.^{3}/sec., which is the value corresponding to radiative recombination. However, if n is greater than 10^{14}/cm.^{3}, recombination through electron–electron collisions is dominant and $\alpha(n)$ is very much larger ; indeed, as n tends to infinity $\alpha(n)$ tends to $9 \times 10^{-28}n$ cm.^{3}/sec. The peculiar slight change in the slope of the graph when n is between 10^{15}/cm.^{3} and 10^{16}/cm.^{3} arises because the ratio of the actual to the Saha-equilibrium population in the second quantum-level becomes comparable with its limiting value, unity, here ; and consequently, the rate at which this ratio increases as n increases ceases being rapid and becomes slow. It may be remarked that while collisions with electrons control the rate of degradation of excited atoms in the high-density limit, bound–bound radiative transitions are generally extremely important.

Several experimental studies[1] have been made on the decay of pulsed condenser and other discharges in which n was about 10^{16} to 10^{17}/cm.^{3}. Values of $\alpha(n)$ of about 10^{-13} cm.^{3}/sec.–10^{-11} cm.^{3}/sec. have been

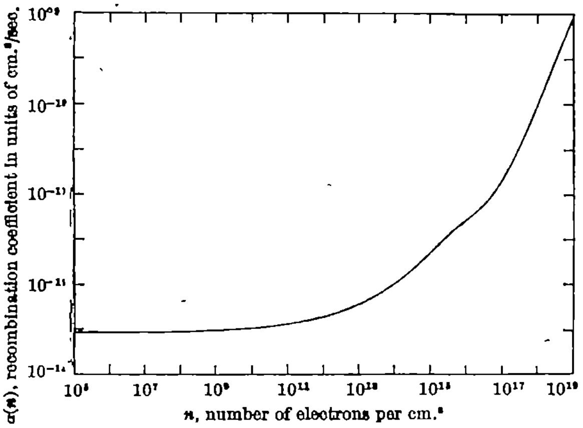

Fig. 1

deduced. Some of these values are far less than would be expected from the theory outlined here. However, the experimental studies concerned give no information on the recombination coefficient. This is so great that the number-density of free electrons simply followed the changing equilibrium as the discharge cooled.

A New Type of Phenomenon of Flow Birefringence in Macromolecular Solutions

During an investigation of solution states of methyl cellulose in aqueous systems, an unexpected new phenomenon was noted. The observed optical anisotropy as a function of the velocity gradient in the systems changed anomalously, as shown in Fig. 1 (solid lines). Reproducibility of the variations both of the degree of birefringence and the angle of extinction versus the rates of shear were within experimental error.

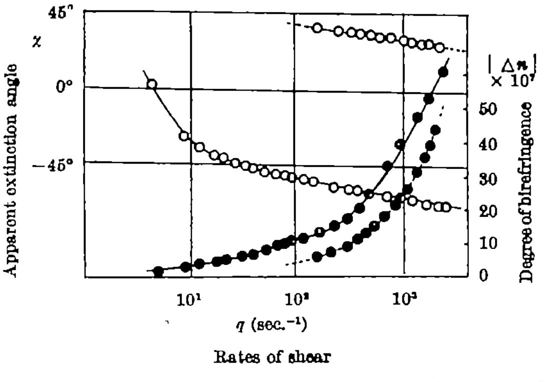

Fig. 1. Variations of the optical anisotropy and the degree of birefringence vs. the rates of shear: original methyl cellulose/water solution (dotted lines); aged methyl cellulose/water solution (solid lines).—○—, optical anisotropy (χ); —●—, birefringence (Δn)

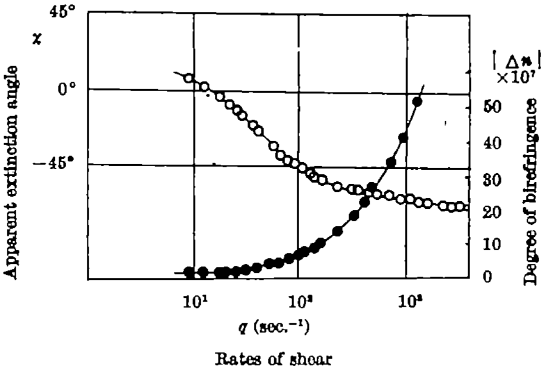

Fig. 2. Variations of the optical anisotropy and the degree of birefringence vs. the rates of shear in a methyl cellulose/methyl alcohol/water system

Dilute aqueous solutions of 'Methocel' (Dow Chemical's powdered methyl cellulose: U.S.P. grade, *MC*-4,000 c.p., average molecular weight determined by viscometry about 140,000) were used in this investigation.

The dotted lines in Fig. 1 represent the normal flow birefringence obtained in the fresh solution, for comparison with the new phenomenon observed after the solution has been aged for two or more months at room temperature (about 30° C.).

A similar marked anomaly was noted in aged aqueous solutions even in fresh aqueous solution of methyl cellulose containing 50 volume per cent of methyl alcohol (see Fig. 2). With a mixed system of ethyl alcohol and water, an effect similar to that with methyl alcohol/water was noted.

It is difficult to find a theoretical explanation of the phenomenon. It seems to be connected with the fact that the solution states of aqueous methyl cellulose are not stable, in spite of the non-ionic nature of the polymer structure. The association of the chain molecules proceeds mainly due to dehydration of the molecules after the solution has been aged[1,2].

Further additional information has been obtained about this effect, using a solution which was mixed with considerable quantities of methyl alcohol in order to regulate the solvent power or the degree of dehydration of the polymer chains. The polymer concentration of the solutions was 1 per cent throughout the investigation, and no essential difference was found between the results obtained in the aged solutions and in the mixed systems. Both effects can probably be attributed to inter- and intramolecular hydrogen bonds between exposed hydroxyl groups of the polymer chains suffering dehydration during ageing, or artificially by the addition of a strong hydrophilic substance such as the alcohol.

The anomalous variations of the extinction angle with increasing rates of shear are still unexplained, and work is in progress to shed more light on the problem.

The Relativistic Theory of the Fresnel Drag Coefficient

In this communication I give a somewhat more general discussion of the Fresnel drag coefficient than is usual, with the view of clarifying the relation between two expressions for it, which occur in the literature of special relativity. These expressions are normally derived separately and their relationship has recently been discussed by Synge[1]. I take a further step here, by showing how both results can be obtained from a single argument. This procedure directs appropriate attention to step (6) (see below), which is the crucial point in both cases. The necessary background may be outlined as follows:

Suppose a medium has velocity v parallel to the x-axis of a reference system S. If light passes through the medium parallel to this direction, let its phase velocity be u_m relative to S. Assume that $u_m = c/n(\nu_m)$, where $n(\nu_m)$ is the refractive index of light of frequency ν_m in the medium, provided the medium is at rest in S (that is, $v = 0$). Then in the general case ($v \neq 0$):

$$u_m = c/n(\nu_m) + kv \qquad (1)$$

Here k is a coefficient which was once supposed to measure the extent to which the æther is dragged along by the medium (Fresnel, 1818). The special relativity theory also leads to (1). For k, it yields the result:

$$k = 1 - \frac{1}{n(\nu_0)^2} + \frac{c}{v}\,\frac{\nu_0}{n(\nu_0)^r}\left\{\frac{\mathrm{d}n(\nu)}{\mathrm{d}\nu}\right\}_{\nu = \nu_0} \qquad (2)$$

Here $r = 1$ in the case of water flowing at velocity v in a tube fixed in S, and $r = 2$ for a block of glass moving with velocity v. These are the two cases usually described.

Consider now a uniform transparent medium in uniform motion with velocity v parallel to the x-axis of an inertial system S. The medium is contained in a transparent vessel the walls of which can unfold during the motion of the medium, so that the rear face of the container (which is perpendicular to the x-axis) moves with a velocity $w \leqslant v$. The optical properties of the medium in the container are, however, kept homogeneous and constant in time by feeding additional material through a tube leading to the rear of the container. This means that we assume the following idealized situation: At any time t, contact between the rear surface of the container and the medium is about to break due to the difference in velocity. But the gap $(v - w)\mathrm{d}t$, which one would expect to develop in time $\mathrm{d}t$, is filled in by additional material having already v as its x-component of velocity. Contact between the rear surface and the medium is assumed to be maintained in this way; different layers of material are involved in the contact at different instants. This situation cannot be realized exactly, but my main interest is in the two limiting cases, which can be realized.

Let the reference system in which the medium is at rest be S'; that in which the rear face is at rest, be S''; the velocity of S'' as observed in S' be w'; the frequency of the light when moving in vacuum and observed in S'' be ν_0'' and the frequency when moving in the medium and observed in S'' be ν_m''. I shall adopt this type of notation also for the frames S and S' and for the phase velocity of the light, which is denoted by u_0 for vacuum and by u_m for the medium.

By the relativistic velocity addition:

$$u_m = \frac{u_m' + v}{1 + u_m' v/c^2} = \frac{c/n(\nu_m') + v}{1 + v/cn(\nu_m')} \qquad (3)$$

It has been assumed that $u_m' = c/n(\nu_m')$, where $n(\nu_m')$ is the refractive index of the medium for waves of frequency ν_m'. Suppose now that if g is a function of order v/c, we have, to first order in v/c:

$$\nu_m' = \nu_0(1-g) \qquad (4)$$

It then follows that:

$$\frac{1}{n(\nu_m')} = \frac{1}{n(\nu_0-\nu_0 g)} = \frac{1}{n(\nu_0)} - g\nu_0\left\{\frac{\mathrm{d}}{\mathrm{d}\nu}\left[\frac{1}{n(\nu)}\right]\right\}_{\nu = \nu_0}$$

$$= \frac{1}{n(\nu_0)} + \frac{g\nu_0}{n(\nu_0)^2}\left\{\frac{\mathrm{d}n(\nu)}{\mathrm{d}\nu}\right\}_{\nu = \nu_0}$$

Substituting in (3), one finds, to first order:

$$u_m = \frac{c}{n(\nu_0)} + kv$$

$$\text{where } k \equiv 1 - \frac{1}{n(\nu_0)^2} + \frac{c}{v}\,\frac{\nu_0}{n(\nu_0)^2}\,g\left\{\frac{\mathrm{d}n(\nu)}{\mathrm{d}\nu}\right\}_{\nu = \nu_0} \qquad (5)$$

Here k has the form of a Fresnel drag coefficient. It remains to calculate g.

From the expressions for the radial Doppler effect:

$$\frac{\nu_m''}{\nu_m'} = \frac{\sqrt{(1-[w']^2/c^2)}}{1 + w'/u_m''},\quad \frac{\nu_0''}{\nu_0} = \frac{\sqrt{(1-w^2/c^2)}}{1 + w/u_0''}$$

Now the rear wall of the container is at rest in S'' so that the light entering it is unchanged in frequency for an observer at rest in S'':

$$\nu_0'' = \nu_m'' \qquad (6)$$

Hence to first order in v/c:

$$\frac{\nu_m'}{\nu_0} = \frac{\nu_0''/\nu_0}{\nu_m''/\nu_m'} = 1 + \frac{w'}{u_m''} - \frac{w}{u_0''}$$

The last two terms are correction terms and need be evaluated only to zero order, so that:

$$w' \doteqdot w - v,\quad u_m'' = c/n(\nu_0'') \doteqdot c/n(\nu_0)$$

Noting that $u_0'' = c$, one finds that equation (4) is valid, provided:

$$g = \frac{w + (v - w)n(\nu_0)}{c} \qquad (7)$$

Combination of (5) and (7) yields an expression for the drag coefficient. One notes that $w = 0$ corresponds to the case of water flowing through a tube, while $w = v$ corresponds to the moving block of glass in accordance with (2). One can say qualitatively: The effect of dispersion on the drag coefficient goes up with the disparity between the velocity of the medium and the velocity of the rear face of its container.

RADIATION CHEMISTRY

Photolysis of Ethyl Iodide Solutions

ONE of the major products in alkyl iodide photolysis in various solvents is iodine, formed by combination of iodine atoms produced in the primary dissociation. Although the reaction is well known, quantum yields reported for iodine vary from zero to one[1-6]. In part, the scatter in the data from different laboratories is caused by the presence of undetermined amounts of oxygen. Hacobian and Iredale[6] pointed out the difficulty of complete removal of oxygen from these solutions in organic solvents, and found that the iodine yield decreased from 0·5 to less than 0·05 as the solution was degassed. Earlier work[1,5] indicated a decrease of about a factor of two in iodine-yield on removal of oxygen.

The present research started with the premise that complete removal of oxygen from a hydrocarbon solvent is best accomplished by chemical reaction. Alkaline pyrogallol solutions were equilibrated with the solute, ethyl iodide, and the solvent, *n*-hexane. After separation of the layers, each component was subjected to exhaustive vacuum distillation and outgassing. The reagents could then be distilled from storage into a 1-cm. path-length silica vessel and sealed off. Photolyses were carried out in the full arc of a 250-watt B.T.H. mercury arc lamp, which gave a weighted mean absorbed wave-length of about 3100 Å. Absorbed intensities during photolysis were obtained by ferrioxalate actinometry[7]. The concentration of iodine produced was measured directly in the reaction cell at 5250 Å.

In the absence of oxygen, the initial iodine quantum yield was 0·017, which agrees qualitatively with the value of < 0·05 found by Hacobian and Iredale. However, it was observed that as iodine accumulated in the solution the quantum yield decreased considerably. The effect can be interpreted on the basis of the reaction[8] :

$$C_2H_5 + I_2 = C_2H_5I + I \qquad (1)$$

As iodine accumulates in the system, reaction (1) increases in importance compared with the dimerization and disproportionation of ethyl radicals. In the limit of high-conversions, iodine reaches a steady-state concentration and the quantum yield of iodine formation approaches zero.

After equilibration with air the initial iodine quantum yield was higher by a factor of two than that in the complete absence of oxygen. It is recognized that oxygen effects the removal of ethyl radicals from the system, or, at least, prevents them from reacting with iodine atoms. Thus the quantum yield is generally higher in the presence of oxygen than in its absence because secondary recombination is largely prevented. The probable mechanism can be represented by the following secondary reactions, following dissociation into ethyl radicals and iodine atoms :

$$2C_2H_5 = C_4H_{10} \text{ or } C_2H_4 + C_2H_6 \qquad (2)$$

$$C_2H_5 + I = C_2H_5I \qquad (3)$$

$$2I = I_2 \qquad (4)$$

$$C_2H_5 + O_2 = \text{products} \qquad (5)$$

(It must be kept in mind, however, that only the rate formation of iodine molecules was followed in the work described.) In the absence of oxygen, reactions 2, 3, and 4 are the reactions involved in the formation of iodine, while in the presence of oxygen 4 and 5 are the only reactions taking part. Then it can be shown that the ratio of iodine quantum yield with oxygen present to that with oxygen absent is given by :

$$R = 1 + k_3/2(k_2k_4)^{1/2}$$

If the values of the rate constants k_2, k_3 and k_4 in solution are determined by statistics, that is, $k_2 = k_4 = \frac{1}{2}k_3$, R would have the value 2, in agreement with our experiments. Hacobian and Iredale found experimentally a value of R in excess of 10, which would require $k_3^2 > 300k_2k_4$. However, there is no reason to suspect reactions 2 and 4 to be so inefficient in solution compared with reaction 3.

This ratio of rate constants, based on the same mechanism, gives for the initial iodine quantum yield in the absence of oxygen :

$$\Phi_{I_2} = \frac{\varphi}{2 + k_3/(k_2k_4)^{1/2}}$$

where φ represents the quantum yield of dissociation into fragments free of the solvent cage. The value of φ determined by these experiments is 0·07. However, the possible presence of a scavenger capable of reaction with iodine atoms was not eliminated. Although this would not affect qualitatively the conclusions regarding the decrease of Φ_{I_2} with increasing conversion or its increase in the presence of oxygen, the absolute value of Φ_{I_2} could be in error. For this reason, aside from the technique of rigorous purification of solvent employed by Lampe and Noyes[8], it would be most desirable to remove oxygen with an inorganic reducing agent to avoid all possibility of introducing impurities which may act as inhibitors.

Tritium as a Source of Radiation in Electron Spin Resonance Studies

A COMMON difficulty encountered in electron spin resonance investigations of materials irradiated by high-energy radiations (cobalt-60 γ-rays, fast electrons, etc.) is the appearance of the electron spin resonance spectrum of the irradiated glass (or quartz) tubes containing the samples.

The spectrum often becomes interpretable only after either 'bleaching' the glass or transferring the sample to a non-irradiated tube. Both procedures may be particularly awkward in experiments involving stabilization of free radicals at low temperatures.

It was expected that the above difficulties might be avoided by using internally emitted tritium β-particles, which, owing to their very low energies (< 18 keV.) and ranges (about 1μ in glass and most solid media), should leave the glass of the sample tube practically unaffected even for relatively high doses of radiation absorbed in the sample.

In order to test this conception, solutions of tritium oxide in water, deuterium oxide and water + deuterium oxide mixtures with activities 100 mc./ml. and 1 c./ml. were frozen down in glass tubes in liquid nitrogen. The electron spin resonance spectra of the samples irradiated in this way were then examined at liquid-nitrogen temperature.

After applying doses of radiation up to 5×10^{20} eV./ml., no effects of the irradiated glass on electron spin resonance spectra were observed.

The spectra of tritium β-irradiated water and deuterium oxide ice consist of one doublet and one triplet, respectively, and are interpreted as due to OH and OD radicals.

The corresponding g values, separation and line-widths are almost identical with those reported for cobalt-60 γ-irradiated ice[1]. The yields of OH and OD formation [(G(OH), G(OD)], and the saturation concentrations of both radicals seem to be lower than for γ-rays. This difference may be due to the higher linear energy-transfer of tritium β-particles.

In the presence of perchloric acid in tritiated water and deuterium oxide ice, hydrogen atoms and deuterium atoms are readily formed as in the experiments by Livingston and Weinberger[2], using cobalt-60 γ-rays.

The spectrum of a tritiated mixture of water, deuterium oxide and perchloric acid indicates the presence of all the radicals concerned, that is, H, OH, D and OD, and enables one to compare directly their rates of formation and stabilities.

Full details and further discussion of these experiments will be published elsewhere.

CHEMISTRY

Nature of the Metallic Orbital

IN the course of the development of the resonating-valence-bond theory of metals[1] it became evident[2] that the characteristic structural feature of metals is the possession by each of many atoms in the metal of an extra orbital (the metallic orbital) in addition to the orbitals normally occupied by electrons. This metallic orbital permits the unsynchronized resonance of covalent bonds from one interatomic position to another by the jump of an electron from one atom to an adjacent atom without the need for an opposite jump to retain exact electric neutrality. The metal can thus be described as containing atoms with formal charges + 1 and − 1 as well as zero (larger formal charges are ruled out by the electroneutrality principle[3]).

A puzzling feature of the theory has been the fractional number, 0·72, of metallic orbitals per atom that is found by analysis of the values of the saturation ferromagnetic moments of the metals of the iron group and their alloys[2]. A simple derivation of an approximate value of this number, reported here, has now been discovered.

Let us consider[4] a metal such as lithium, with one valence electron per atom. The bonds occupy principally the positions between each atom and its eight nearest neighbours in the body-centred cubic crystal. The probability of a bond in a position is 1/8, and the probability of a vacancy is 7/8; it is easily seen that the relative probabilities of Li^+, Li and Li^- (with 0, 1 and 2 bonds, respectively) are in the ratios 7 : 8 : 4, or, with Li^+ and Li^- made equal by taking the geometric mean, 0·285 : 0·430 : 0·285. For other metals similar calculations give ratios lying between this limit and 1/3 : 1/3 : 1/3.

Atoms M^+ and M need to have a metallic orbital in order to be able to accept an additional bond; M^-, however, does not need a metallic orbital, because it is prevented by the unfavourable energy term of M^- from accepting another bond. Hence the number of metallic orbitals per atom is expected to be the sum of the probabilities of M^+ and M. This sum, as given by the above calculation, lies between 0·715 and 0·67. The experimental value, 0·72, is close to one end of this range; it corresponds with 28 per cent M^+ and M^-. It is, of course, likely that the probabilities of M^+ and M^- relative to M are decreased somewhat by the energy of separation of charge.

As an example, we may consider white tin, for which the observed interatomic distances indicate the valence to be about 2·64. There are four outer orbitals ($5s5p^3$), and Sn^+, Sn and Sn^- have 3, 4 and 5 outer electrons, respectively. The first two must have a metallic orbital; hence their valencies are 3 for Sn^+ (spp), 2 for Sn (s^2pp) and 3 for Sn^- (s^2ppp), with weighted average 2·56, in agreement with the value given by the interatomic distances.

Nature of the Reactions involved in the Pyrolysis of *n*-Butane inhibited by Propylene

IN order to explain the observed features of the pyrolysis of paraffin hydrocarbons in the presence of such rate-inhibitors as nitric oxide, propylene and *iso*butene, it has been suggested[1] that the uninhibited reaction consists of two independent, concurrent mechanisms. The first is assumed to be an unbranched free-radical chain process, the second, a molecular elimination process. It is assumed[1] that the former can be entirely suppressed by the addition of sufficient inhibitor. In the pyrolysis of *n*-butane, for example, the reactions responsible for the production of the major products through the free-radical mechanism are most likely to be :

$$C_4H_9^{\cdot} \longrightarrow CH_3^{\cdot} + C_3H_6 \qquad (1)$$

$$C_4H_9^{\cdot} \longrightarrow C_2H_5^{\cdot} + C_2H_4 \qquad (2)$$

$$CH_3^{\cdot} + C_4H_{10} \longrightarrow CH_4 + C_4H_9^{\cdot} \qquad (3)$$

$$C_2H_5^{\cdot} + C_4H_{10} \longrightarrow C_2H_6 + C_4H_9^{\cdot} \qquad (4)$$

and, in the supposedly molecular portion of the reaction :

$$C_4H_{10} \longrightarrow CH_4 + C_3H_6 \qquad (I)$$

$$C_4H_{10} \longrightarrow C_2H_6 + C_2H_4 \qquad (II)$$

Both mechanisms predict equal yields of ethylene and ethane.

Alternative interpretations of the experimental evidence[2,3] discount the possibility of the participation of molecular processes and attribute the completely suppressed reaction to some form of modified radical chain.

We have used the technique of high-speed gas-liquid chromatography[4] in conjunction with a high-sensitivity flame-ionization detector to study both the uninhibited pyrolysis of *n*-butane and the reaction in the presence of varying amounts of propylene. The identity of the products was unchanged under all conditions, and the distribution of the major products, as reflected in the ratio [methane/(ethane + ethylene)], was virtually independent of the pressure of propylene. In the uninhibited reaction the ratio C_2H_4/C_2H_6 ($= \alpha$) was found to be consistently greater than unity, being commonly approximately 2, while values as large as 4 have been obtained.

Some results obtained in the investigation of the pyrolysis at 778·7° K., under a pressure of 19·2 mm. mercury, of *n*-butane in the presence of various pressures of propylene are summarized in Fig. 1. It is seen that the overall rate of reaction is reduced by a factor of about three on increasing the pressure of propylene to 6 mm. The value of α, however, increases linearly through this region, and beyond, rising from 1·9 to 2·5 as the pressure of propylene changes from 0 to 30 mm.

If now it is assumed that the fully suppressed reaction [$C_3H_6 > 6$ mm.] is completely molecular in character, it follows that the intercept on the ordinate of the plot of α against pressure of propylene represents the value of α pertaining to any molecular processes occurring in the uninhibited reaction. This value is found to be identical with that determined in the experiment carried out in the absence of propylene. This identity is of considerable importance since it requires that, if the residual reaction is entirely molecular, either (*a*) the uninhibited reaction is entirely molecular, or (*b*) if radical and molecular processes occur concurrently in the uninhibited reaction, then :

$$\alpha_{\text{observed}} = \alpha_{\text{radical}} = \alpha_{\text{molecular}} \qquad (A)$$

The possibility that (*a*) is true can be immediately discounted.

Since results similar to those shown in and deduced from Fig. 1 were obtained in all the experiments conducted over the usual ranges of temperature and initial pressure of *n*-butane, it is evident that, if (*b*) is true, relation (*A*) must hold in all such conditions. That is, whatever mechanisms give rise to $\alpha > 1$, both radical and molecular, must have identical kinetic characteristics.

The characteristics associated with the formation of this 'excess ethylene' [$= C_2H_4 - C_2H_6$] in the uninhibited reaction are :

(i) α remains constant throughout at least the initial 5 per cent of any given reaction.

(ii) The excess of ethylene is formed at the expense of the ethane, since the C_2 hydrocarbons form a constant proportion of the product at any given temperature.

(iii) The variation with temperature of the function :

$$\alpha - 1 = \frac{[C_2H_4] - [C_2H_6]}{[C_2H_6]}$$

at any given pressure of *n*-butane is associated with an activation energy of (28·6 ± 2·5) k.cal./mole.

(iv) The total order of the reaction forming the excess of ethylene is less than that of the reaction forming the ethane, and varies with total pressure.

The inclusion of the reaction :

$$C_2H_5^{\bullet} \longrightarrow C_2H_4 + H^{\bullet} \qquad (5)$$

in the free-radical mechanism adequately accounts for the findings summarized in (i) to (iv). On the other hand, while several molecular reactions which could give rise to $\alpha > 1$ can be postulated, it seems impossible to envisage any counterpart of reaction (5) which, in combination with (I) and (II), would be compatible with relation (*A*) and the restrictions imposed by (i)–(iv). Thus, possibility (*b*) must be eliminated.

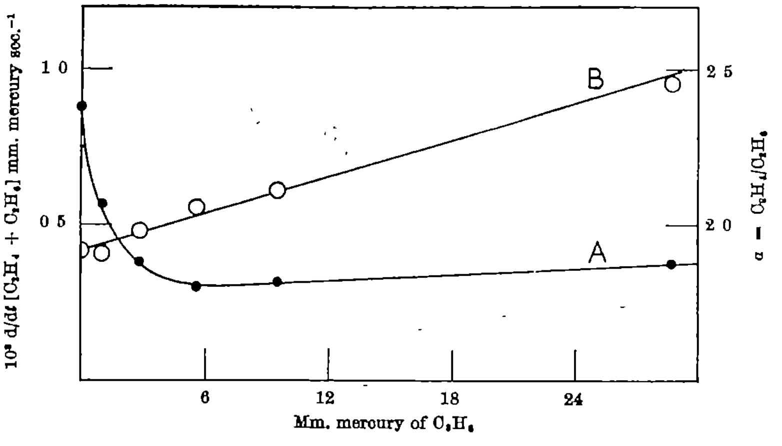

Fig. 1. Effect of the addition of propylene on the pyrolysis of 19·2 mm. mercury of *n*-butane at 778·7° K. Plots show the dependence on pressure of propylene of (*A*) the initial rate of formation of the total C_2 fraction and (*B*) the ratio $\alpha = C_2H_4/C_2H_6$

Since, therefore, molecular processes appear to play no part in the completely inhibited reaction, it is evident that both the uninhibited and inhibited reactions must be regarded as entirely free-radical in character. This conclusion is in harmony with the experimental findings which, for the completely suppressed reaction, are then best described in terms of a modified free-radical chain reaction propagated by radicals of low reactivity[3].

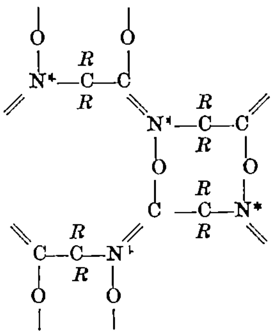
Possibility of Ionic Dissociation at the Peptide Linkage

THE need for a cyclic structure for certain proteins (for example, serum globulins) has been emphasized in a series of papers by Wrinch[1,2]. However, the hexacyclic carbon–nitrogen ring structure which she proposes has not been generally accepted, due partly to steric objections. It is believed at present that two-dimensional protein structures are formed by hydrogen bonding between polypeptide chains. In the present communication a new oxygen cross-bonded structure is suggested. It is characterized by ionic dissociation, and a double bond, at the peptide linkage. The structure is:



where N* is either N^- or $(HNH)^+$ depending on whether the dissociation:

$$NH \rightarrow N^- + H^+ \qquad \text{(acidic)}$$

or

$$NH + H^+ \rightarrow NH_2^+ \qquad \text{(basic)}$$

occurs. The amino-acid residues (*R* groups) and the H ions of $(HNH)^+$ groups lie perpendicularly to the plane of the structure.

The reason why both acidic and basic dissociations are thought to be possible is as follows. In the above structure, N atoms complete their $n = 2$ shell octet by sharing 4 of their 5 valence electrons in covalent bonds with neighbouring atoms. The fifth valence electron is therefore forced up into a 3*s* level where it will behave very much like the 3*s* valence electron of sodium. One knows that sodium hydride dissociates into Na^+ and H^- ions (the latter combining with H^+ ions of water to give H_2) and consequently one might expect that NH would dissociate similarly. This is essentially the basic dissociation shown above. However, the 3*s* electron of the N will be more tightly bound than the 3*s* electron of Na when the adjacent amino-acid residues are electrophilic (electron deficient), because then the covalent bonds to the N atom will tend to be polar, causing the N charge to exceed by a slight amount one electron charge. In this case acidic dissociation of NH may be expected. The dependence of the type of dissociation on the electrophilic or nucleophilic character of adjacent amino-acid residues means that the genetical code of a protein residing in its sequence of amino-acids can be transferred to a sequence of ionic charges at the peptide linkages.

The delicate balance between acidic and basic dissociation at the peptide linkage will mean that the free energy of dissociation is exceptionally small. One therefore expects proteins to be precipitated by slight changes to the solvent. It is well known that slight changes of *p*H and reagents such as methanol do, unaccountably, precipitate protein. One may expect also a tendency of positively charged ions of the correct electronegativity to complex with N^- ions at the peptide linkage. This may explain the denaturation of proteins by heavy ions in solution, and possibly also the different response of biological organisms to the chemically similar Na^+ and K^+ ions and the chemically similar Ca^{2+} and Mg^{2+} ions.

A definite need to invoke new dissociations has been found in the case of the proteins of tobacco mosaic virus[3] and in the case of silk fibroins[4]. The net charge of these proteins indicated by electrophoretic measurements differs considerably from that deduced from chemical analysis (for the same *p*H). Furthermore the *p*H of minimum movement under an electric field (the true isoelectric point by definition) differs from the *p*H of minimum combination with acid or alkali (often termed the isoionic point).

Preliminary experiments I have made show that ultra-violet irradiation can alter the net charge of serum protein. Part of a protein front moving along an electrophoretic strip in a buffer of *p*H 8·6 was made to pass through a narrow band of ultra-violet radiation. In the case of negatively charged protein (albumins) the ultra-violet irradiation produced an acceleration, while in the case of positively charged protein (γ-globulins) a retardation was noted. It would seem that the ultra-violet irradiation tended to increase the net negative charge of the protein by destroying positive charges. Since it is reasonable to assume that the ultra-violet irradiation is absorbed at a double bond, this appears to constitute evidence for ionic dissociation at the peptide linkage.

BIOCHEMISTRY

Induced Protein Synthesis

A POSSIBLE relationship between the synthesis of induced enzymes and the formation of antibodies was suggested in 1900 by Dienert[1]. Compelling arguments[2] have since accumulated to support this contention, but corroborative experimental evidence has not been forthcoming until recently. This laboratory has been engaged in obtaining such evidence by an investigation of the specificities of antibodies and enzymes induced by the same determinant group.

Known inducers for specific enzyme systems were coupled to bovine serum albumin with the determinants held in covalent linkage putative to the bond which might exist in comparable inducer-macromolecular complexes in microbial systems. The specificities of rabbit antibodies to these conjugated proteins were studied by hapten-inhibition techniques, on the premise that a similarity in the mode of formation of antibodies and induced enzymes might be reflected in analogous conformational and stereochemical requirements at their respective combining sites. The antibody specificities determined in this manner were then compared with previously reported specificities for the haptens acting as inducers or substrates for the corresponding induced enzyme systems. A good correlation was observed between the specificity of rabbit antibodies to protocatechuoyl-bovine serum albumin and the induction of protocatechuic acid oxidase in *Neurospora*[3]; between the specificity of antibody to β-D-galactosido-phenylazo-bovine serum albumin and the β-D-galactosidase enzyme system of *E. coli* and *B. megaterium*[3,4]; and between the inducible β-D-glucosidase of *Rhodotorula minute*, the constitutive β-D-glucosidase from *Stachybotrys atra*, and antibodies formed in response to β-D-glucosido-phenylazo-bovine serum albumin[5]. The results also suggested[3] that the inducible mechanism (permease)[6] for the transport of β-D-galactosides into *E. coli* may follow the specificity requirements of other β-D-galactoside accommodating systems.

The similarity between the specificities of antibodies to β-D-galactosido-phenylazo-bovine serum albumin and the corresponding inducible enzyme in *E. coli* was further demonstrated experimentally, as shown in Table 1. The results of a typical series of experiments employing a 1 : 5 : 16 ratio (based on nitrogen) of enzyme, antigen, and antibody are presented. Incubation of the synthetic conjugated antigen β-D-galactosido-phenylazo (Gal)-bovine serum albumin with an enzyme extract from *E. coli*, prior to addition of antibody, inhibited hydrolysis of the chromogenic substrate, *o*-nitrophenyl-β-D-galactoside. In other experiments the concentration of antigen was reduced tenfold, with other concentrations held equal, and pre-incubation of Gal-bovine serum albumin with enzyme still completely inhibited hydrolysis of *o*-nitrophenyl-β-D-galactoside. Galactosyl groups were not hydrolysed from Gal-bovine serum albumin by β-D-galactosidase. This indicates that the binding sites of the enzyme were specifically occupied, while the catalytic site may have been sterically hindered by the bulk of the conjugated antigen. Simultaneous addition of the antibody to enzyme and Gal-bovine serum albumin did not affect enzyme action. It appears, therefore, that the binding sites of the enzyme and the antibody can compete for the specific polyvalent non-substrate. The enzyme-Gal-bovine serum albumin complex, once formed, was not dissociated by antibody. With simultaneous additions, the antibody reacted with antigen more rapidly, and possibly more firmly, than did the enzyme. It might be possible to reverse inhibition of hydrolysis of *o*-nitrophenyl-β-D-galactoside by enzyme with Gal-bovine serum albumin provided that sufficiently high concentrations of substrate are added. It will be of interest to study the kinetics of competition of enzyme and antibody for antigen. It should also be noted that antibody had no catalytic effect on hydrolysis of substrate, although hapten-inhibition tests[4] demonstrated strong specific binding of this substrate at the antibody combining site.

Table 1. COMPETITION BETWEEN *E. coli* β-D-GALACTOSIDASE AND RABBIT ANTI-β-D-GALACTOSIDO-ANTIBODY FOR β-D-GALACTOSYL-BOVINE SERUM ALBUMIN

Series	First additions	Second additions	Third additions	O.D. 420 mμ (× 10³)
1	E+BSA*	—	ONPG	288

6	—	Ab+ONPG	E	305
7	—	Ab+E	ONPG	321
8	—	Ab+ONPG	BSA	32
9	Gal-BSA+E	—	—	†

* BSA added as inert protein to prevent enzyme denaturation.

† 8 mgm. Gal-BSA and 300 μgm. N enzyme protein. No release of galactosyl groups as determined (*a*) by inability to detect free galactose with paper chromatography, and (*b*) no increase in sugar in supernatant, using anthrone method (ref. 14), after precipitation of Gal-BSA and enzyme with trichloracetic acid.

Enzyme (E), 0·1 ml. fraction *d* (Wallenfels *et al.*, *Biochem. Z.*, 331, 459; 1959) from induced *E. coli* containing 0·42 μgm. N enzyme protein; antigen (Gal-BSA), β-D-galactosido-phenylazo-bovine serum albumin (ref. 4), 0·2 ml. containing 2 μgm. N; antibody (Ab), 0·2 ml. absorbed rabbit antiserum (refs. 3 and 4) with 7·4 μgm. antibody N; bovine serum albumin (BSA), 0·3 ml. saline solution with 2·1 mgm. protein; *o*-nitrophenyl-β-D-galactoside (ONPG), 1·0 ml. of 3×10^{-3} *M* in phosphate buffer, *p*H 7·0. Tubes incubated at 30° C. 30 min. elapsed between first and second and between second and third additions. 10 min. after last addition, 2·0 ml. 0·1 *M* sodium carbonate added for colour development. Final volumes adjusted to 3·5 ml. as necessary. Optical densities corrected for protein absorption at 420 mμ.

Monod has stated[2] that the number of antibodies which may be produced by an organism of one genotype is infinite, whereas the numbers of enzymes inducible in one particular species of bacterium is quite limited. This conjecture may reflect the use of the extremely non-versatile organism *E. coli* for most induction studies. Consideration of the Pseudomonadaceae, for example, shows that the genotype of these micro-organisms allows for an almost unlimited number of enzyme inductions. From the classic example of Den Dooren de Jong[7] with *Pseudomonas putida* to the sequential induction experiments of Stanier[8] and of Dagley and co-workers[9], it is obvious that these microbes are capable of forming literally hundreds of enzymes which finally integrate fragments of unusual substrates into normal metabolic pathways. It is difficult to visualize "repressor substances"[10] being continuously synthesized for the myriad of enzymes which are inherent in the genome of Pseudomonads. Again, species differences in the induction of antibodies are also known. The most familiar example is the difference between rabbits and human beings in their ability to produce antibodies to purified polysaccharides. If one were to rely on the rabbit alone as a test animal, it might be concluded erroneously that purified polysaccharides are non-antigenic.

The formation of induced enzymes and antibodies has two requisites ; (*a*) the inducible organism must have the genetic potential to produce the specifically directed protein ; (*b*) the inducer must be present. Benzer[11] has demonstrated that the inducer does not act by selection in microbial enzyme induction. On the other hand, the Burnet–Lederberg "clonal-selection" hypothesis[12,13], which has been advanced to explain the phenomena of "self-recognition" and "actively-acquired tolerance", postulates that the antigen causes existing cells, which are capable of forming the specific antibody, to proliferate.

The observed parallelism presented here between the specificities of microbial enzymes and mammalian antibodies formed in response to the same determinant group suggests that, regardless of the mechanism, directed protein synthesis depends on the genetic endowment of a particular species to form a peptide chain the ultimate three-dimensional conformation of which is determined by the molecular configuration of the inducer.

Amino-Acid Patterns in Vitamin A-deficient Rats

VITAMIN A deficiency seems to cause negative nitrogen balance in young rats[1]. In a preliminary report, Abdulnabi and Bieri[2] indicated that in vitamin A-deficient as compared to pair-fed normal rats, the tyrosine- and phenylalanine-levels in the testes are increased and the threonine concentration of the liver shows a decrease. These results were obtained with microbiological assays, since paper chromatography failed to reveal any significant differences. We have compared the free amino-acid composition in blood, liver and kidneys of vitamin A-deficient and pair-fed normal rats by paper chromatography. Our results confirm the earlier observations of Abdulnabi and Bieri[2] and show significant increase in the phenylalanine- and tyrosine-levels, and a simultaneous significant decrease in the threonine values in all the three tissues of the deficient rats.

Weanling male albino rats of this Institute strain weighing 30–40 gm. were used in our experiment, and were kept on a vitamin A-free diet[3]. The control animals were given the same diet, but received, in addition, 150 µgm. of vitamin A once a week. The animals on the vitamin A-free diet alone stopped growing after about four weeks and began to show signs of A-deficiency. At this stage the control animals were pair-fed with the deficient ones. At the end of the sixth week, when severe symptoms of A-deficiency, as judged by acute anorexia and loss of weight, developed, the animals of both groups were killed. Blood was collected by heart puncture and liver and kidneys were excised. All the tissues were immediately cooled to 0°.

The free amino-acids of blood were extracted by the method of Giri *et al.*[4], and those of liver and kidneys were obtained by extraction with 80 per cent ethanol. The amino-acids were separated by circular paper chromatography on Whatman No. 1 filter paper and estimated colorimetrically[5]. Cystine, lysine, histidine, arginine, alanine, tyrosine, phenylalanine and the leucines were separated in a system[5] of *n*-butanol/water/acetic acid (40 : 50 : 10). The chromatogram was irrigated three times in order to ensure good separation. Valine and methionine were separated[6] in butanol/acetic acid/water (40 : 5 : 7). Triple irrigation was resorted to here also. Aspartic acid, glutamic acid, serine, glycine and threonine were separated in a phenol/water/*iso*propanol (70 : 25 : 5) system in an atmosphere saturated with 0·3 per cent ammonia (two runs)[7].

Chromatograms with the butanol/acetic acid/water systems were run in a thermostatically controlled room maintained at 18°. Standard amino-acids (10 µgm.) were always spotted along with the test materials. These served not only as reference, but also for final estimation of the unknown samples. It has been our experience that these procedures give consistent values.

The average patterns of free amino-acid in blood, liver and kidneys of seven groups of rats, each group consisting of one deficient and one normal pair-fed, are summarized in Table 1. Twelve out of the fifteen amino-acids estimated did not show any significant differences, whereas phenylalanine and tyrosine were markedly higher and threonine was consistently lower in all the three tissues of the deficient animals. The *P* values obtained by statistical analyses were less than 0·001 for these three amino-acids in all the tissues. It should, however, be mentioned here that Abdulnabi and Bieri[2] had pointed out significant depression of threonine in the liver and increases in phenylalanine and tyrosine values of testes only. Our results show more consistent changes in the three amino-acids in all the tissues examined.

Ershoff[8] had suggested that vitamin A may have some role in the proper functioning of the adrenal gland, and Lowe *et al.*[9] have actually shown histochemical changes in the same glands during vitamin A-deficiency. It has since been reported that the synthesis of glucocorticosteroid hormones is impaired in vitamin A-deficient animals[10]. This might be due to the failure of hydroxylation of the steroids. Production of adrenaline would require the introduction of three hydroxyl groups into the phenylalanine molecule. It is, thus, tempting to suggest

Table 1. Amino-acid Patterns in the Tissues of Vitamin A-deficient and Pair-fed Rats

Amino-acids	Average values for seven groups of rats					
	Blood (μgm./ml.)		Liver (μgm./gm.)		Kidneys (μgm./gm.)	
	A	*B*	*A*	*B*	*A*	*B*

that the accumulation of phenylalanine and tyrosine in the tissues of the vitamin A-deficient rats might be due to the impairment, in the damaged adrenal glands, of the hydroxylation reactions that are required for the production of adrenaline from phenylalanine.

Enzymatic Dephosphorylation of Adenosine Tetraphosphate

Adenosine tetraphosphate was discovered as an impurity in some commercial preparations of adenosine triphosphate[1,2] where its concentration may exceed 10 per cent of the total adenine[3]. It was also found in horse muscle[4] and possibly in rat liver[5].

The chemical properties of this nucleotide indicate that its structure is that of a straight chain of four phosphates attached to the carbon 5′ of adenosine:

adenine—ribose—P—P—P—P

Three of its four phosphates are acid labile[1,6]; the compound has two neighbouring hydroxyl groups[4,7], three primary phosphate groups (unpublished work) and only one secondary phosphate group[7]. In the following experiments the new nucleotide was dephosphorylated in the presence of specific enzymes.

A *b*-nucleotidase preparation was obtained from potato juice and purified by precipitation with alcohol and chloroform, adsorption on alumina gel and fractionation with ammonium sulphate. When tested at *p*H 9·5 and in the presence of 8 m*M* magnesium chloride, the isomer 3′ (or *b*) of adenylic acid was the only substrate hydrolysed, whereas the isomers 2′ (or *a*) and 5′, adenosine diphosphate, triphosphate and tetraphosphate were not. This indicated that adenosine tetraphosphate has no phosphate group attached to the carbon 3′.

An apyrase was also obtained from an acetone powder of potato juice and further purified by ammonium sulphate fractionation at *p*H 4·5. When tested at 40° C. and *p*H 6·5 in the presence of 3 m*M* calcium chloride and of 0·01 per cent serum albumin, the preparation liberated about 345 μgm. of orthophosphate per μgm. of enzyme preparation per hour, with 7·5 m*M* adenosine triphosphate as substrate. Compared with this figure taken as 100, adenosine diphosphate and tetraphosphate were hydrolysed more slowly (28 and 12 per cent respectively). In the presence of higher enzyme concentrations, adenylic acids (isomers 3′ and 5′ only), inorganic pyrophosphate and β-glycerophosphate were very slowly hydrolysed (0·2–0·5 per cent of the rate measured with adenosine triphosphate).

When a relatively large amount of this enzyme preparation was incubated with a small amount of adenosine tetraphosphate, more than three phosphates could be liberated per mole of adenine. This indicates that the apyrase activity was followed by the nucleotidase activity of the preparation. Since the nucleotide has no phosphate group on carbon 3′, and since the enzyme preparation has no measurable 2′-nucleotidase activity, it follows that the 5′-nucleotidase activity must be responsible for the last phosphate liberated.

Finally, the adenylic acid produced during the enzymatic hydrolysis was chromatographed on 'Dowex-1 formate' according to Cohn[8] and shown to be the 5′-isomer exclusively. The same 5′-isomer had been identified enzymatically after a mild acid hydrolysis[4].

The evidence provided by the enzymatic dephosphorylation of adenosine tetraphosphate confirms the structure proposed on the basis of its chemical properties.

It is hoped to publish the details of these experiments in the *Bulletin de la Société de Chimie biologique*.

Ninhydrin Assay in the Presence of Thiol Compounds

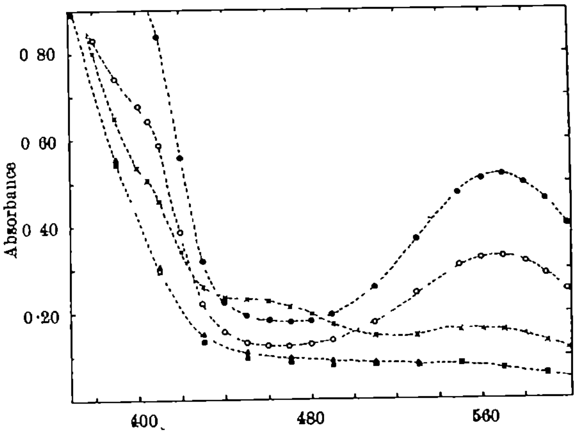

Fig. 1. Absorption spectra of the products produced by reaction with ninhydrin. ○, 0·10 μmole leucine; ×, 0·16 μmole cysteine; ●, 0·16 μmole cysteine + 4·0 μmoles NEM; △, ninhydrin reagent blank; □, ninhydrin reagent + 4·0 μmoles NEM

Moore and Stein[1] reported that the reaction of cysteine with ninhydrin is an exception to the general reaction of α-amino-acids with this reagent and the absorption curve of the reaction products is somewhat similar to that of proline and hydroxyproline (Fig. 1). They found that if the neutral protein hydrolysates were allowed to stand at room temperature for 24–28 hr. or if they were adjusted to *p*H 8 with sodium hydroxide and allowed to stand at room temperature for 4 hr. the cysteine–ninhydrin reaction product gave an absorption spectrum identical to that produced by cystine[1,2]. It is usual to include cysteine, mercaptoethanol, 2,3-dimercaptopropanol-1 or some other thiol compound as an activator for sulphydryl enzymes. When these are used for the activation of proteolytic enzymes such as ficin and papain the thiol compound ($10^{-2} - 10^{-3}$ *M* solutions) is not completely oxidized to the disulphide during the reaction procedure. The presence of the sulphydryl group then interferes with the usual ninhydrin determination as shown in Table 1 (col. 7). The presence of cysteine introduces two errors; first, during the enzymatic reaction it is partially oxidized to cystine (an unpredictable amount), and second, the cysteine remaining reacts with the ninhydrin reagent to give a red colour which interferes with the quantitative reaction of ninhydrin with the amino-groups. The presence of 0·1 μmole of mercaptoethanol in the modified ninhydrin reaction does not affect the quantitative determination of leucine (Table 1, col. 6), but, if the concentration of this reagent is increased to 10 μmole, leucine does not give a characteristic reaction product having a maximum absorption at 570μ but rather a red colour with an absorption maximum around 450 mμ is produced.

There would appear to be two solutions to this problem; first, the sulphydryl group could be oxidized to the disulphide in an alkaline medium, and second, the sulphydryl group could be blocked by reaction with a suitable reagent. Alkaline oxidation of the sulphydryl group of cysteine was found to proceed rather slowly at room temperature and did not give a quantitative conversion to cystine as measured by the ninhydrin method. Alkalis are known to have a destructive effect on certain amino-acids such as cysteine, cystine and arginine[3] and to cause racemization of amino-acids. N-ethylmaleimide reacts rapidly and quantitatively[4,5] with the sulphydryl group and has been used to prevent the oxidation of cysteine to cystine during separation by paper chromatography[6,7]. As shown by the results in Table 1 (compare cols. 2 and 3) leucine cannot be determined quantitatively in the presence of 4·0 μmoles of N-ethylmaleimide by the usual ninhydrin reagent[8]. If the amount of hydrindantin in the ninhydrin reagent is doubled, however, leucine (and other amino-acids tried) can be determined quantitatively in the presence of N-ethylmaleimide (Table 1, cols. 4 and 5). By the use of N-ethylmaleimide, a mixture of leucine and cysteine can be determined quantitatively (Table 1, col. 8) and the absorption spectrum of the product formed by the reaction of ninhydrin with the S-substituted cysteine is identical with that produced

Table 1. QUANTITATIVE DETERMINATION OF LEUCINE IN THE ABSENCE AND PRESENCE OF N-ETHYLMALEIMIDE (NEM), CYSTEINE AND MERCAPTOETHANOL (ME)

(1) Leucine (μmoles)	Optical density at 570 mμ						
	(2) Leucine*	(3) Leucine + NEM† (4·0 μmoles)	(4) Leucine‡	(5) Leucine + NEM (4·0 μmoles)	(6) Leucine + ME (0·1 μmole)	(7) Leucine + Cysteine (0·16 μmole)	(8) Leucine + Cysteine (0·16 μmole) NEM (4·0 μmoles)
0·050	0·124	0·056	0·119	0·123	0·126	0·221	0·569
0·100	0·255	0·139	0·263	0·261	0·265	0·352	0·692

* With the usual ninhydrin reagent (ref. 8). The sample was diluted to 2·0 ml. with water and then 1·0 ml. ninhydrin reagent added. After colour development, 5·0 ml. of 50 per cent (v/v) ethanol–water was added.

† The NEM is made up as a 2·02 *N* solution in 4·0 *N*, *p*H 5·5 acetate buffer and is added prior to addition of ninhydrin reagent.

‡ With ninhydrin reagent containing twice the usual amount of hydrindantin.

with leucine (Fig. 1). A study of the rate of reaction of N-ethylmaleimide with cysteine under the conditions employed here showed that the reaction goes to completion almost instantaneously. The N-ethylmaleimide is completely stable under acid conditions but should not be exposed, even momentarily, to alkaline conditions as it is converted to N-ethylmaleanic acid, which will then react with the ninhydrin reagent.

N-ethylmaleimide is used regularly in this laboratory to prevent the interference of sulphydryl groups with the ninhydrin assay of proteolytic activity and has been found to give very good results under a wide variety of conditions.

Chemical Oxidation of Uridine Diphosphate-Glucose to Uridine Diphosphate-Glucuronic Acid

THE importance of uronic acids in carbohydrate metabolism has only recently begun to be elucidated. The metabolism of inositol and ascorbate is known to involve uronic acid intermediates[1,2], and nucleotide-bound glucuronic acid has been implicated in hyaluronic acid synthesis[3].

Uridine diphosphate (UDP)-glucuronic acid has been prepared chemically by Khorana and may also be produced enzymatically by the action of UDP-glucose dehydrogenase[4]. Both these preparations are relatively time-consuming and require the separation of the product from several contaminating reactants and side products.

Marsh has reported the oxidation of glucose-1-phosphate to glucuronic acid-1-phosphate[5], and this report describes a similar oxidation of UDP-glucose.

Powdered platinum catalyst was prepared in aqueous solution from Adam's platinous oxide catalyst by hydrogenation at atmospheric pressure. 100 mgm. of reduced catalyst were suspended in 10 c.c. of water and introduced into a narrow vessel similar to that described by Marsh. The cylindrical vessel and sintered glass disk were attached to a U-shaped tube and immersed in a constant temperature bath; oxygen was bubbled through the solution at a rate adequate to keep the heavy catalyst particles in suspension. The UDP-glucose solution (63 μmoles) was then added, and oxygenation was allowed to proceed for 10½ hr. at a temperature of 55°, the *p*H being maintained between 7 and 8 by addition of 1 per cent potassium carbonate. This contrasted with the oxidation of glucose-1-phosphate at 45°, at which temperature no UDP-glucuronic acid was produced. At the end of the reaction the catalyst was removed by filtration, washed, and the filtrate and washings assayed for uronic acid content[6].

In order to show that the uronic acid produced was still nucleotide-linked, an aliquot was spotted for paper electrophoresis in 0·1 *M* citrate-phosphate buffer, *p*H 2. The electrophoresis was carried out at 800 V. for 2 hr., and the two ultra-violet absorbing spots were eluted from the paper with water; one of them gave a positive carbazole test, uridine spectrum, and showed a 1 : 1 ratio of uronic acid to uridine based on a molar extinction coefficient for uridine of 10,000, the other material being unreacted UDP-glucose. The UDP-glucuronic acid could also be assayed by enzymatic transfer to *o*-aminophenol as described by Dutton and Storey, utilizing a fraction of rat liver homogenate sedimenting between 500*g* and 37,000*g* as the enzyme system[7].

Use of 5 per cent palladium on charcoal as catalyst and oxygenation of the reaction mixture for 7 hr. resulted in no increase in the amount of uronic acid present, indicating that no oxidation had occurred.

Table 1. VARIATION OF YIELD WITH TIME

Time (hr.)	Yield* (per cent)
5·0	12
5·5	24
10·5	39

* Based on recovered UDP-glucose.

On the basis of recovered UDP-glucose, the best yield under the conditions studied has been 39 per cent. It is felt that the ease of isolation and relatively short reaction time required make the reaction feasible for the production of UDP-glucuronic acid.

Incorporation of [$1\text{-}^{14}C$]-*Iso*pentenyl Pyrophosphate into Polyisoprene

THE occurrence of 3-methyl-but-3-enyl-1-pyrophosphate (*iso*pentenyl pyrophosphate) as an intermediate in the enzymic synthesis of squalene from mevalonic acid, using yeast extracts, has been demonstrated by Bloch *et al.*[1,2], and by Lynen *et al.*[3]. The latter authors also quote an unpublished report by Arreguin that *iso*pentenyl pyrophosphate can be incorporated into the rubber of *Taraxacum kok-saghyz* latex. The *in vitro* conversion of mevalonic acid lactone into polyisoprene in the presence of natural rubber (*Hevea brasiliensis*) latex has been shown by Park and Bonner[4] and by Kekwick *et al.*[5]. In the experiments reported here it is demonstrated that *iso*pentenyl pyrophosphate, on incubation with fresh *Hevea brasiliensis* latex, is rapidly converted into high molecular weight polyisoprene with essentially 100 per cent efficiency.

Fresh latex was obtained from the young branches of two 18-months-old specimens of *Hevea brasiliensis* (Clone *P.B.* 86) growing in the tropical greenhouse attached to these laboratories. The [1-^{14}C]-*iso*pentenyl pyrophosphate (in amount too small for weighing) was dissolved in a suitable volume of 50 per cent aqueous alcohol to give the required radioactivity per unit volume. A known volume of this solution was used per incubation and evaporated to dryness under nitrogen in the incubation tube before addition of the fresh latex. The incubations were carried out under the conditions shown in Table 1. Each incubation tube was then spun about its axis to distribute the latex over the wall of the tube, and 10 drops of 5 per cent acetic acid in ethanol added. The thin film of coagulated rubber was covered with more coagulant for 5 min. and washed with water. It was next digested for 1 hr. at 100° C. with molar potassium hydroxide, washed with water, then with ethanol and finally extracted continuously with boiling redistilled ethanol for 16 hr. After evaporation of the residual alcohol on the rubber, 2 ml. of a 1 per cent solution of trichloracetic acid in dry toluene were added and the mixture stirred magnetically until the solution was homogeneous. The solution was then centrifuged at 10,000*g* and the supernatant quantitatively transferred to the counting vessel of an Ekco scintillation counter (type *N*664*A*). The residue left after centrifuging was negligibly small. The total count-rate of the toluene solution was determined by standard techniques, corrections being applied for the background count-rate and for counter efficiency, using an internal standard. The activity per unit volume of the original *iso*pentenyl pyrophosphate solution was determined similarly.

Table 1. INCORPORATION OF *iso*PENTENYL PYROPHOSPHATE INTO POLYISOPRENE

	1	2	3	4
Weight of latex (mgm.)	480	414	403	414
Total activity of *iso*pentenyl pyrophosphate added (c.p.m.)	6,360	16,380	6,360	16,380
Time of incubation	25 sec.	10 min.	30 min.	4 hr.
Temperature of incubation (° C.)	20	20	20	20
Percentage of initial radioactivity recovered in the rubber	24	102	98	100

Combined weight of rubber, after dialysis, from Exps. 2 and 4 = 115 mgm.

To establish that the radioactivity observed was due to high molecular weight polyisoprene and not to impurities in the rubber as radioassayed, the contents of two counting flasks (Exps. 2 and 4) were evaporated to dryness as a thin film and extracted with boiling ethanol for 16 hr. The rubber was then dissolved in chloroform containing 3 per cent w/w of ethanol; the solution was centrifuged to remove traces of insoluble material and dialysed against three changes of chloroform–ethanol solution for 96 hr. using alkali-treated cellulose membranes[5] which were readily permeable to β-carotene. The rubber was then ozonized by a high-efficiency procedure developed by Barnard and McSweeney (unpublished work) and converted to lævulinic 2 : 4-dinitrophenylhydrazone which was purified via the sodium salt, recrystallized twice from hot acetic acid and radioassayed by a standard gas counting technique[6] with a counter having an efficiency of 43 per cent.

The yield of lævulinic acid dinitrophenylhydrazone after reprecipitation from the sodium salt was 80 per cent, based on the weight of dialysed rubber taken for ozonolysis, and the observed specific activity of the twice recrystallized lævulinic acid dinitrophenylhydrazone was 736 c.p.m./m.mole carbon dioxide. This is equivalent to a total count-rate of 31,700 c.p.m. in the combined sample of dialysed rubber from Exps. 2 and 4, or 97 per cent of the total radioactivity initially added to the latex. Only the formation of a 1 : 4-poly*iso*prene could give the observed retention of activity, and if degraded to lævulinic acid with the same high efficiency as the inactive rubber, would need to have a molecular weight of at least 2,000. The dialysis procedure used during purification indicates that the synthesized material is in fact of considerably higher molecular weight. The results also show that the conversion of *iso*pentenyl pyrophosphate into products other than the high molecular weight polyisoprene must have been negligibly small.

We wish to thank Dr. Konrad Bloch for the generous gift of a sample of [1-^{14}C]-*iso*pentenyl pyrophosphate.

Nature and Composition of Dental Plaque

ALTHOUGH dental plaque is often mentioned in dental literature, its chemical composition has received little attention. Current literature frequently refers to "dentobacterial plaque" with the implication that it consists principally of bacteria. Manly[1], however, brushed teeth with a detergent prior to the collection of a film, which he called "brown pellicle". This material was free from micro-organisms and was considered to be principally protein. Vallotton[2] studied a similar deposit and found 8·9 per cent nitrogen and 24·8 per cent ash. Earlier, Dobbs[3] had also detected carbohydrate and lipid materials, in addition to protein and inorganic substances.

We have collected plaque from dentures after thorough brushing in a stream of running water. This material shows characteristics similar to those of the deposits described by Manly[1] and Vallotton[2]. Samples examined microscopically and by culture in various media were virtually sterile. Specimens sectioned in a vertical plane and examined by standard histochemical techniques appeared quite structureless except for occasional cocci on the surface. If, however, the washing stage was omitted, moderate growth was observed in the cultures. It seems likely, therefore, that bacteria, rather than constituting the main bulk of the plaque, are located at its surface. Different conditions may, of course, pertain on natural teeth.

Plaque collected after washing as described was dried *in vacuo* and stored at 2° C. until required. Powdered, weighed samples were stirred in aqueous suspension at room temperature using as a stirrer a small inverted filter funnel packed with 'Dowex 50'; the lower end being closed by a dialysis membrane. After 5 hr. the suspension was filtered and the residue dried and weighed. As a check that this method successfully removed all the free amino-acids, plaque was treated with dinitrofluorobenzene and thoroughly washed with organic solvents and water. Before the ion-exchange treatment dinitrophenyl derivatives of most of the common amino-acids were observed in the washings, but afterwards none was detected. In order to estimate inorganic material and free amino-acids it was necessary to ash samples before and after the ion-exchange treatment since this latter also removed most of the inorganic constituents. Lipid material was then estimated by extraction with chloroform/methanol (2 : 1) at room temperature. The resulting grey-brown powder contained 14 per cent nitrogen and only 2·0 per cent inorganic ash. Since all the common protein-forming amino-acids were liberated on hydrolysis this is afterwards referred to as 'plaque-protein'.

Although only occasional traces of carbohydrate were detected after hydrolysis of plaque-protein, extensive humin formation was usually observed. Hydrolysis in the presence of 'Dowex 50'[3] was found to be partially effective in preventing this. By adding known amounts of glucose to plaque-protein samples prior to hydrolysis, it was possible to estimate the extent of destruction of this carbohydrate. After hydrolysis the aqueous eluate from the resin was examined for hexoses and pentoses by the anthrone reaction[5,6] and by paper chromatography according to Wilson's method[7]. The acidic eluate was examined by the Elson–Morgan reaction both in solution and on paper chromatograms. Analytical results are summarized in Table 1.

Table 1. COMPOSITION OF DENTAL PLAQUE

Constituent	Mgm. percentage of dry plaque
Inorganic Ca^{2+}	2·7
Mg^{2+}	0·57
PO_4^{3-}	3·8
Total ash	10·6
Nitrogen (micro-Kjeldahl)	
Total	12·6
Protein nitrogen	11·1
Free amino-acids	11·6
Lipid	1·9
Carbohydrate	
Glucose	3·5–5
Pentoses	*c.* 1·0
Hexosamines	< 0·1

Aspartic acid and arginine were shown to be the principal N-terminal amino-acid residues by the dinitrofluorobenzene procedure[8]. These are present in approximately equimolecular amounts and only traces (< 10 per cent of the aspartic acid) of other N-terminal residues (serine and alanine) were observed. Treatment of a dinitrophenyl-plaque-protein suspension with chymotrypsin substantially reduced the amount of dinitrophenyl-arginine found after subsequent acid hydrolysis. By means of a talc column[9] it was possible to isolate from the soluble portion of the digest a dinitrophenyl-peptide, which yielded dinitrophenyl-arginine on hydrolysis. The protein mixtures obtained from saliva by centrifugation or precipitation showed, as expected, a wide range of different N-terminal amino-acid residues. These results suggest quite a marked degree of homogeneity in plaque-protein and imply a certain degree of selectivity in the mechanism involved in plaque deposition.

We are indebted to Mr. B. Steiger for the bacteriological and histochemical work and to Miss J. C. Riggott for technical assistance.

A New Leaf Copper Protein 'Plastocyanin', a Natural Hill Oxidant

THE occurrence in *Chlorella ellipsoidea* of a new copper protein, able to undergo reversible oxidation-reduction reaction, has been reported by one of us (S. K.)[1]. The methods of extraction and purification as well as some properties characterizing the substance have been described. This substance is distinguished from any of the oxidases by the fact that in its reduced form it is unable to react directly with molecular oxygen. Similar substances have since been found to occur in the green leaves of various higher plants (for example, spinach and *Chrysanthemum coronarium*). In view of its localization in the chloroplasts, and its characteristic blue colour in the oxidized form, the name 'plastocyanin' is proposed for this copper protein. Further work has been done to elucidate the behaviour of plastocyanin during photosynthesis. In this communication, the photoreduction (Hill reaction) of this substance and its effect on the photo-reduction of other known Hill reagents are briefly described.

Spinach, obtained from a local market, served as the starting material for the preparation of plastocyanin and grana. Details of the procedures devised for extraction and purification of plastocyanin will be published elsewhere. In brief, the substance was extracted from the acetone powder of ground spinach leaves with 0·01 *M* phosphate buffer, *p*H 7·0, and the extract was fractionated with ammonium sulphate. The precipitate obtained between 50 and 100 per cent saturation with ammonium sulphate was dissolved and dialysed against 0·02 *M* phosphate buffer, *p*H 7·0, and placed on a column of diethylaminoethyl cellulose equilibrated with 0·02 *M* phosphate buffer, *p*H 7·0. The column was successively washed with increasing concentrations of phosphate buffer, *p*H 7·0, and finally the substance was eluted with a 0·2 *M* solution of the same buffer. By repeating the ammonium sulphate fractionation and column chromatography, a highly purified preparation of plastocyanin is obtained. The purity index of the preparation thus obtained, expressed as the ratio of the extinction at 280 mμ to that at 597 mμ (maximum of absorption in the visible region), was found to be as low as 1·2.

To prepare grana, 100 gm. of spinach leaves were homogenized for 40 sec. in a Waring blendor with 150 ml. of sucrose solution (0·4 *M* sucrose, 0·01 *M* potassium chloride and 0·01 *M* phosphate, *p*H 7·0). The homogenate was forced through cloth and the resulting fluid fractionated by centrifugation, and the pellet obtained between 1,000*g* (5 min.) and 10,000*g* (10 min.) was washed three times and finally re-suspended in the sucrose solution.

To test the photo-reduction of plastocyanin, the reaction mixture containing plastocyanin and washed grana was illuminated with a tungsten lamp (100 W.) at a distance of 15 cm. The reduction of plastocyanin was followed by measuring the optical density at 597 mμ alternately under light and dark conditions (Fig. 1). In the light, plastocyanine was steadily reduced until complete reduction was achieved. During the dark periods between the light periods there was no reduction, nor was any oxidation of the substance observed. On addition of ferricyanide after the completion of photo-reduction, the recovery of optical density at 597 mμ to the original level was readily obtained, thus indicating that the observed optical changes were due to the reduction of plastocyanin. Potassium cyanide, at a concentration of 10^{-3} *M*, was found to be without effect on this photo-reduction. The reaction was also scarcely affected by sodium azide at the same concentration. On the other hand, *o*-phenanthroline, known to be a potent inhibitor of the Hill reaction, showed a marked inhibition, suppressing the reduction-rate by 75 per cent at 10^{-3} *M*. Although a direct proof of evolution of oxygen accompanying photo-reduction of plastocyanin has not yet been obtained, it may be justifiable to consider the substance under investigation to be a natural Hill oxidant occurring in the chloroplasts of green plants.

In another set of experiments the effect of plastocyanin was observed on the rate of the Hill reaction when other Hill reagents served as oxidants. Although the time-course of the reaction was somewhat complicated by an initial lag-phase, about two-fold stimulation in the rate of reduction of the dye was achieved by the addition of relatively minute amounts of plastocyanin in addition to the main Hill reagent (2,6-dichlorophenol indophenol, in this case). The experimental results shown in Fig. 2 may be best accounted for by assuming that plastocyanine in the initially oxidized state exerts a competitive inhibition of the reduction of the indophenol dye, while in its increasingly reduced state it entails an acceleration of reduction of the dye, presumably by acting as an electron carrier. In fact, it will be seen from the two lower curves in Fig. 2 that the duration of the lag period is roughly proportional to the amount of added plastocyanin. In similar experiments, but with mammalian cytochrome *c* as Hill oxidant, the addition of plastocyanin also caused a strong stimulation of photo-reduction.

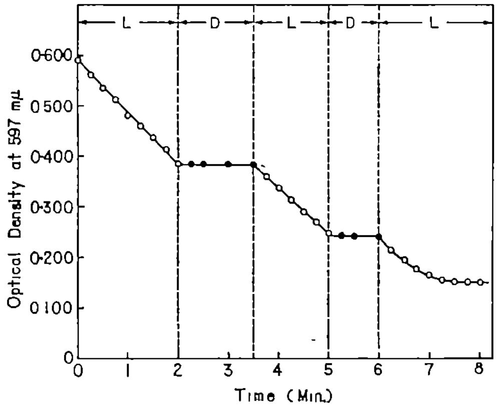

Fig. 1. Photo-reduction of plastocyanin in the presence of spinach grana. Reaction mixture: 150 μmoles phosphate, *p*H 7 0; 30 μmoles potassium chloride; 1,200 μmoles sucrose; plastocyanin (optical density at 597 mμ, 0 44) and grana equivalent to 9 μgm. chlorophyll; total volume 3·0 ml. Reduction of plastocyanin was determined spectrophotometrically at 597 mμ in air (15° C.). Reaction mixtures were illuminated with a 100-W. tungsten lamp (*L*) or kept dark (*D*) for the periods indicated, and then readings of optical density were made by inserting the cuvette into the cell-holder of the spectrophotometer

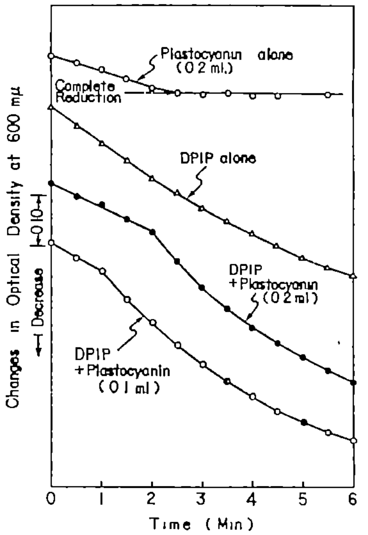

Fig. 2. Effect of plastocyanin on photo-reduction of 2,6-dichlorophenol indophenol (*DPIP*) in the presence of spinach grana. Reaction mixture: 150 μmoles phosphate, *p*H 7 0; 30 μmoles potassium chloride; 1,200 μmoles sucrose; 0 7 μmole 2,6-dichlorophenol indophenol; grana equivalent to 4 9 μgm. chlorophyll, and indicated amounts of plastocyanin (0 1 ml. solution containing plastocyanin equivalent to optical density of 0 034 at 597 mμ; light path 1 cm.); total volume 3 0 ml. Reactions were measured as in Fig. 1; optical density determined at 600 mμ. Curves were plotted on optical density scale at arbitrary locations on the ordinate

These experimental results suggest that the new copper protein under investigation may play an important part in the photosynthetic mechanism in green plants.

PHYSIOLOGY

Alteration of the Growth of Mammalian Cells *in vitro* by Ecdysone Extract

In insects metamorphosis is controlled by a balance between juvenile hormone (neotenin) and metamorphosis hormone (ecdysone) with trophic neurosecretion responsible for periodicity[1-4]. Work on the reason for regression of atypical growths in *Drosophila*[5] during the larval stage implicated this hormonal mechanism in the observed behaviour[6,7]. As a result of this work, investigation of the possibility that hormones in invertebrates may have an effect on mammalian cells is in progress. In earlier work[8], there were suggestive regressions of transplanted tumours in mice when ecdysone was injected into individuals bearing transplants. Although the large amount of hormone required render this type of testing impractical except on a limited scale, the results were sufficiently encouraging to stimulate additional studies *in vitro*.

Ecdysone was extracted from fresh chrysalides of *Bombyx mori* preserved in methanol, and the fractions were tested for activity by utilizing the *Calliphora* test[9] (Parke, Davis and Co. kindly supplied facilities and personnel for initial phases of the extractions). Cultures of both sarcoma 180 and embryonic, murine fibroblasts were tested for possible alteration in growth after treatment with graduated concentrations of ecdysone, which was titrated in balanced salt solution after passing through a Seitz filter. Sarcoma 180 was grown subcutaneously in mice, and the tumours were removed aseptically on the fifth to seventh day following explantation when a diameter of 0·6–0·8 cm. was reached. After the tissue was minced in warm, balanced, salt solution containing penicillin and streptomycin, fragments 1·0 mm. in diameter were used for culture. The fragments were grown by the double coverslip method in chick-plasma clot, using medium consisting of Eagle's basal medium, calf serum, and chick-embryo extract. Similar methods were used to grow embryonic fibroblasts. The behaviour of experimental and control cultures was followed daily by means of photomicrographs, stained preparations, and time-lapse, phase cinémicrographs. Dosages of crude ecdysone used were 1, 12, 25 and 62 *Calliphora* units.

The growth of cultures of sarcoma 180 was obviously suppressed within 24 hr. in doses of 12 units or more, the effect increasing with concentration. An interesting aspect of this work has been rapid, initial growth of cells treated with ecdysone, with subsequent inhibition. Evidence of this is more subjective, whereas the evidence of inhibition with the extract is incontrovertible. Three criteria were used in evaluating the effect of the hormone. They were: the growth curve of the cells, the number of cells and the time the cells die. Treated cells reached a plateau of growth much earlier than the control cultures, which continued to grow. Also the number of cells was greater in control cultures, and, finally, death of the cells occurred earlier in the series treated with ecdysone. Results from experiments with the lowest dose found to be effective demonstrate the method of scoring (Table 1). The results obtained in 56 experiments with sarcoma 180 are included in Table 2.

Certain morphological and dynamic characteristics of the cells changed with the addition of ecdysone. There was diminution in size as well as in the number of cells, and the amount of cytoplasm as well as the number of pseudopodia were reduced in those treated.

Table 1. INHIBITION OF SARCOMA-180 WITH 12 *Calliphora* UNITS OF ECDYSONE

Table 2. EFFECT OF ECDYSONE ON SARCOMA-180 *in vitro*

No. of exp	Concentration ecdysone		Summary of results
	µgm. per culture	*Calliphora* units	
5	2·6	1	No alteration of growth
29	26·0	12	Inhibition begins day 2*
17	50·0	25	Inhibition begins day 1*
5	130·0	62	Almost complete suppression*

* Initial enhancement.

The distance which the cells migrated from the fragment was also diminished after treatment, and mobility of the cells was reduced by ecdysone as part of the general inhibition. Nuclear pycnosis, rounding up, and early death of cells were augmented with treatment, and an interesting granularity in late-treated cultures was very striking.

Ecdysone also altered the growth pattern of embryonic fibroblasts. The onset of growth was delayed by increasing concentration of the hormone until total inhibition occurred. The results of 63 experiments are summarized in Table 3. No initial stimulation of growth of these cells was observed.

Table 3. EFFECT OF ECDYSONE ON EMBRYONIC FIBROBLASTS *in vitro*

No. of exp.	Concentration ecdysone		Summary of results
	µgm. per culture	*Calliphora* units	
12	12	6	Growth begins day 2
24	25	12	Growth begins day 3
12	45	22	Growth begins day 4
15	80	40	Total inhibition

The presence of a threshold and the increase in effect up to total inhibition with increased dose of hormone all indicate that crude ecdysone inhibits the growth of both sarcoma 180 and embryonic fibroblasts. Two differences in the type of inhibition of sarcoma 180 in comparison with embryonic fibroblasts are of interest. First, there is a suggestion of initial enhancement of growth, with subsequent inhibition, in the case of sarcoma 180 which was not observed in the growth pattern of treated, embryonic fibroblasts. Secondly, sarcoma 180 grows initially in the culture, and the length of this period of growth is curtailed increasingly as the concentration of hormone is augmented. On the other hand, the time at which growth of embryonic fibroblasts begins is extended by the hormonal preparation from a threshold to complete inhibition.

Whether the increased granularity in older, treated cultures has some significance in connexion with the effect of the hormone on alteration of intracellular, enzymic activity is under scrutiny. Since a crystalline preparation was not used, the exact ingredient of the preparation responsible for the effect cannot be identified with certainty. However, the impression that the effect paralleled the concentration of the hormone according to bioassay rather than the weight of the preparation suggests that the hormone itself is responsible. One of the more interesting questions raised by this work is whether this mnemonic phenomenon with phylogenetic implications will become a useful means of altering certain aspects of cellular physiology at will. The possibility of introducing biological regulators into systems where they are effective, yet not normally present or active, is a provocative development.

Serum Iron and its Transport Mechanism in the Fowl

LITTLE work seems to have been done on iron metabolism in the fowl, especially in the field of transport by serum. First, we investigated this mechanism in various mammals[1] and later in the fowl[2-4]. Iron in the blood is attached to β_1-globulin (transferrin or siderophilin), the transport mechanism of which seems to be common to higher vertebrates; but we found in the hen bird that there is a special behaviour during the laying season[3,4].

It has been shown[5] that during the laying season the hens had a high level of serum iron. Using Ramsay's techniques[6,7], we were able to show that the values of serum iron are even higher than the total iron-binding capacity in the serum of laying hens and laying ducks[4].

We have studied four species: *Gallus domesticus*, *Meleagris gallopavo*, *Anas platyrhynca*, var. Kaki-Campbell and *Anser anser*. In each we determined serum iron values and the total iron-binding capacity using Ramsay's methods[6,7]. In addition, we have also calculated the saturation coefficient for siderophilin.

Table 1. SERUM IRON, TOTAL IRON-BINDING CAPACITY AND SATURATION COEFFICIENT IN CERTAIN BIRDS

Species	Sex and No. of specimens	Serum iron (γ Fe per cent)	Total iron-binding capacity (γ Fe per cent)	Saturation coefficient (per cent)
Meleagris gallopavo	♂ 10	70±16·2 (σ=48·7)	302·1±12·2 (σ=36·6)	24·7±5·4 (σ=16·2)
	♀ NL 11	104·9±14·5 (σ=45·2)	315·2±14·8 (σ=46)	33·6±4·4 (σ=13·9)
Gallus domesticus	♂ 23	102·5±4·8 (σ=22·4)	165±14·2 (σ=65·5)	67·8±3·9 (σ=18·1)
	♀ NL 23	129±10·4 (σ=47·8)	262±15 (σ=69)	51·7±4·1 (σ=18·9)
	♀ L 16	500±42·4 (σ=165·5)	272±21·8 (σ=85·1)	198±21·5 (σ=83·9)
Anas platyrhynca	♂ 6	159·1±50 (σ=110·2)	634·5±54·5 (σ=120·1)	25·5±7·3 (σ=16·1)
	♀ NL 6	132±18·5 (σ=40·5)	472±54·2 (σ=108·5)	28·4±2·1 (σ=4·3)
	♀ L 19	1,065±68 (σ=286·6)	504±32·9 (σ=131·8)	227·5±18·1 (σ=72·7)
Anser anser	♂ 7	163·8±16·1 (σ=38·7)	547·3±25·1 (σ=60·3)	29·9±2·3 (σ=5·5)
	♀ NL 6	160±10·5 (σ=23·1)	561±36·5 (σ=80·3)	28·9±1·9 (σ=4·2)
	♀ L 1	1·260	705	178·7

NL = not laying. L = laying.

Laying females show a considerable rise in serum iron, giving values higher than those for males and for non-laying females; these values are also different from those which were found in different mammals[1]. This rise has been observed especially in ducks and geese (Table 1). The difference in total iron-binding capacity is clearly marked in these species, although it is not so evident as the corresponding serum iron values. However, the differences for females during and outside the laying season for the same species are not statistically significant.

The values for the saturation coefficient of siderophilin are much increased (100 per cent) in the laying female.

It is surprising to see how the serum iron values are approximately doubled compared with the corresponding total iron-binding capacity. This resulted from the application of Ramsay's method[7] in the determination of total iron-binding capacity, where the use of magnesium carbonate to retain surplus iron causes at the same time a partial elimination of circulating iron.

Table 2. SERUM IRON BEFORE AND AFTER TREATMENT WITH MAGNESIUM CARBONATE AND TOTAL IRON-BINDING CAPACITY IN LAYING BIRDS

Species	No.	Serum iron (γ Fe per cent)	Serum iron after treatment (γ Fe per cent)	Total iron-binding capacity (γ Fe per cent)
Gallus domesticus	7	570±68·8 (σ=165·2)	244±36·6 (σ=88)	226·4±41·7 (σ=100·1)
Anas platyrhynca	11	1,183·1±136·7 (σ=424)	578·7±80·4 (σ=249·5)	533·2±59·6 (σ=185·3)

The determination of serum iron in serum previously treated with carbonate (200 mgm. magnesium carbonate + 2 c.c. distilled water + 1 c.c. serum, during 30 min. and centrifugation) gives a value for the laying female of approximately 50 per cent of that for untreated serum (Table 2). On the other

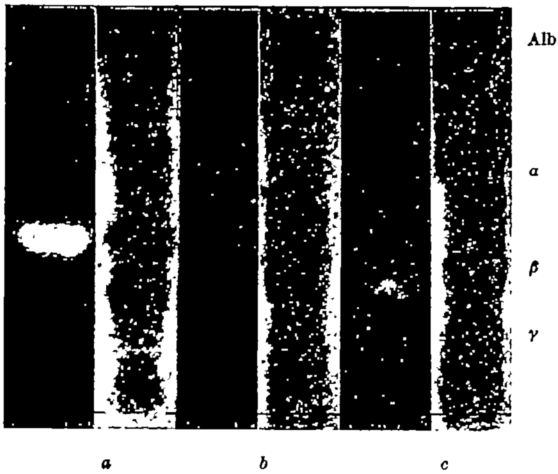

Fig. 1. Electrophoretic bands and their corresponding autoradiographs of the following sera: (*a*) Serum of a laying duck to which has been added iron-59 *in vitro* (1 ml. serum + 2 μgm. (12 μc.)). (*b*) Serum of a laying hen which has previously received by injection 2 μgm. iron-59 (12 μc.). (*c*) Serum of a laying hen to which has been added iron-59 *in vitro* (2 ml. serum + 2 μgm. (12 μc.))

hand, there are no significant differences using serum from females not in season or for serum from males treated in the same way.

It is to be noticed that the average value of total iron-binding capacity does not differ statistically from the serum iron concentrations determined after treatment with magnesium carbonate (Table 2).

In the laying fowl, iron metabolism shows a special character and its transport through the blood presents special characteristics. Two possibilities may be considered : (*a*) that iron travels bound exclusively to siderophilin, with one fraction firmly bound (total iron-binding capacity), and the other fraction more weakly bound and easily separated by the action of carbonate ; and (*b*), that besides the siderophilin other protein fractions take part in the transport of iron.

Recent work with iron-59 indicates that both mechanisms are in operation. In laying ducks, the addition of iron-59 *in vitro* to the serum shows constant fixation to the β-globulin (Fig. 1*a*), and the same behaviour is observed on injecting the radioactive iron into the laying hen (Fig. 1*b*). On the other hand, the addition of iron-59 *in vitro* to serum of laying hens is fixed to all the globulins, but preferentially to the β-fraction (Fig. 1*c*).

Evidence for the Granular Localization of Posterior Pituitary Hormones

ENDOCRINE organs are able to maintain high concentration gradients between their secretory cells and the extracellular fluid. The mechanisms for maintaining this gradient are not clear, although restraining the hormones within a semipermeable membranous structure could sub-serve this function. Herlant[1] and Brown and Hess[2] have shown that many hormones of the anterior pituitary are stored in a particulate form. In addition, the work of Hillarp *et al.*[3] and Blaschko and Welch[4] indicates that adrenaline and noradrenaline are stored in granules within the adrenomedullary cells.

There is abundant histological and morphological evidence that the neurohypophyseal hormones are found in association with material of a granular or colloidal nature. Rosenfeld[5] found that following long-term ultracentrifugation oxytocic and pressor activity was confined predominantly to the sediment.

The following experiments indicate that by a relatively simple centrifugation technique a sedimented fraction can be obtained from sucrose homogenates of neurohypophyses that contains very much more of the antidiuretic hormone and oxytocic hormone than does the supernatant. When distilled water is added to this sediment it releases the hormones. This suggests that they are stored in the neurohypophyses within a membranous structure.

Cattle neurohypophyses were removed within 60 min. of killing. The glands were kept chilled while being pressed through a 0·5-mm. porcelain sieve. The pressed tissue was then homogenized in 0·55 *mM* sucrose using a power-driven plastic rod within a loose-fitting glass test-tube. Comparative experiments suggested that this concentration of sucrose was more suitable than 0·25 *M* or 0·88 *M* sucrose or saline. The homogenates were then centrifuged at 1,000*g* for 10 min. The sediment was discarded and the supernatant recentrifuged at 50,000*g* for 20 min. The sediment was washed five times with sucrose, and after the last wash the sediment was resuspended in distilled water of the same volume as the last sucrose wash. The sediment was then removed by centrifugation at 50,000*g* and the hormonal activities determined in the supernatant from the last sucrose wash and in the distilled water. The antidiuretic activity was determined by Dr. Bengt Andersson[6] on the hydrated goat. The oxytocin assays were performed on the rat uterus. The chicken blood-pressure method was also used. The results are expressed as total activity in the water-ruptured granules (sediment) or in the supernatant from the sucrose-washed granules (supernatant).

Table 1. UNITS OF HORMONAL ACTIVITY OBTAINED FROM 2·5-GM. CATTLE NEUROHYPOPHYSEAL TISSUE

	Sediment *B.P.*-6	Supernatant *B.P.*-5
Antidiuretic activity	120	3·7
Oxytocic activity	108	0 60

The results indicate that in the gravitational fields employed the hormonal activities were predominantly located in the sedimentable fractions. The release of the humoral activity from the sediment by distilled water suggests an osmotic rupturing of a membranous structure, as has been shown for the catechol-containing granules.

It is interesting to speculate on the possible physiological significance of the granular localization of hormones. As a working hypothesis, we would suggest that the adequate stimulus to an endocrine gland may selectively alter the integrity of the granular membrane restraining this gland's hormonal secretions.

We wish to thank Dr. Bengt Andersson for assaying the antidiuretic activity in our preparations. The senior author is grateful to Prof. U. S. von Euler for the opportunity of carrying out this work in his laboratory.

This work was supported by a postdoctoral research fellowship from the Public Health Service to one of us (S. S.).

Mucopolysaccharides and Thyroid Function

In diseases with intense tissue disintegration, in agreement with reports in the literature[1,2], the mucopolysaccharide (hexosamine)-level of blood was found to increase : thus in tuberculosis and in cancer it was found to increase from the normal level of 83 mgm. to 120–160 mgm. per 100 ml. In tuberculosis[3] and C_3H mouse carcinoma[4], the local formation of neutral mucopolysaccharides could be demonstrated. The neutral mucopolysaccharides—formed in the hypoxybiotic areas of the diseased tissues—are drained through the lymphatic vessels. They can be traced in the blood, and so the increase of the mucopolysaccharide content can be interpreted in terms of a pathological mechanism. It is known that, after healing, the mucopolysaccharide content returns to the normal level.

The question arose as to which organ or neuroendocrine system regulates the normal mucopolysaccharide content of the serum. According to results in the literature, the mucopolysaccharide-level is increased in myxœdema[5,6]. Attention was therefore focused on the thyroid gland. The colloid of the thyroid gland gave a positive reaction with the periodic–Schiff reagent. Thus the possible role of the thyroid gland became more comprehensible. The effect of some hormones has already been discussed by Boas and Foley[6] and by Dorfman and Schiller[7].

We investigated the mucopolysaccharide content of 16 hyperthyroidic patients of the I. Medical Clinic of Debrecen. We used the method of Elson and Morgan described by Winzler and modified by Szabolcs and Tankó[8]. By the latter modification—nearly the whole procedure is carried out in the same tube—the limit of error is less than 3 per cent. The results for these patients are represented in Fig. 1. Some of the patients were only slightly hyperthyroidic, or had nearly normal thyroid function. However, the average mucopolysaccharide content was considerably less than the normal level. On the other hand, the mucopolysaccharide content of the blood of hypothyroidic patients was found to be higher than the normal, and considerably higher than the mucopolysaccharide-level of hyperthyroidic patients.

In evaluating the significance of the mucopolysaccharide-level of a patient suspected of hypothyroidism, we have to consider that a high mucopolysaccharide-level occurs not only in cases of myxœdema but also in several diseases with increased disintegration of tissues (tuberculosis, carcinoma, rheumatism, pneumonia, etc.). Thus a high mucopolysaccharide-level (caused, for example, by pneumonia) may eventually mask hyperthyroidism. However, a low mucopolysaccharide content is found to be connected with hyperthyroidism, provided that there is no insufficiency of liver or kidney. To make a diagnosis, several other diagnostic methods should be tested.

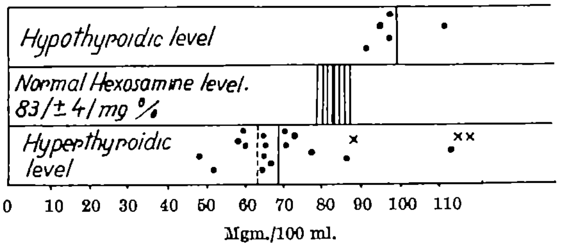

Fig. 1. Diagram illustrating the hexosamine-level of hypothyroidic (average 99·6 mgm. per 100 ml.) and hyperthyroidic (average 68·9, with correction 65 mgm. per 100 ml.) patients. + and + + , two weeks later the hexosamine-level of these patients proved to be 70 and 68 mgm. per 100 ml., respectively

We wish to direct attention to the connexion existing between the local or general hypoxybiosis, the formation of mucopolysaccharides and thyroid function.

Experimental Data concerning the Connexion between Thyroid Function and Mucopolysaccharide (Hexosamine)-Level

In the preceding communication it was demonstrated that the mucopolysaccharide content of the blood (normally 83 ± 4 mgm. hexosamine per cent) is decreased in hyperthyreosis (65 mgm. per cent on average) and increased in myxœdema (100 mgm. per cent on average). We have tested these observations on experimental animals.

Experiments on rats applying heat and cold stress failed to give evaluable results. Thyroidectomy was carried out on 6 dogs. Their mucopolysaccharide (hexosamine)-level was found to increase within 3–6 weeks by 44 per cent, and was accompanied by clinical signs of myxœdema. Afterwards, thyroid hormone ('Thyroxyne', Roche, 1 mgm. per day, the dogs weighing 10–12 kgm.) was administered for 3–4 weeks ; the increased hexosamine-level of the dogs, which fluctuated for one or two weeks, decreased below the original normal level. Methylthiouracyl (0·05 gm. 4-methyl-2-thiouracyl per kgm.) was administered to a further 6 dogs (10–12 kgm.). The hexosamine-level of these dogs increased within 2–5 weeks by an average of 30 per cent. Thereafter these dogs received also thyroxine (1 mgm. per day continuously). Three of the dogs died prematurely. The hexosamine-level in the remaining three dogs decreased within 2–8 weeks to an average of 72 per cent of the original level. Administration of thyroxine to 4 untreated dogs produced a decrease in the hexosamine-level. The statistical evaluation of these two experiments gave a significant difference (Prof. Gyires, Department of Applied Mathematics). The results obtained on untreated dogs were not evaluated statistically, the number of the experimental animals being too small, and the changes in these experiments were only in one direction.

These experiments showed that experimental thyroidectomy (6 dogs) and methylthiouracyl treatment (6 dogs) caused a significant increase of the mucopolysaccharide (hexosamine)-level of the blood serum, whereas thyroxine treatment (11 dogs) brought about a significant decrease of the mucopolysaccharide-level of the serum. It may be added that thyroxine still had this effect even after thyroidectomy.

Our previous observations on man on the correlation of the decrease of the hexosamine-level in cases of hyperthyreosis were confirmed by our experiments on dogs. By the administration of thyroxine, the hexosamine-level could be decreased. On elevating the hexosamine-level by previous thyroidectomy or by prolonged administration of methyl thiouracyl, the effect of thyroxine became more manifest. By using the method of thyroidectomy, we were able to confirm the findings of Boas and Foley that thyroidectomy on rats produced a sustained increase in the hexosamine-level of the blood. Our experiments on dogs using thiouracyl and our observations on man regarding myxœdema were supported by the experimental results on hyperthyreosis.

Thus we conclude, as regards dogs and man, that the decrease of thyroid function results in an elevation of the mucopolysaccharide (hexosamine)-level, while the sustained increase of thyroid function results in a decrease of the mucopolysaccharide (hexosamine)-level of the blood.

Identification of a Compound found during Separation of Purines in Human Urine

The purine bases of normal human urine have been separated, identified and quantitatively estimated[1-3]. During these investigations several additional unknown compounds appeared with the purines; they were separated and designated *E*, *W*, *S* and *Z*.

In our search for abnormal purines in the urine of patients with cancer and leukæmia, compound *Z* was found in high concentration in the urine of one leukæmia patient. From examination of a limited number of urine samples, it appeared that normal subjects and leukæmia patients in remission excreted large amounts of this material when compared with patients with cancer and active leukæmia. Identification of this compound was therefore undertaken.

Compound *Z* was isolated from a urinary concentrate by gradient elution chromatography on a column of 'Dowex 50'[1]. Further purification was accomplished by ascending 2-dimensional paper chromatography. Papergrams containing compound *Z* were sprayed with several reagents, but only the Jaffe reagent gave a positive reaction. The finding of a single red spot with this reagent in the position occupied by spot *Z* (rendered visible by ultra-violet light) suggested that this compound might be creatinine. Overlays of creatinine and *Z* in four different solvents gave no separation of these compounds.

The ultra-violet absorption spectrum of *Z* is unlike that of purines in that it has only end-absorption between *p*H 2 and 5, and above 11. It has, however, an absorption maximum between *p*H 5·8 and 11 at 232 mμ. A pure sample of creatinine exhibits the same ultra-violet absorption characteristics.

The insolubility of a silver–purine complex in acid solution is the basis for Weissmann's[1] separation of purines from creatinine, amino-acids, and pyrimidines. In order to determine whether creatinine could be precipitated with acid silver nitrate, a solution of similar creatinine concentration to that found in the urinary concentrate was prepared; this contained 10 mgm. creatinine/ml. water. Addition of acid silver nitrate gave a precipitate which was filtered, washed, and decomposed with hydrochloric acid under the same conditions as a urinary concentrate. The resulting solution on analysis by the Jaffe reaction contained 0·3 per cent creatinine. From this, it is evident that although 99·7 per cent of the creatinine remains in solution during silver nitrate precipitation, the presence of a high concentration of creatinine in the urinary concentrate is sufficient to exceed the solubility product of the silver–creatinine complex, and therefore the residual 0·3 per cent is carried through the procedure and appears with the purines.

Muscarinic Receptors

The (+)-isomers of acetyl-α- and acetyl-β-methylcholine are respectively about 10 and 250 times more active as muscarinics than their corresponding enantiomorphs (Table 1). We have recently established the configuration of these (+)-isomers as I and II [1,2]; their configurational identity with (+)-muscarine (III) [3] about C_5 is indicated in Fig. 1.

The muscarinic activity of muscarine is considerably reduced in the isomers in which the CH_2, CH_2NMe_3 or OH groups are inverted[4]. If the quaternary N group and the ether O of (III), lying almost in a plane, form the chief two centres for drug-receptor association (the OH group acting as a secondary association site), then association with receptor must involve the lower surface of (III). Inversion of the methyl group of (III) would then produce a steric barrier against such association. Replacement of this methyl group by a hydrogen atom considerably reduces activity[5], probably because of reduction of

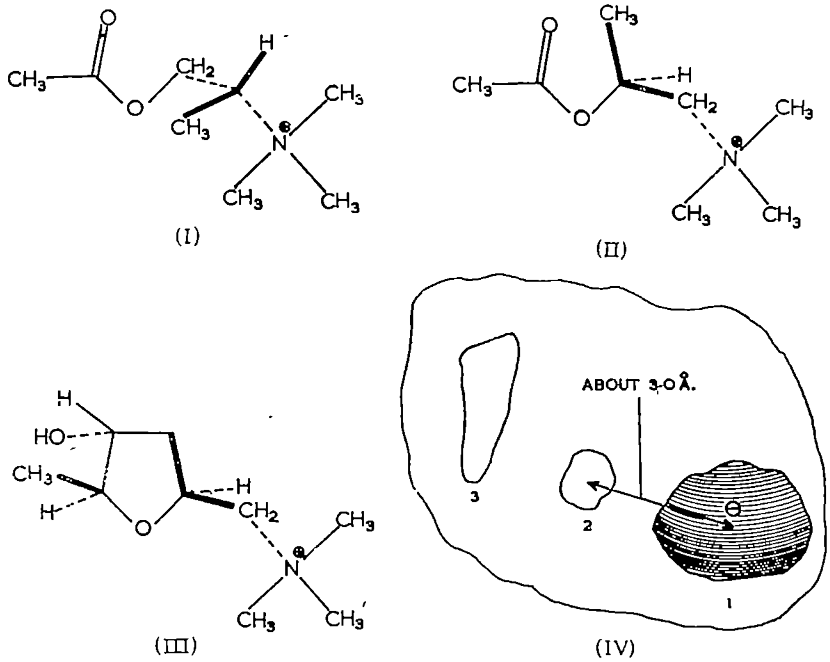

Fig. 1. Configurational relationship of the (+)-isomers of acetyl-α- and acetyl-β-methylcholine with (+)-muscarine. (I) Anionic cavity negatively charged to accommodate quaternary nitrogen. (II) Positively charged point accommodating ether linkage of muscarine or ester linkage of acetylcholine and its analogues. (III) + charged area to accommodate OH of muscarine, $\rangle C{=}O$ of acetylcholine analogues or double bond of furan analogues of muscarine, etc.

electron density on the ether oxygen atom rather than by reduction in the availability of van der Waals' forces for bonding. Similarly, the reduced activity of (V; $R = H$)[6] as compared with (V; $R = Me$) and (VI; $R = H$) with (VI; $R = Me$)[7] is explicable. Because of the rigidity of these molecules, the complementary muscarinic receptor may tentatively be considered as depicted in IV (ref. 8).

The (+)-isomer of acetyl-β-methylcholine can adopt a conformation (I) complementary to that of the depicted receptor (IV), whereas the (−)-isomer cannot do so. The 250-fold greater activity of the former is probably an under-estimate of the true difference in drug-receptor interactions, since acetylcholinesterase is known to hydrolyse the former much more rapidly than the latter[9]. The (+)-isomer of acetyl-α-methylcholine, because of the increase in steric size in the vicinity of the cationic head, unlike acetylcholine, cannot present a surface completely

$CH_3COOCH_2\underset{CH_3}{\underset{\vert}{C}}H\overset{+}{N}Me_2Et$	I′	(±) (−) (+)	264 1,980 170	248–286 1,695–2,310 156–186	12	149 1,920	22

complementary to (IV). The difference in the possible associating surface of the enantiomorphs is much less marked in the α- than in the β-isomers of acetylmethylcholine. Observed differences in the muscarinic activities of the above isomers is therefore explicable in terms of differences in their fit at the muscarinic receptors (IV).

PATHOLOGY

Neural Tissue and Pulmonary Lesions in Normal and Irradiated Rats Injected with Homogenized Homologous Lung Tissue mixed with Freund's Adjuvant

STARTING from the assumption that auto-immune processes occur in irradiated animals as well as normal animals[1], we have succeeded in inducing experimental allergic encephalomyelitis in irradiated rats[2]. In order to examine the specificity of that phenomenon, several homogenized organ tissues mixed with adjuvant were used, such as brain, liver, lung and pancreas. Of the organs used in these investigations, lung tissue mixed with adjuvant produced the symptoms of experimental allergic encephalomyelitis.

In the experiments 70 albino rats of mixed breed, weighing about 180 gm., were used. The animals received injections of homogenized homologous lung tissue mixed with adjuvant. The ingredients of the antigen mixture were added as recommended by Lipton and Freund[3]. 1·0 ml. of the antigen mixture was divided into four doses of 0·25 ml. each and injected subcutaneously. The doses were given simultaneously in the ventral part of the abdomen, two on each side. The irradiation dose was 600 r. (220 kV., 15 m.amp., 0·5 copper, 1·0 aluminium, r = 40 cm.; the dose-rate was approximately 120 r./min.).

The injections were given 24 hr., 3 hr., 30 min. before, and 30 min., 3 hr. and 24 hr. after, irradiation. One group was not irradiated.

Diagnosis of experimental allergic encephalomyelitis was based on the paralysis of limbs and/or marked atactic gait, arthritis was detected by inspection of paws, and lung lesions were determined by inspection of histological sections stained with hæmatoxylin and eosin. Sections of medulla spinalis were also inspected microscopically, after staining with hæmatoxylin–eosin.

Table 1. INCIDENCE OF EXPERIMENTAL ALLERGIC ENCEPHALOMYELITIS (EAE) AND ARTHRITIS IN NORMAL AND IRRADIATED RATS BEFORE AND AFTER IRRADIATION

Time of antigen injection	Rats suffering from EAE	Arthritis
Control (not irradiated)	15/20	6/15
− 24 hr.	0/10	—
− 3 hr.	7/10	—
− 30 min.	8/10	2/8
+ 3 hr.	7/10	2/7
+ 24 hr.	7/10	—

The results presented in Table 1 show 70–80 per cent incidence of experimental allergic encephalomyelitis in normal and irradiated rats. Only some of the animals with symptoms of experimental allergic encephalomyelitis had arthritis, whereas pulmonary lesions of various degrees were observed in all animals. The encephalomyelitic symptoms were manifested not earlier than four weeks after injections, which is later than when brain plus adjuvant is used. On the other hand, all the animals recovered in the former instance, whereas this was not the case with encephalomyelitis induced by brain tissue.

Histological sections of brain, medulla spinalis and lung were examined. In brain sections, no alterations could be detected. In the lumbar region of medulla spinalis, typical perivascular infiltrations with cells of mononuclear type, and in some regions diffuse scattered inflammatory cells, were observed. In the pulmonary interstitium and in the interalveolar septa, which became plump and protruded into the alveolar lumen, a strong infiltration of inflammatory cells of mononuclear type occurred.

Although it is not possible to explain the non-appearance of experimental allergic encephalomyelitis in the group of rats injected 24 hr. before irradiation, the incidence of pulmonary lesions and encephalomyelitis in normal and irradiated animals leads us to conclude that auto-immune processes occur also in the irradiated organism.

In this instance it is not possible to explain the antigenic relations between brain and pulmonary tissue. A careful examination of the remaining organs and tissues, and the antigenic relationship between them, will be the subject of further investigations.

Inhibiting Effect of Nicotinamide and Diphosphopyridine Nucleotide on the Methylcholanthrene Sarcoma in Rats

RECENTLY, Oide[1] reported that when a pellet of nicotinamide was intrasplenically implanted in rats after partial removal of the liver, the numbers of mitoses in the liver were greatly reduced. Further, Fujii and Mizuno[2] demonstrated that this compound has a marked inhibitory effect on the epidermal hyperplasia induced by painting with methylcholanthrene. We attempted to study the influence of the subcutaneous injection of nicotinamide and diphosphopyridine nucleotide (DPN) on the incidence and growth of tumours induced by subcutaneous injection of methylcholanthrene. For this experiment 36 Wistar strain rats weighing about 125 gm. were used. These were divided into three groups, each of which consisted of 12 animals. Rats in each group received subcutaneous injection of 0·25 ml. of cold sterile distilled water (group 1), 1 per cent nicotinamide (supplied by Katayama Chemical Works, Japan) (group 2) or 0·1 per cent DPN (supplied by Nutritional Biochemicals Corp., U.S.A.) (group 3) respectively.

Nicotinamide and DPN were dissolved in cold distilled water. These injections were performed on the back of the rat three times a week until the animals died or were killed. One week after the first injection, all rats were injected subcutaneously in the intrascapular region with 3 mgm. of methylcholanthrene (supplied by L. Light and Co., Ltd., England) in 0·4 ml. of olive oil. The rats of three groups were maintained equally on the usual laboratory diet of whole wheat grains with daily supply of some green vegetables.

During the course of this experiment, all animals showed gradual increase in weight except 3 rats which died of severe pneumonia and lung abscess without any tumour within 100 days after injection of methylcholanthrene. The remaining 33 rats survived more than 100 days after the injection of methylcholanthrene, receiving more than 47 injections of water, nicotinamide or DPN.

Tumour nodules could be first palpated 92 days after injection of methylcholanthrene at the site of injection, and 145 days after injection almost all animals showed tumour nodules. Twenty-three of the tumour-bearing animals died within 167 days; the remaining 10 animals were killed on the 168th day after the injection of methylcholanthrene. The time of '50 and 100 per cent tumour incidence' in each group was as follows: 101st and 120th day in group 1, 122nd and 168th day in group 2, and 124th and over 168th day in group 3. Furthermore, the tumour-incidence rate in groups 2 and 3 was still 30 and 36 per cent respectively, even when that in group 1 reached 100 per cent. From these results, it may be said that the incidence of methylcholanthrene sarcomas was retarded by 3–6 weeks in the groups of nicotinamide or DPN injection, compared with the group of water injection. Average values of tumour weight and tumour index in each group were as follows: 48·1 gm. and 28·1 in group 1, 34·9 gm. and 17·8 in group 2, and 27·6 gm. and 15·7 in group 3. These results denote that nicotinamide and DPN both retarded the growth of tumours. All these tumours were fibrosarcoma, and no difference was observed in histological structure among the groups. That the presence of nicotinamide greatly inhibited cozymase nucleosidase activity in rat brain has been reported by Mann and Quastel[3]. Therefore, it may be probable that nicotinamide injection causes an accumulation of DPN in the cytoplasm, and so exerts its influence by inhibiting the cell division. However, the possibility that nicotinamide enhances the rate of nuclear DPN synthesis and increase of nuclear DPN content results in inhibition of cell division cannot be excluded, since it is expected that nicotinamide serves as a precursor of nicotinamide mononucleotide which is essential for the synthesis of DPN[4]. Thus, the inhibiting effect of nicotinamide and DPN on the incidence and growth of the methylcholanthrene sarcoma observed in the present work may be attributed to such an inhibitory effect on cell division.

Our thanks are due to Prof. I. Hirono and Dr. S. Iwase, Nagoya University, for their encouragement and advice. This work was supported in part by a research grant from the Ministry of Education and the Japan Cancer Society.

Lipofuscin Pigmentation of Sheep Livers in Australia

ALMOST all sheep, as well as some other animals, grazing in certain districts of Australia, develop a peculiar pigmentation of their livers, portal lymph nodes and to a lesser degree of their lungs, without showing any adverse clinical signs. In the Brisbane abattoir about 25,000 livers (3 per cent) are condemned annually because of this discoloration. The pigmented livers are also seen in the Sydney abattoir, but are completely unknown in Tasmania, South Australia, Victoria and Western Australia, according to information obtained from the chief veterinary officers of these States.

According to observations by veterinary officers, graziers, drovers and other people dealing with animals, the pigmentation is found in all sheep grazing in certain areas of mulga (*Acacia aneura*) country. No such evidence has been encountered outside mulga country, but as stated above, this condition does not occur in Western Australia, South Australia or the Northern Territory, although they contain considerable areas of mulga country.

Local people claim to have noticed the discoloration in the livers of sheep, slaughtered as early as two or three weeks after arrival in this particular type of country, while other sheep, which came with the same group but were slaughtered earlier, had normal 'red' livers. The circumstances in which this pigmentation occurs points very strongly towards a nutritional origin. However, it is not known what constituent of the diet is responsible for the change.

Mulga forms extensive forests, in country between the 8–20 in. annual isohytes. It is one of the most important fodder trees in Queensland, being usually 5–8 m., but sometimes up to 12 m., high. In periods of drought trees or branches are cut down and sheep may be maintained on the leaves for years.

On superficial examination all parts of the affected livers are of uniform colour, which may range from a slight darkening to a deep charcoal grey. Closer inspection of the dark livers reveals a brown to black lace-like network, outlining the liver lobules of peripheral and cut surfaces. Histological examination shows pale yellow to dark brown granules, about

2 microns in diameter, mainly in the liver cells. In the darker livers they are also in the Kupffer cells, in phagocytic cells of the portal tracts and in the lumen of central veins and to a lesser degree in the vessels of the portal tracts.

This pigmentation is usually referred to as 'melanosis', because the pigment has the general microscopic appearance of melanin. However, the condition is different from genuine melanosis, a congenital abnormality, seen occasionally in liver and other organs of slaughtered animals[1]. The microscopic distribution of the pigment is also most unusual for melanin; consequently a full investigation of the nature of this pigment was carried out, and the detailed results will be published in monograph form[2].

Numerous reactions were tried and performed simultaneously on liver tissues and on identically treated control material of skin from a black dog, eyes from sheep and bovine hearts with extensive lipofuscin pigmentation. The reactions shown in Table 1 proved particularly useful for differentiating between lipofuscin and melanin.

(1) *Staining with neutral red, gentian violet and Mallory's hæmofuscin method.* The granules in liver and heart were stained to various degrees, while the melanin in skin and eye was not stained. With Mallory's hæmofuscin method the number of visible granules in the liver was increased due to stained precursors.

(2) *Buffered staining with methylene blue, without and after blocking by benzoylation and methylation.* Only three *p*H values are given in Table 1 although 17 were used, ranging from 9·20 to 2·31.

This reaction separated the pigments distinctly in two groups. Without previous blocking, the granules in liver and heart showed strong affinity to methylene blue in alkaline solution, which lessened with decreasing *p*H. In contrast, the melanin granules stained almost uniformly throughout the *p*H range, and the lowest *p*H even increased their affinity to the dye. Benzoylation reduced noticeably the staining of lipofuscin, but intensified that of melanin. Methylation had the same effect to a much higher degree.

(3) *Staining with basic dyes after bleaching, particularly with Nile blue, gentian violet, basic fuchsin, Giemsa and methylene blue.* In unbleached sections all pigments showed affinity to the above dyes. When the tissues were bleached in a mixture of hydrogen peroxide and alkali, the liver and heart granules reappeared on staining, even when they had been exposed to the bleaching agent for a considerably longer time than necessary for complete bleaching of the pigment. The melanin granules had lost their affinity to the basic dye even before they had been completely bleached.

(4) *Fat stains with Sudan IV, oil red 0, and particularly Sudan black.* The granules in liver and heart were stained with the above dyes in increasing intensity, whereby the paler granules showed a stronger reaction than the darker ones. The melanin granules remained unstained.

(5) *The ferric ferricyanide reduction test after treatment with chromic acid and the Bielschowsky silver reaction.* The ferric ferricyanide reduction test was positive with all pigments. However, when the slides were previously treated with chromic acid it was noticed that the liver and heart granules gave a negative reaction, while melanin was still positive. The Bielschowsky silver reaction differentiated between lipofuscin in the heart, which was not or only slightly darkened, and the melanin granules, which showed distinct blackening. In the liver the light granules remained unaltered, while the dark ones were moderately darkened.

(6) *The periodic, performic and peracetic acid–Schiff reactions.* These reactions were positive to various degrees with the pigment in liver and heart, but negative or almost negative with melanin.

(7) *Bleaching with hydrogen peroxide.* Not only speed of bleaching but particularly the difference between formalin- and alcohol-fixed material was observed. It was noticed, first, that lipofuscin was more resistant to bleaching than melanin. This is a generally recognized technique of distinguishing between lipofuscin and melanin. Secondly, it was observed that lipofuscin bleached more quickly in alcohol than in formalin-fixed tissue, while the reverse was the case with melanin. The pigment in the liver acted like lipofuscin.

As a result of these reactions it has been concluded that the pigment in the livers is lipofuscin at various stages of oxidation, ranging from unstained precursors, which can be made visible by certain reactions, to dark brown and very inert granules, which may be difficult to distinguish from melanin. A number of the techniques used represent an advance in methods of differentiating lipofuscin and melanin.

RADIOBIOLOGY

Accidental Radioactive Labelling of a Migratory Moth

Radioactive labelling from the Sahara atomic bomb tests (*by* H. B. D. K.). It has been shown in the laboratory that if the larvæ of Lepidoptera are fed on radioactive foliage for a 24-hr. period, the resulting radioactive imagines can be readily identified. Furthermore, for such an isotope as sulphur-35, the count may actually be higher in the imago than it was in the larva. This is due to the increased surface area of the wings[1]. More recently, this method has been put to the test in wild populations[2]. Homometabolous insects, and in particular the Lepidoptera, are in fact ideally suited to this type of labelling.

In February 1960, it was reported that the first of two atomic weapons had been exploded successfully in North Africa. It appeared to me that this might offer an opportunity for the first time of checking whether certain migratory moths, which arrive in Great Britain in the early months of the year, had flown direct from the African Continent. It has not hitherto been possible to show by any experimental devices whether certain species that have their breeding reservoirs in the North African deserts do in fact spread northwards from Africa each year throughout Europe. Accordingly, a notice was placed in many British and Continental entomological journals requesting early migratory specimens of seven species suspected by me of maintaining their winter populations in North Africa but not in Europe.

Of the several hundred specimens received (the majority were the Noctuid moth, *Plusia gamma* L.), one insect only was found to have an increased count under the Geiger-counter. This was a specimen of *Nomophila noctuella* L. (Fig. 1) taken by me in a mercury-vapour trap at Steeple Barton, Oxford, on the morning of March 10. This insect, which was a pale buff colour, unlike the home-bred specimens which occur in the late summer, was one of four taken in Britain about the same date. It consistently gave a count of 15–20 per cent above background. The specimen was therefore subjected to autoradiography for three months, at the end of which time the X-ray films were developed. Because of the increased count, it was anticipated that a larva of this quick-feeding species might have fed on contaminated vegetation and that the resulting imago would show the usual autoradiograph of an individual so treated. The X-ray films, however, showed no such thing, but a single spot of very small size was visible. In view of this, and at the request of the Health Physics Division, Atomic Energy Research Establishment, Harwell, the insect, along with the autoradiographs, was passed over to them, and their findings are reported here. During the earlier investigations, a specimen of *N. noctuella* taken in 1892 was used as a control. It gave negative results throughout.

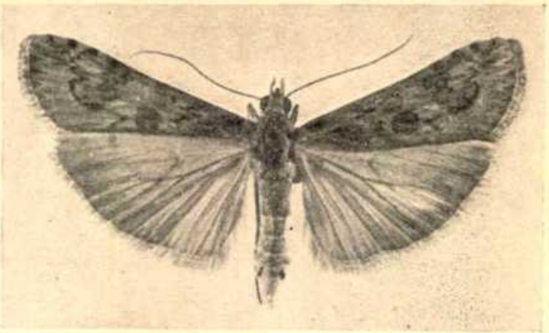

Fig. 1. (× 2½)

Report on the radioactive moth Nomophila noctuella L. (*by* M. J. H.). The appearance of the initial autoradiograph suggested a point source of βγ-activity close to the surface of the thorax of the moth. Subsequent autoradiographs of preparations of this part of the moth resulted in the identification of a single radioactive particle (Fig. 2). This particle is a perfect sphere, 9μ in diameter and of a dark brown colour. It is entirely typical of the particles observed after test explosions on, or near, the surface of the ground and is probably composed of fused silica coloured by traces of metal.

As there had been a long gap in the testing of nuclear devices before February 1960, a particle of this size could not have originated from earlier explosions. Its origin in the Sahara test of February 13 is confirmed by the pattern of its radioactive decay. Several estimates of the disintegration-rate were made using an end-window counter initially, and the size of autoradiograph images later. The decay of mixed fission products is normally expressed in the form $A \propto T^{-n}$, where n is a constant. The scatter of measurements, which involved several different detection systems, is considerable. However, assuming the time of origin to be February 13, the value of n for this particle falls within the range 1·0–1·5. This agrees with observations of the decay of individual fall-out particles. The actual activity of this particle on March 18 was 7 μμc. (beta).

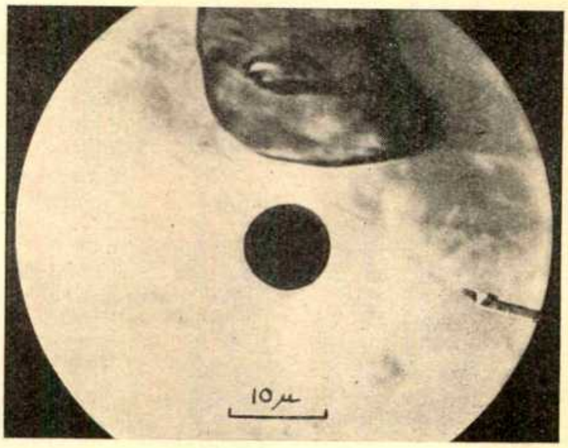

Fig. 2

The value to migratory problems of the evidence from this moth depends on where it picked up the particle—in Africa or in more northerly latitudes. Meteorological data suggest that the main radioactive cloud travelled eastward in a fairly narrow cone. Rises in levels of activity observed in western Europe indicate arrival of the cloud at the end of February (26–29) after the first global circuit. At this age, it is unlikely that 9-μ particles would still be present. A possibility would be of a small, highly active particle, airborne for two weeks, and afterwards attached to a 9-μ particle of natural dust. This could have happened anywhere over Europe. However, the particle observed was not a resolvable aggregate and, as stated above, was typical of particles originating in the high temperature of the explosion. There is also the possibility of pockets of contaminated tropical air passing over southern Europe and depositing radioactive particles in the period immediately after the explosion. We have no definite evidence to support this beyond a slight rise in southern Italy on February 22–23. However, even if this did occur, large particles such as that on this *N. noctuella* would be very rare, whereas they could be quite abundant in the area of immediate deposition in the Sahara. I believe, therefore, that there must be a very strong probability that this moth acquired its radioactive particle before leaving Africa on its journey northward.

Conclusions. The evidence provided suggests, but not conclusively, that insects as small as the moth *N. noctuella* can cover a distance of approximately 1,500 miles in the course of their short lives.

Influence of Hypothermia on the Survival of Mice after Large Doses of X-Radiation

It is known that hypothermia applied after irradiation prolongs the survival of frogs[1,2] and hibernating animals[3], and slows down destructive processes in the hæmatopoietic tissue and blood[3,4]. In our previous work we showed that prolonged hypothermia at 22–25° C., lasting 6–48 hr., after irradiation also slows down destructive changes in the blood, spleen and bone marrow[5,6]. After the ending of hypothermia and reaching the normal body temperature these changes, however, develop even more intensely than in controls subjected to irradiation only and the mean survival-time is shorter. After doses up to 15,000 r. animals survive for more than 3 days after irradiation[7] and do not tolerate such prolonged hypothermia. Therefore investigations of the survival-time after irradiation in homoiothermic animals under hypothermia can be carried out only after large doses of irradiation where the control animals die a few hours following irradiation, which is a well-tolerated duration of hypothermia.

In our experiments white male mice were used weighing 20–25 gm., which were divided into four groups: irradiated controls without hypothermia (Table 1, V), mice with intraperitoneal injections of 'Largactil' and 'Phénergan' ('Specia') solutions at 0·2 mgm./10 gm. body-weight which were subjected immediately after irradiation to hypothermia, that is, a body temperature of 20–24° C. measured by thermocouple in the rectum (Table 1, III, VII—artificial hypothermia), mice subjected to hypothermia in ice without the lytic mixture and maintained up to death at a body temperature of 20–24° C. (Table 1, IV, VIII—hypothermia) and finally mice with luminal sodium anæsthesia (Table 1, II) and thiopentone sodium anæsthesia (Table 1, VI). We irradiated four mice at a time, one from each group, in a plexit box on a turning-table (two rotations per min.) which ensures homogeneity and uniform X-ray dosage. Mice of groups I–IV were subjected to whole-body irradiation with 40,000 r., groups V–VIII 45,000 r. (180 kV., 15 m.amp., without filter, target distance 16 cm., dose-rate 1,000 r./min.).

Table 1. STATISTICAL EVALUATION AS COMPARED WITH CONTROLS

Group	No. of animals	Mean survival time (hr.)	Minimum and maximum survival time (hr.)
	40,000 r.		
I Control	24	2·02 ± 0·18	0·35– 3·85
II Luminal sodium $t = 27$–$30°$ C.	20	3·72 ± 0·31 $P = 0·001$	1·20–6·30
III Artificial hypothermia $t = 20$–$24°$ C.	20	6·57 ± 0·55 $P < 0·001$	1·25–12·35
IV Hypothermia $t = 20$–$24°$ C.	24	6·06 ± 0·57 $P < 0·001$	0·90–13·35
	45,000 r.		
V Control	15	1·29 ± 0·15	0·60–2·50
VI Sodium thiopentone $t = 34$–$35°$ C.	17	1·10 ± 0·11 not significant	0·35–1·95
VII Artificial hypothermia $t = 20$–$24°$ C.	15	3·87 ± 0·37 $P < 0·001$	1·65–7·50
VIII Hypothermia $t = 20$–$24°$ C.	17	3·60 ± 0·47 $P < 0·001$	1·15–7·20

In a special experiment we confirmed the finding[7] that the mean survival-time of mice exposed to doses of 15,000–50,000 r. decreases exponentially with the rising dose of irradiation and is thus a suitable criterion for our experiments.

The mean survival-time of mice after irradiation is recorded in Table 1. Hypothermia prolongs with statistical significance the mean survival-time of animals and reduces the effective dose of radiation from 40,000 r. to about 35,000 r. and from 45,000 r. to about 38,000 r. This effect can be ascribed to two mechanisms: hypothermia which slows down the development of pathophysiological processes after irradiation and the associated inhibition of the central nervous system which leads to a mitigation of symptoms described in the literature after these large doses of irradiation, to a reduction of the hyperexcitability and to a delay of the convulsive state. The inhibitory effect of hypothermia of 20–24° C. corresponded approximately to the effect of thiopentone, after which we did not record an increase in the survival time. Sodium luminal anæsthesia had a protective effect, but reduced at the same time the body temperature to 27–30° C., and therefore we cannot ascribe the longer period of survival entirely to the inhibition of the central nervous system. It is more probable that the main part is played by hypothermia and the associated inhibition of the central nervous system enhances the protective effect. This may explain also the somewhat more favourable results obtained with hypothermia when combined with the administration of the lytic mixture than with hypothermia alone.

Theoretical Considerations in the Ultra-violet Irradiation of Micro-organisms

Morowitz[1] has derived equations relating survival ratio (N/N_0) for a given species of micro-organism to the ultra-violet quantum density (B_0) at the surface of an irradiated volume of liquid of absorbance α and uniform depth L. For a micro-organism of 'target area' S, the equation for a perfectly mixed volume of liquid is:

$$\frac{N}{N_0} = e^{-SB_0 \frac{1 - e^{-aL}}{aL}} \qquad (1)$$

and for a stratified, or completely unmixed liquid:

$$\frac{N}{N_0} = \frac{1}{\alpha L} \int_{SB_0 e^{-aL}}^{SB_0} \frac{e^{-u}}{u} \, \mathrm{d}u \qquad (2)$$

For experiments with thin films of liquid supported on polished aluminium or other highly reflective surfaces, I have found it necessary to modify the Morowitz equations to allow for the contribution of light which is reflected back into the liquid. When the reflectance of the supporting surface is R, equation 1 becomes:

$$\frac{N}{N_0} = e^{-SB_0 \frac{1 - e^{-aL} + Re^{-2aL}(e^{aL} - 1)}{aL}} \qquad (3)$$

and equation 2 becomes:

$$\frac{N}{N_0} = \frac{1}{\alpha L} \int_{e^{-aL}}^{1} \frac{e^{-SB_0\left(u + \frac{Re^{-2aL}}{u}\right)}}{u} \, \mathrm{d}u \qquad (4)$$

For films of liquid thin enough or transparent enough, the degree of mixing is theoretically unimportant, since equations 3 and 4 (as well as 1 and 2) converge for very low values of αL. To determine the limiting values of film transmittance (e^{-aL}) above which mixing may be ignored as a variable, I computed the deviation between equations 3 and 4 for $0 < e^{-aL} < 1$ and $0 < R < 1$, using the IBM 650 computer with the assistance of Mr. John H. Witmer. For survival ratios down to 10^{-6}, the calculated deviation was found to be less than 12·6 per cent (one-tenth of a logarithmic unit of infectivity) when film transmittance was above the limiting values shown in Table 1. This deviation is negligible in comparison with the usual errors in measuring microbiological activity.

Table 1. Values of Film Transmittance (e^{-aL}) above which Mixing of the Liquid during Irradiation does not Appreciably influence the Predicted survival Ratio

R	e^{-aL}	R	e^{-aL}
0	0·84	0·5	0·69
0·1	0·81	0·6	0·66
0·2	0·78	0·7	0·63
0·3	0·75	0·8	0·60
0·4	0·72	0·9	0·57

For film transmittances greater than the limiting values, therefore, mixing of the liquid during irradiation seems to be unnecessary, and equation 3 adequately describes the predicted course of inactivation whether the liquid is mixed or not.

BIOLOGY

Water-Conduction in the Stems of Certain Conifers

In a laboratory study of the rate of flow of water through sapwood samples of *Pseudotsuga taxifolia* (Poir.) Britt., *Pinus nigra* Arnold, and *P. radiata* D. Don., the effective water-conducting areas were determined by using aqueous solutions of various dyes. It was observed that water-flow in the direction of the grain was restricted to the early wood, and that the late wood only became coloured, if at all, by later diffusion of dye, especially along wood rays. When acid fuchsin was used the wood became almost uniformly coloured due to the ready diffusion of this dye across the late wood, but when safranin was used the late wood remained unstained.

The late wood of all three species appeared to be drier than the early wood, and showed up as lighter coloured streaks on the radial longitudinal surfaces of fresh sapwood. To examine this condition in detail, radial strips of wood, 1 cm. square, cut from freshly felled trees, were dissected into early wood and late wood samples and weighed immediately after dissection. Though complete separation was difficult, the early wood proved to be 95 per cent saturated with water, whereas the late wood, apart from the outermost growth layer, was only 65–70 per cent saturated.

Safranin dye injected into living trees was also shown to move along the early wood, the late wood only becoming stained some distance behind the limits of dye movement. As in the laboratory experiments, acid fuchsin passed into the late wood so rapidly that the effect was less apparent.

These phenomena have been observed from June (mid-winter) until February, and, although resin-flow in the two pines interfered with dye-injection experiments during the spring, laboratory studies of water-flow and percentage saturation gave similar results at all times.

In the coniferous species examined, it therefore appears that the late wood is not an effective water-conducting tissue owing to its low degree of saturation with water. It is possible that the structure of the bordered pits in late wood prevents effective aspiration when an air bubble forms in a tracheid, so that the conducting columns soon break down. Whatever the cause, the implications are of interest when considering water conduction in the living stems, and also for wood preservation by diffusion processes.

In a previous communication[1], it was suggested that the percentage of pits aspirated in the early wood of the inner sapwood was related to the degree of saturation of the wood with water. But, as the percentage saturation was determined for the late wood and early wood together, it is obvious from the present work that this was a chance relationship, and some other cause must be sought to explain the progressive aspiration of bordered pits from the outer to the inner sapwood.

Finally, in considering water-flow in these trees, it seems that we must recognize the possibility that continuity between the transpiring leaves and the roots is only possible along those growth-layers penetrated by the traces of living needles. Growth-layers interior to these are isolated by non-conducting bands of late wood, and although these are crossed by ray tracheids, observations of the flow of dye through radial sections of the stem have shown that the dye moves on a broad front, and does not pass more freely along rows of ray tracheids than it does along the ray parenchyma. This apparent discontinuity of the late wood therefore implies that, in the inner sapwood, the movement of water by cohesion takes place along a series of separate concentric paths bridged only by the osmotic forces in the living cells of wood rays.

It is intended to publish these results in greater detail elsewhere.

Phenomic Delay in Transduction of *Salmonella typhimurium* Cell

Transduction has been demonstrated in the genus *Salmonella* by Zinder and Lederberg[1]. The individual markers were induced independently of each other according to the selective medium used. Even in cultivation conditions with two sugars, invariably only one of them was fermented by the individual transduced colonies.

In my experiments I studied the mechanism of transduction of galactose fermentation. Basically, I wanted to determine whether the given substrate acts only as a selection factor in transduction, or participates also in the mechanism of transduction. I used strains of *Salmonella typhimurium*, LT_2 (Fen+, Ty+, Tr+; Gal+, Xyl+) and SW_{351} (Fen−, Ty−, Tr−; Gal−, Xyl−), described by Zinder and Lederberg[1] and kindly sent to me by them. A constitutive galactozymase enzymatic system was found. Also, the transduction occurs even without the presence of a specific substrate. It was found, however, that the transduced cells multiply either very slowly under these experimental conditions without the galactose or do not multiply at all.

I tried, therefore, in further experiments to find out whether the presence of this fairly high number of recipient cells (about 10^9) has no inhibitory effect on the growth of newly started transduced cells. Table 1 shows the results of a typical dilution experiment[2]. The suspension of the known number of cells, obtained by washing a 48-hr. SW_{351} strain cultured on complete agar[3], was mixed with the filtrate of the transducing phage in ratio 1 : 1 and exposed for 30 min. at 37° C. The cell suspension with the adsorbed phage particles was then successively diluted with the complete medium and always two eosin methylene blue agars from each dilution were inoculated either without or with a 1 per cent solution of galactose. The number of colonies fermenting galactose on the eosin methylene blue agars with the galactose indicates the number of inoculated cells with the adsorbed phage. After 24- or 48-hr. growth the film of bacteria from the eosin methylene blue agars without the galactose was washed off in saline, the suspension was diluted to 2 ml. and the total number of cells as well as the number of transduced galactose-fermenting cells were determined. The number of cell-divisions in the culture was estimated from the amount of recipient cells inoculated on the eosin methylene blue agar without galactose and the number of cells grown after 24 or 48 hr. (ref. 4). I determined then, in the same way, the number of divisions of transduced cells from the amount of galactose-fermenting cells on eosin methylene blue agars inoculated with a diluted mixture of cells and phage particles, and from the amount of galactose-fermenting colonies after 24 or 48 hr. growth.

Table 1 indicates that the increased number of divisions of all cells is also connected with a higher number of divisions of the transduced cells. It can, therefore, be concluded that no specific substrate, which acts only as a selection factor, is needed for the transduction. Under the given experimental conditions, that is, without the selection factor and in the presence of a great number of inoculated cells, the growth of the transduced cells is inhibited.

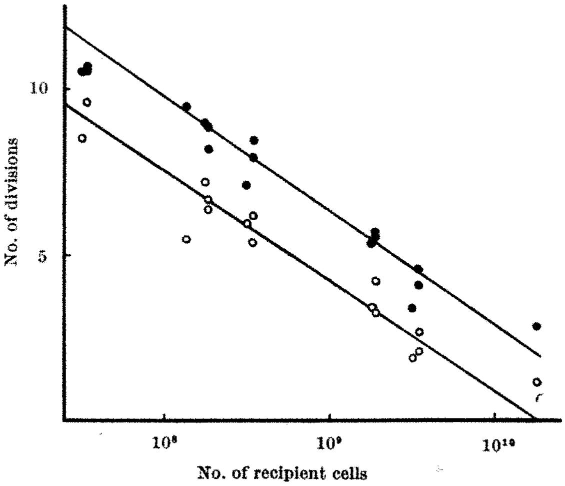

Fig. 1. The number of divisions of recipient (—●—) and transduced (—○—) cells

Table 1. INFLUENCE OF INITIAL NUMBER OF CELLS PLATED ON THE GROWTH OF THE RECIPIENT AND TRANSDUCED CELLS

Exp. No.	No. of cells		No. of divisions	No. of inoculated cells capable of transduction	No. of Gal + cells after growth*	No. of divisions of Gal + cells	No. of Gal + cells to colony
	inoculated	after growth*					
1	$2\cdot5 \times 10^{10}$	$1\cdot94 \times 10^{11}$	2·9	252	600	1·2	2·3
	$5\cdot0 \times 10^{9}$	$5\cdot2 \times 10^{10}$	3·4	237	880	1·9	3·7
	$2\cdot5 \times 10^{9}$	$9\cdot8 \times 10^{10}$	5·3	116	1,200	3·4	10·3
	$5\cdot0 \times 10^{8}$	$6\cdot8 \times 10^{10}$	7·1	26	1,700	6·0	65·4
	$2\cdot5 \times 10^{8}$	$1\cdot2 \times 10^{11}$	9·0	14	2,080	7·2	145·0
	$5\cdot0 \times 10^{7}$	$7\cdot2 \times 10^{10}$	10·5	2	700	8·5	350·0
2	$5\cdot4 \times 10^{9}$	$1\cdot3 \times 10^{11}$	4·6	212	920	2·1	4·3
	$2\cdot7 \times 10^{9}$	$1\cdot4 \times 10^{11}$	5·7	106	1,880	4·2	17·7
	$5\cdot4 \times 10^{8}$	$1\cdot4 \times 10^{11}$	8·0	21	900	5·4	42·8
	$2\cdot7 \times 10^{8}$	$1\cdot2 \times 10^{11}$	8·9	10	860	6·4	86·0
	$1\cdot3 \times 10^{8}$	$9\cdot6 \times 10^{10}$	9·5	5	220	5·5	44·0
	$5\cdot4 \times 10^{7}$	$8\cdot8 \times 10^{10}$	10·6	2	1,600	9·6	800·0

* 24-hr. and 48-hr. growth for experiments 1 and 2 respectively.

Table 1 shows further that the number of divisions of transduced cells has on an average two divisions less than the number of divisions of all recipient cells (Fig. 1).

I studied, therefore, this phase of the delayed phenotypic expression[5] to find out whether the problem in question is a matter of change of the genotype (changes in the deoxyribonucleic acid (DNA)), or of the phenotype expression of the changed genotype (synthesis of certain building blocks of new enzymes). Chloramphenicol was used as the inhibitor of the proteosynthesis. This does not inhibit the synthesis of the genetically functioning DNA. The cell suspension with the adsorbed phage was diluted at a ratio of 1 : 50 by a complete medium and cultivated for 6 hr. at 37° C. Chloramphenicol (final concentration 20 μgm./ml.) was added at 0, 2, 4 and 6 hr. cultivation and afterwards the cells were centrifuged and washed twice with saline. Thereafter the number of generations of recipient and transduced cells was determined as in previous experiments. The results are given in Table 2.

Table 2. INFLUENCE OF CHLORAMPHENICOL ON THE PHASE OF THE DELAYED PHENOTYPIC EXPRESSION

Cultivation at 37° C. (hr.)	Choramphenicol added after hr. of growth	No. of divisions before adding chloramphenicol	No. of divisions of recipient cells (*a*)	No. of divisions of transduced cells (*b*)	Difference in division (*a*−*b*)
—*	—	0	11·5 ; 11·3	8·1 ; 7·3	3·7
6	0	0	12·5 ; 12·2	11·4 ; 10·5	1·4
6	2	1·2	11·4 ; 11·9	10·7 ; 10·4	1·1
6	4	5·5	7·6 ; 6·8	7·8 ; 6·7	0
6	6	5·8	7·3 ; 7·0	6·8 ; 6·8	0·3

* Control sample without chloramphenicol and without cell division.

It was found that a complete compensation of the number of recipient and transduced cells occurs after the fourth hour of cultivation in the complete medium without chloramphenicol, where the five generations occur. The presence of chloramphenicol shortens the phase of delayed phenotypic expression, that is, certain processes are accomplished which are not inhibited by chloramphenicol and are part of the changes of genotype of the recipient cell. At the same time, even with the presence of chloramphenicol, there is a certain delay in the number of generations, which is the growth and proteosynthetic phase, inhibited by chloramphenicol, and part of the expression of phenotype.

The problem of the phase of the delayed phenotypic expression will be subjected to further biochemical examination.

I wish to express my appreciation to Academician I. Málek for his valuable suggestions and encouragement.

Acquisition of Graft versus Host Tolerance

RECENTLY, Simonsen[1] and Siskind, Leonard and Thomas[2] have reported attempts to produce 'runt disease' in neo-natal mice by the passage of the cellular chimera established in lymphoid organs of infant mice following the injection of spleen cells obtained from adult mice. As Simonsen and Jensen[3] had previously noted that splenic enlargement was a regular and early symptom in affected animals, this phenomenon was used by Simonsen to assess the graft-versus-host response. He concluded that the chimeric cells fail to produce runt disease on passage. This finding appears to conflict with the results described by Siskind and his colleagues, who observed that infant recipients of the appropriate strain not only showed similar symptoms on passage of the chimeric cells, but also that the runt syndrome observed in the passage animals was symptomatically more severe. The analysis of the runt syndrome carried out in this Laboratory supports and extends the findings described by Simonsen.

My work has generally been confined to the production of the runt syndrome in mice following the intravenous injection of *C57B*1 adult spleen cells into *C3H* neo-nates (within 24 hr. of birth), and the reciprocal situation which is obtained when *C3H* adult spleen cells are injected into *C57B*1 neo-nates. When 10 × 10^6 or more adult *C57B*1 spleen cells are injected intravenously into *C3H* neo-nates, all recipients become acutely affected and die within three weeks of injection. The injection of 10 × 10^6 *C3H* adult spleen cells into *C57B*1 infants produces the less-severe symptoms of chronic runt disease, with about 50 per cent of the injected animals surviving two or more months. Passage was made by removal of spleens from the affected mice 6–21 days after inoculation. Usually 10 × 10^6 dissociated cells were passaged intravenously in neo-nates. In these passage experiments runting occurred in only a small proportion of mice or was completely absent. Tests for chimeric cells were made at the time of passage

Table 1. INCIDENCE OF RUNTING AND CHIMERISM ON PASSAGE OF SPLEEN CELLS OBTAINED FROM ACUTE AND CHRONIC RUNTS

System	Passage	Percentage runting	Chimerism (chimeric cells detected in X nucleated spleen cells)
(1) Spleen cells obtained from normal donors.			
(*a*) *C57* adult spleen cells injected into *C3H* neo-nates	Primary induction	100 (11/11)	$X = 20 \times 10^6$
	1st passage	25 (2/8)	$X = 20 \times 10^6$
	2nd ,,	0 (0/8)	$X = 20 \times 10^6$
(*b*) *C3H* adult spleen cells injected into *C57B*1 neo-nates	Primary induction	100 (39/39)	Not tested
	1st passage	0 (0/40)	$X = 20 \times 10^6$
(2) Spleen cells obtained from immunized donors			
(*a*) Pre-sensitization by skin graft of recipient strain. *C3H* adult spleen cells injected into *C57B*1 neo-nates	Primary induction	100 (22/22)	*c.* 10 per cent n.c.* chimeric
	1st passage	60 (8/13)	*c.* 5 per cent n.c.* chimeric
	2nd ,,	0 (0/15)	*c.* 5 per cent n.c.* chimeric
(*b*) Pre-immunization by injection of donors with recipient strain spleen cells. *C3H* adult spleen cells injected into *C57B*1 neo-nates	Primary induction	100 (30/30)	$X = 10 \times 10^6$
	1st passage	0 (0/18)	$X = 10 \times 10^6$

* Percentage of nucleated spleen cells estimated by titration of the chimera to be of donor strain origin.

using Billingham and Brent's[4] technique, in which the presence of donor-type cells is shown by the accelerated rejection of a donor skin graft in 10-week mice inoculated 7 days previously with the spleen cells in question. In some experiments graded doses were used in an attempt to assess the proportion of skin cells.

Tests for chimeric cells were also made on spleens obtained from the unaffected first or second passage recipients (Table 1). These experiments demonstrate the persistence in the passage animals of chimeric cells which fail to elaborate a response against the host. It is reasonable to conclude, therefore, that the chimeric cells have become tolerant of host antigens during passage. This conclusion is confirmed and extended by work on the passage of spleen cells obtained from donor mice which were immunized with recipient strain spleen cells, and donors which had been pre-sensitized with an orthotopic skin graft of the recipient strain. Again the incidence of runt disease was either greatly reduced on the first passage and absent on second passage, or the infant recipients completely failed to show any signs on first passage of the chimeric cells. The presence of the chimeric donor cells was again detected in the spleens of the normal passage animals (Table 1).

On several occasions evidence of casual infection, presumably by a virus, was obtained on passage of spleen and liver obtained from chronic runts six weeks following injection of homologous spleen cells. This was not seen when neo-nates were injected with isologous spleen cells obtained from normal adult mice. The presumed virus produces a progressive and fatal disease in infant mice which closely resembles acute runt disease. It produces no symptoms in adult mice. Histologically, gross destruction of liver cells is seen in the affected mice. The cellular infiltration observed in the virus-infected livers is polymorphonuclear in nature. The liver lesion produced by the virus may therefore be readily distinguished from the liver lesion produced in immunologically affected animals by graft-versus-host reaction, as this latter lesion is characteristically associated with a lymphocytic infiltration. It is probable that latent colony infections ultimately bring about the death of the debilitated chronic runts, and consequently passage of organs of such animals is liable to contamination of the cell chimeras with latent infection.

A fuller account of this work will be given elsewhere.

These investigations have been supported in part by a C. J. Martin fellowship during tenure in the Department of Zoology, University College, London, and by a grant made available by the National Health and Medical Research Council, Canberra, A.C.T.

Adipokinetic Activity of Synthetic Peptides Related to Corticotropin

SYNTHETIC peptides prepared by Hofmann and associates[1] containing 8, 10 or 13 amino-acids identical in sequence with the N-terminal portion of corticotropin were tested for adipokinetic activity because corticotropin was known to have this activity[2–4]. The tridecapeptides caused the release of free fatty acids by adipose tissue; the decapeptides were also active but less potent, but the octapeptide had no effect in the amounts tested.

The synthetic peptides were:

	N-terminal	1	2	3	4	5	6	7	8	9	10	11	12	13
I		ser	tyr	ser	met	gluta	his	phe	arg					
II	N-acetyl	ser	tyr	ser	met	gluta	his	phe	arg	try	gly			
III		ser	tyr	ser	met	glu	his	phe	arg	try	gly			
IV	N-acetyl	ser	tyr	ser	met	gluta	his	phe	arg	try	gly	lys	pro	valamide.
V		ser	tyr	ser	met	glu	his	phe	arg	try	gly	N-formyl lys	pro	valamide.

For comparison, the structure of the amino-terminal portion of corticotropin and the total structure of α-melanocyte-stimulating hormone are presented:

		1	2	3	4	5	6	7	8	9	10	11	12	13	
ACTH		ser	tyr	ser	met	glu	his	phe	arg	try	gly	lys	pro	val	. . . 39.
α-MSH	N-acetyl	ser	tyr	ser	met	glu	his	phe	arg	try	gly	lys	pro	valamide	

ACTH, Adrenocorticotrophic hormone; MSH, melanocyte-stimulating hormone

When added to rat epididymal adipose tissue incubated in 1·0 ml. Krebs–Ringer phosphate–5 per cent defatted albumin, 10 μgm. of IV or V stimulated the production of free fatty acids (Table 1). A smaller but significant response was seen with 1 μgm. II was active at a dose of 100 μgm., III was probably active at that dose, and I was inactive. The minimal effective dose of corticotropin is about 0·001 μgm.[4].

In contrast to the weak effect of the peptides relative to corticotropin on rat tissue, the potency of IV and of V was similar to that of corticotropin

Table 1. Effect of peptides on production of free fatty acids by pieces of rat epididymal adipose tissue (approximately 100 mgm.) in 1·0 ml. Krebs–Ringer phosphate–5 per cent albumin, *p*H 7·4, incubated in Dubnoff shaker for 3 hr. at 37°. The control and experimental samples of adipose tissue were obtained from the same rats. Medium and tissue were extracted together at end of incubation and titrated

Test substance	No. of samples	Dose (μgm./ml.)	Free fatty acid after incubation (μequiv./gm./hr.)	*S.E.*	*P* value
Control	17	—	3·3	0·49	
I	17	100	3·2	0·53	—
Control	17	—	3·1	0·50	
II	17	100	5·8	0·91	≈ 0·01
Control	17	—	3·3	0·51	
III	17	100	4·4	0·57	—*
Control	17	—	2·1	0·33	
IV	17	10	6·1	0·79	< 0·001
Control	17	—	2·1	0·33	
V	17	10	5·3	0·62	< 0·001

* Difference is significant if *P* value calculated from differences of matched pairs. Values presented in Table 1 were obtained from formula

$$t = \frac{\text{difference of means}}{S.D.\text{ of combined groups}} \sqrt{\frac{N_1 N_2}{N_1 + N_2}}$$

Table 2. Free fatty acids after incubation of pieces of rabbit perirenal adipose tissue. Conditions were same as in Table 1. Number of samples in parentheses

Test substance	Free fatty acid (μequiv./gm./hr.) after incubation with indicated dose (μgm./ml.)					
	0	0·01	0·03	0·1	10	30
Control	0·95 (11) ± 0·42 (*S.D.*)	— —	— —	— —	— —	— —
I	—	—	—	—	—	0·71 (8)
II	—	—	—	0·78 (4)	9·3 (4)	
III	—	—	—	—	8·7 (4)	—
IV	—	2·4 (9)	8·0 (4)	10·4 (5)	—	—
V	—	1·5 (5)	4·4 (4)	9·4 (6)	—	—

when tested either on isolated rabbit adipose tissue or in the intact rabbit. The output of fatty acids *in vitro* was increased by 0·01 μgm. of IV, and by 0·03 μgm. of V. II was inactive at 0·1 μgm., but both II and III were strongly active at 10 μgm., while I was inert at 30 μgm. (Table 2). When injected subcutaneously in 2–3 kgm. male rabbits, 10 μgm. of IV or 30 μgm. of V was sufficient to increase severalfold the plasma free fatty acids measured 1½ hr. later. 300 μgm. of II, the largest dose tested, was ineffective (Table 3).

The adipokinetic property of corticotropin is thus first encountered when the amino-terminal octapeptide is elongated to the decapeptide, and the potency increases with the addition of the next three amino-acids. The increased potency of the tridecapeptide was seen both in the rabbit, in which the tridecapeptide was as active as corticotropin, and in the rat in which it was only 1/1,000 as active. N-acetylation of the terminal serine did not lower the adipokinetic activity of the peptides and may have increased it slightly. By comparison, terminal acetylation of corticotropin has been reported to decrease corticotropic activity to less than 10 per cent, while enhancing melanophore-expanding activity[5]. This first demonstration of fat mobilization caused by synthetic peptides may serve as a guide to the structure of compounds controlling this aspect of fat metabolism and may facilitate an analysis of the interrelated structural requirements for adipokinetic, corticotropic and melanophore-expanding activity.

Table 3. Free fatty acids of plasma 1½ hr. after subcutaneous injections of test substance in fed male rabbits weighing 2–3 kgm. Number of tests in parentheses

Test substance	No injection	Negative tests	Plasma free fatty acids (μequiv./l.) after indicated dose (μgm.)					
			3	10	30	100	300	1,000
None	559 (7) ± 153 (*S.D.*)	543 (52) ± 170 (*S.D.*)						
II							495 (3)	
IV			231 (2)	1,839 (4)	2,034 (4)	3,600 (1)	2,280 (1)	3,480 (1)
V				586 (2)	1,041 (2)	1,497 (2)	2,633 (2)	3,420 (1)

Opal in the Animal Body

Recent work on opal-phytoliths[1–4] has led to searches for these microscopic bodies of amorphous silica in the body of a sheep. This is a typically herbivorous animal that ingests significant quantities of silica as integral parts of its plant food.

The food and the rumen contents of a sheep on a diet of oaten hay have been examined both before and after destruction of organic matter[5]. By the destruction of organic matter with nitric and perchloric acids, insoluble residues were obtained which consist largely of opal-phytoliths. Accompanying the opal-phytoliths is a small proportion of other particles including several mineral species, diatom frustules, silicisponge spicules, and fragments and microspheres of artificial substances. These particles are mechanically incorporated with the food and ingested by the sheep; they are more common in the ventral than in the dorsal regions of the rumen. It is proposed to name them allothigenes, and it is intended that this term should include all particles which are generated outside the animal body and which are taken into the body either by ingestion or inhalation.

The amounts of allothigenic material ingested by sheep may be substantial. It is estimated that a total of 10 gm. was present in the rumen of the sheep fed on oaten hay; opal-phytoliths made up 95 per cent of this amount. In some plants, for example *Lolium rigidum*, the content of opal-phytoliths can be twice as high as in oats, and the rumen of a sheep feeding on such plants can be expected to contain 20 gm. of allothigenic material. From examinations of fæcal material it is evident that the allothigenes are inert and that most of them are excreted after passing along the alimentary tract.

The knowledge that substantial quantities of allothigenes are presented to the epithelial surfaces of the alimentary tract led to a search for them in the lymphatic system[6]. The following lymph nodes were taken from slaughtered sheep: prescapular, mediastinal, mesenteric, popliteal, precrural and bronchial. Insoluble residues obtained by digestion with nitric and perchloric acids revealed opal-phytoliths and several mineral species in every node. The presence of these allothigenes was confirmed in sections of prescapular and mesenteric nodes.

The mechanism of entry of allothigenes into the lymphatic system is not known. It is interesting, however, to note that much of the pathway of absorption of particles of fat from the intestinal mucosal surface to the lacteals is extra-cellular. Such a pathway may well hold for the allothigenes. Other factors contributing to their entry would undoubtedly be their size, shape and hardness combined with the various movements of the intestine, such as vascular pulsations, peristalsis, segmentation, and the pumping action of the mucosal villi.

Entry of opal-phytoliths and other minerals into the tissues of the animal subsequent to ingestion has not been recognized before. On the other hand, it is well known that sheep ingest appreciable quantities of soluble silica, most of which is absorbed and finally excreted in the urine. It is less well known that the absorbed silica may be precipitated in various parts of the body to form opal-zooliths. Siliceous uroliths provide an example of this process. This led us to examine specimens obtained from a ram which had died of urolithiasis[8]. X-ray and microscopic techniques showed that the uroliths of this ram were opaline silica, like those found in steers[9]. The most striking fact about the uroliths of the ram was the presence within them of opal-phytoliths. It seems that they sometimes act as nuclei and initiate the precipitation of silica. These allothigenes must have entered the blood stream and finally penetrated the glomerulus. The conclusion that allothigenes can enter the blood-stream is supported by the fact that birefringent allothigenes have been found in the blood and organs other than the lungs of humans, having found their way into the general circulation from the lungs[10].

In view of their inertness, size, shape and hardness it is possible that the allothigenes damage tissues and impair function in more ways than has yet been recognized. Opal-phytoliths are a major cause of wear in teeth[11], and they affect the depth of the stratum corneum of the rumen[5].

The insoluble residues of lymph nodes which were examined for allothigenes also showed evidence of precipitation of silica on a micro scale. Several types of corpuscles including phagocytes, lymphocytes, and red blood corpuscles were observed to have been mineralized by amorphous silica and by silica plus magnesium plus phosphorus, thus giving rise to micro-zooliths. That this process might sometimes occur on quite a considerable scale is evident from the observation that one million mineralized corpuscles were estimated to be present in one prescapular lymph node. There may be a close parallel between this mineralization and the 'mummifying' effect which silica has been found to have on phagocytes which ingest it[12]. In contradistinction to the introduced allothigenes it is proposed to use the term authigenes for zooliths, either macro- or micro-, which are produced by secretion within the body.

We are grateful to Dr. A. B. Edwards, Prof. G. S. Christie and Sir Samuel Wadham for their interest in this work.

CYTOLOGY

The Pachytene Stage in Mammalian Oocytes

Several chromosomal abnormalities have recently been described in human cytogenetics, some of them probably directly and causally related to certain phenotypical effects. All this work was carried out using chromosomes of the mitotic metaphase, mostly from cultures of various cells. The exact identification of any single chromosome is not possible. All 42 autosomes and a pair of sex chromosomes are divided into four or five morphological classes using the length of arms and the position of the centromere as a landmark of identification. The difficulties may be illustrated by the fact that the sex of an individual is determined as male if there is an uneven number of small chromosomes. There is a great need for a more precise method of identification by which individual chromosomes can be recognized.

The study of chromosome morphology in meiotic prophase may perhaps open up some possibility in this direction. Mapping of human chromosomes in the pachytene stage of the spermatocyte is probably only a matter of time, and it is probable that in the near future there will be available a satisfactory pachytene map of human chromosomes from the spermatocytes.

It has been known for some time that meiotic prophase in female mammals starts in the embryonic ovary and stops after the stage of pachytene has been reached. This is followed by a diffuse stage called dictyotene in which the oocytes remain until the time of ovulation.

More detailed investigation on mouse material has shown that meiotic prophase in the oocytes starts

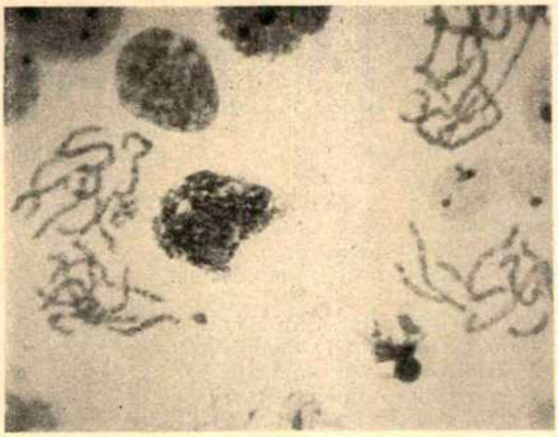

Fig. 1

at about the fifteenth day of pregnancy, when the leptotene stage appears in the nuclei of the young oocytes. This is followed by zygotene and finally by pachytene, which is the best stage for cytological identification of individual chromosomes. A few days after birth all oocytes are in the dictyotene stage and all possibility of chromosomes being identifiable has vanished. Comparison of data obtained here with those (unpublished) of Drs. K. Borum and H. Peters (Finsen Laboratory, Copenhagen, personal communication) indicates that the time of appearance of leptotene and of dictyotene depends on genetic constitution.

Embryonic ovaries taken at about the fourteenth day of pregnancy or any day later can be cultured in a synthetic mixture (*M*-199) for a few days (up to 48 hr. in excellent condition—later the stainability deteriorates). The number of oocytes in the pachytene stage probably increases in the culture. The accompanying photomicrograph shows pachytene in oocytes removed from a 14 days old mouse embryo and kept in the medium at 37° C. for 48 hr.

Although there are great obstacles and difficulties in the application of this method to human material, it is perhaps worth while to keep its potential possibilities in mind.

Absorbance of Feulgen-stained Bull Sperm

IN earlier communications[1,2] it was suggested that both the absorbance and the geometrical dimensions of Feulgen-stained somatic cell nuclei were dependent variables of a common, independent variable, which was considered to be the 'growth process'.

As the genetic complement of a nucleus replicates itself between two consecutive divisions, and as replication implies a strictly orderly arrangement of the participating molecules both in time and space, the growth process can be described as being a process by which molecules are brought from a state of less to a state of higher orderliness. Accordingly the absorbance of Feulgen stained nuclei can be interpreted as being a measure of the ratio between the number of molecules in the states of orderliness and disorder[1]. In the case of somatic cell nuclei the numerical value of this ratio will depend on the type of arrangement of the nuclear genetic complement, the rate of synthesis and the interphase age, while in the case of spermatozoa, which are haploid 'end products', the absorbance is only dependent on the arrangement of the genetic complement.

The modal distribution of measured absorbances from a population of spermatozoa is accordingly interpreted as being not the result of a Gaussian distribution of measuring errors, but as the result of different arrangements of the genetic complement. The mode indicates therefore that either the majority of the spermatozoa possesses identical arrangements of the genetic complement or that the differences in arrangement are so slight as to give rise to differences in absorbance too small to be detectable with the applied measuring technique, while outlying absorbance values indicate differences in arrangement sufficiently large to be measurable.

The feasibility of this interpretation seems to be corroborated by the following results: the distribution of identically and simultaneously treated Feulgen-stained sperm heads from three Ayrshire dairy bulls are shown in Fig. 1, from which it is evident that the three distributions are different. The absorbances are lowest for bull *A*, which is 9·5 years

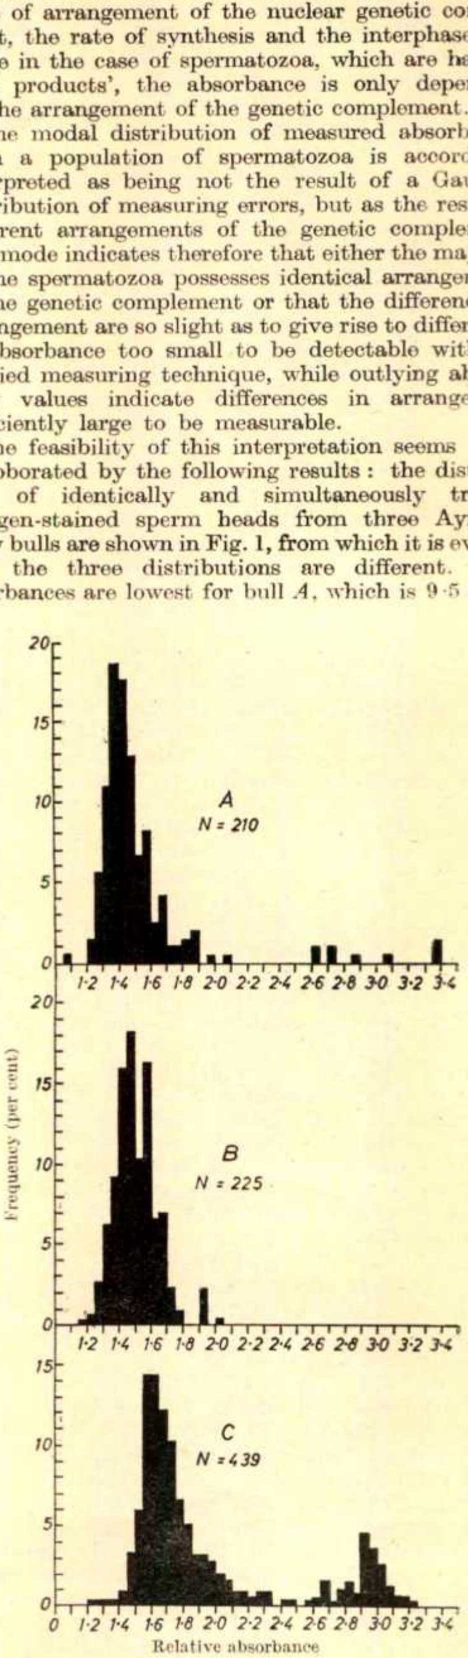

Fig. 1

old and from which 41 daughters averaged 6,691 lb. of milk; highest for bull *C*, which is 7 years old and from which 13 daughters averaged 10,052 lb. of milk; and intermediate for bull *B*, which is 5 years old and from which 13 daughters averaged 7,596 lb. of milk.

Although a correlation between the distribution of absorbances and milk yield in the offspring exists, it should be emphasized that it is not claimed that a given distribution of absorbances is characteristic for a given gene, or genes, or for a phenotypic characteristic, but it seems that the distribution of absorbances might give a relative measurement which possibly can be used as a screening test. Thus assuming that the gene(s) for high milk-yield in the offspring were present in spermatozoa with the genetic complement arranged in such a way as to give rise to absorbances of 1·5 or more, and assuming the fertilization to be a completely random phenomenon and the population of measured sperm heads to be representative of the total sperm population, the probability of the fertilizing spermatozoon having an absorbance of five or more will be highest for bull *C*, lower for bull *B* and lowest for bull *A*.

A fuller account of more extensive work is in progress and will be published elsewhere.

The samples of sperm were kindly supplied by the Scottish Milk Marketing Board's cattle breeding centres in Inchinnan and Perth.

This investigation was supported by a grant from the British Empire Cancer Campaign.

Giant Nuclei in the Earthworm *Lumbricus*

GIANT nuclei have been found by me in the epithelial cells of the pharynx in the earthworm *Lumbricus* sp. The pharyngeal epithelium of the earthworm was extensively investigated by Keilin[1], but no mention of giant nuclei was made in his paper.

Several hundred earthworms were purchased from a Kansas City supplier and were sectioned and stained with hæmatoxylin and eosin or by the Feulgen reaction. Giant nuclei were found most extensively in the pharynx and decreased in numbers toward the œsophageal region. Cytometric measurements were made using the greatest diameter and the diameter perpendicular to it. Fifty diameters of the more numerous small nuclei averaged 5·9µ. Fifty diameters of randomly selected giant nuclei averaged 21µ.

Giant nuclei were not found in *Lumbricus* sp. which were obtained from the following sources: a supply house in Chicago, Ill.; Chanahan, Ill.; Lyons, Kas.; Mission, Kas.; Oseola, Mo.; Weld, Maine; and other areas in Wisconsin, New York State and Canada.

Intranuclear morphology, such as chromocentres, was easily seen in these nuclei. In many instances the nucleolus was found to be bizarrely shaped. These nuclei appear to be polyploid because of the increased amount of Feulgen-positive material and an increase in the number of chromocentres present. Endopolyploidy is most highly expressed in gland cells and such an example is the pharyngeal gland cells of worker bees[2]. Painter[3] believes that there is a relationship between endopolyploidy and protein formation of these gland cells and that the increase of heterochromatic regions and nucleolar organizers is basic in this relationship.

GENETICS

Linkage in *Coffea arabica*

THE *anormalis* factor (*Am Am*) of *Coffea arabica* affects the size of the plant, its branching habit and its leaves, flowers, fruits and seeds. The internodes of the branches are shorter than in the *typica* variety, taken as standard. The leaves are extremely abnormal, often almost palmate and of various sizes. The corolla has a variable number of lobes, the stamens are almost normal, but the style and stigma are very reduced and misshaped. The number of flowers and fruits is normal. The seeds have a slightly corrugated surface. A rather high percentage of locules contains more than one ovule. The *anormalis* shows incomplete dominance in F_1.

The *anomala* mutant also affects the plant growth, its type of branching, the shape and size of the leaves, and the morphology of flowers, fruits and seeds. The number of flowers and fruits is very low and the occurrence of locules with more than one seed is, however, very high in some years. The *anomala* is recessive (*an an*), the F_1 being almost normal, with the exception that, occasionally, a pair of leaves develops with slightly misshaped apex.

The F_1 hybrids of *anormalis* and *anomala* are like *anormalis* heterozygotes; sometimes they have smaller and more irregular leaves, indicating a certain interaction of both factors. Back-crosses with *typica* or *bourbon* plants with the genotype *am am An An* gave indication (Table 1) of linkage of the two factors involved, with a recombination value of about 15 per cent. Due to difficulties in the separation of the classes $\frac{Am\ An}{am\ An}$ from $\frac{Am\ an}{am\ An}$, this recombination value is not precise and can be anywhere between 10 and 20 per cent. Back-crosses with the double-recessive type are difficult to obtain, due to the small number of flowers that it produces.

It is to be noted that the *anormalis* and *anomala* genes, producing rather similar phenotypes and having a very intensive pleiotropic effect, are, up to now, the only factors to give indication of linkage in *Coffea arabica*.

Linkage between Deficiency of Glucose-6-phosphate Dehydrogenase and Colour-blindness

HEREDITARY susceptibility to hæmolysis by drugs and fava beans is believed to be due to a single sex-linked gene. This mode of inheritance would best explain the familial and population data, as summarized recently by Childs and Zinkham[1]. The main element of uncertainty regarding this hypothesis arises from the great variability of the measured blood abnormalities in heterozygous females (*in vitro* glutathione stability test and glucose-6-phosphate dehydrogenase activity).

However, sex-linkage of a trait may be established if it fails to show free assortment with a known *X*-linked character, like colour-blindness. Such a linkage study is being carried out in some of the Jewish communities in Israel which exhibit a high frequency of the enzyme deficiency[2].

Families characterized by a colour-blind son were investigated for enzyme activity. Only families in which both mutant characters segregated with their normal alleles were included in the investigation; each sibship exhibited only one type of colour blindness, according to the rough classification of the Ishihara tables.

Thirty-seven brothers of ten such families were found to segregate as shown in Table 1.

Table 1

	Number of brothers				
Colour vision:	Normal		Deficient		Total
Enzyme activity:	Normal	Deficient	Normal	Deficient	
Family No. 1		2	3		5
,, 2		2	1		3
,, 3		1	2		3
,, 4		2	1		3
,, 5		1	3		4
,, 6		2	1		3
,, 7		2	2		4
,, 8		1	1		2
,, 9		2	3		5
,, 10	1	—	—	4	5
Total	1	15	17	4	37

Each of these ten families thus comprises only two classes of sons, and there is complete lack of re-assortment between the two characters investigated. At the present stage, I am unable to account for the excess of repulsion between the two mutant genes.

These results indicate, therefore, a fairly close linkage between the loci determining colour-blindness and enzyme deficiency, and testify strongly against autosomal inheritance of the latter. They do not exclude partial sex-linkage of this trait, since families in which the trait would have been passed on from a father to all his sons in his *Y*-chromosome would have been excluded from the investigation because of lack of segregation.

I wish to thank Prof. Elisabeth Goldschmidt, of the Department of Zoology, Hebrew University, Jerusalem, for her advice and criticism, and Dr. Ch. Sheba, director of the Hospital and chief of the Department of Medicine (C), for his suggestions and encouragement.

The work was supported by grants from the United States Public Health Service (Grant *A*–2740–*Hema*) and the Rockefeller Foundation (Re: *GA BMR* 5936).

VIROLOGY

Relationship of Hepatoencephalomyelitis Virus and Reoviruses

In 1953, the isolation of a new virus termed hepatoencephalomyelitis virus was described[1]. This was recovered from the fæces of an aboriginal child suffering from a respiratory infection and who later developed alopecia areata. Further work[2] on this virus revealed the following properties: (1) Production of clinically recognizable disease only in suckling mice (commonly observed signs: oily hair, jaundice, peritoneal exudate, ataxia; a 'neurotropic' variant killed infant mice rapidly without these clinical signs). (2) Typical lesions in suckling mice were observed in the brain, cord, liver and heart. (3) Membranes of 110 mμ average pore diameter withheld virus; those of 130 mμ average pore diameter did not. (4) Resistance to ether. (5) Growth in tissue culture and chick embryos. (6) Infection in mice associated with the increased production of fæcal material of exceptionally high fat content. (7) The infection could be transmitted orally to suckling mice.

Agents which appear to be identical with hepatoencephalomyelitis virus have also been isolated in Holland by van Tongeren[3] from human fæces, and in India from mice by T. H. Work (personal communication, 1957).

In 1959, Sabin[4] proposed the group name 'reovirus' for a number of viruses distinct in size and other properties from other well-known enteric and respiratory tract viruses.

Subsequent investigations[5,6] have shown the ubiquitous nature of the reoviruses and revealed the following properties: (1) Membranes of 110 mμ average pore diameter withheld virus; those of 130 mμ average pore diameter did not. (2) Resistance to ether. (3) Growth in tissue culture. (4) Some strains grew in chick embryos. (5) Infection of suckling mice with lesions in the brain, heart and liver. (6) Production of a hæmagglutinin for human group 0 erythrocytes. (7) Three serological types have been determined.

Reoviruses with properties described above have been isolated from fæces of healthy children, children with diarrhœa and children with steatorrhœic enteritis; and from chimpanzees with rhinitis, a monkey with pneumonia, uninoculated monkey kidney tissue cultures, guinea pigs, mice and cattle[6,7].

The similarity of the hepatoencephalomyelitis virus and the reoviruses stimulated the further inquiry reported here. Through the courtesy of Drs. A. B. Sabin and Leon Rosen, the following strains of reoviruses, and antisera to them, were made available: type 1 ('Lang'); type 2 ('Amy' and 'Jones'); type 3 ('Dearing' and 'Abney'). Infection of suckling mice by the intraperitoneal route showed that both the 'Dearing' and 'Abney' strains of reovirus type 3 produced classical hepatoencephalomyelitis virus infection in suckling mice, with peritoneal exudate, oily hair effect, fæces with high fat content and lesions in brain, cord, heart and liver. Neutralization tests in suckling mice with 100 $I.D._{50}$ of hepatoencephalomyelitis virus gave the following results with hyperimmune sera against:

Type 1 ('Lang')	no protection at 1/10
Type 2 ('Amy')	no protection at 1/10
Type 3 ('Dearing')	complete protection at 1/160
Hepatoencephalomyelitis virus	complete protection at 1/320

Neutralization tests in suckling mice with 100 $I.D._{50}$ of reovirus type 3 ('Abney') gave the following results with hyperimmune sera against:

Hepatoencephalomyelitis virus	complete protection at 1/320
Type 3 ('Dearing')	complete protection at 1/160

In addition, (1) a common complement-fixing antigen was shown for both hepatoencephalomyelitis virus and the reoviruses; (2) hepatoencephalomyelitis virus produced a hæmagglutinin for human group 0 erythrocytes; (3) hæmagglutination-inhibition tests confirmed the neutralization tests; and (4) the type 3 reovirus ('Abney' strain) infects suckling mice by the oral route and produces the oily hair effect, and lesions in the liver, brain and heart.

These observations show that hepatoencephalomyelitis virus and the reovirus group are closely related, and that no differences are demonstrable with these tests between reovirus type 3 and hepatoencephalomyelitis virus.

The passage of hepatoencephalomyelitis virus in tissue culture or chick embryos aids in the selection of the 'neurotropic' variant, which does not produce the oily hair effect[2]. A similar change may have occurred in some strains of reovirus primarily recovered by tissue culture techniques. As all the reoviruses so far reported have been isolated primarily in tissue culture, and as the hepatoencephalomyelitis virus strains isolated have first been demonstrated in suckling mice (being particularly noticed by the oily hair effect), it is suggested that selection of variants could well occur in either host by continuous passage before testing the ability of the strain to infect a fresh host.

The facts that hepatoencephalomyelitis virus produces a disease of steatorrhœic type in mice and that the 'Amy' strain of reovirus was isolated from humans with steatorrhœic enteritis suggest that further inquiry should be made to assess the significance of these agents in the etiology of some forms of steatorrhœa in man.

Use of Snake Venom Phosphodiesterase in Place of Pancreatic Ribonuclease for the Testing of Nucleic Acid Preparations from Tobacco Mosaic Virus

Deproteinized plant virus preparations are customarily incubated with pancreatic ribonuclease in order to show that their infectivity is not due to residual virus particles. With tobacco mosaic virus nucleic acid, exceedingly small concentrations of the enzyme (10^{-8} mgm./ml.) are sufficient to abolish infectivity after incubation for 24 hr. at room temperature, whereas tobacco mosaic virus is not affected

Table 1. Infectivities of Tobacco Mosaic Virus (TMV) and of Tobacco Mosaic Virus Nucleic Acid (TMV-NA) after Incubation with Venom Phosphodiesterase for 1 hr. at Room Temperature

† Incubated at room temperature for 1 hr. in the absence of phosphodiesterase.

by a thousandfold higher concentration[1]. However, under these conditions tobacco mosaic virus nucleic acid incubated without enzyme often loses most or all of its activity[1]. Shorter times of incubation necessitate the use of higher ribonuclease concentrations, but at higher concentrations pancreatic ribonuclease, when mixed with plant viruses, inhibits infection[2-4]. This effect occurs immediately after ribonuclease is mixed with the virus and does not increase upon incubation of the mixture[2]. Consequently, as the ribonuclease concentration is increased and the incubation period shortened, the range within which tobacco mosaic virus nucleic acid is inactivated and tobacco mosaic virus is not affected becomes progressively narrower. If one considers that the effect on the virus of a given concentration of ribonuclease is furthermore a function of salt concentration and of concentration of tobacco mosaic virus[4], it becomes evident that the results of incubation studies with ribonuclease must be carefully evaluated before definite conclusions can be drawn.

An enzyme with more preferential action on virus nucleic acid and better stability in solution would be of value. Data presented here show that snake venom phosphodiesterase fulfils these requirements.

The phosphodiesterase was purified from eastern diamond-back rattlesnake venom by the method of Sinsheimer and Koerner[5]. The final preparation contained 2·8 mgm. protein per ml. It was stable at 4° C. for several weeks. Tobacco mosaic virus nucleic acid was prepared by the method of Gierer and Schramm[6]. Mixtures containing 0·5 ml. of an appropriate dilution of tobacco mosaic virus or tobacco mosaic virus nucleic acid, 0·5 ml. of 0·1 *M* buffer, and 1·0 ml. of diluted phosphodiesterase were incubated for 1 hr. at room temperature. Mixtures in which water was substituted for the enzyme or the enzyme was added prior to inoculation served as controls. Infectivity was assayed on plants of *Datura stramonium* L. or *Nicotiana glutinosa* L. by inoculation of 8–16 half-leaves with each preparation. Table 1 gives the results of some of the tests made.

Incubation with the phosphodiesterase led to complete inactivation of tobacco mosaic virus nucleic acid except in those cases where either the enzyme concentration was insufficient or the *p*H value was too low. Tobacco mosaic virus preparations retained approximately 50 per cent of their infectivity regardless of whether the virus was or was not incubated for 1 hr. with the enzyme. Virus preparations of very low titre still produced lesions after being incubated with high concentrations of the enzyme.

Thus, venom phosphodiesterase, like pancreatic ribonuclease, readily destroys the activity of preparations of tobacco mosaic virus nucleic acid. Unlike pancreatic ribonuclease, phosphodiesterase only weakly inhibits infection with the virus.

The preferential action of the phosphodiesterase may be a consequence of its high *p*H optimum. At *p*H 5·1, the enzyme had only a slight effect on the infectivity of tobacco mosaic virus nucleic acid. The virus, on the other hand, was equally inhibited at *p*H 5·1 and 7·5 whether it was incubated for 1 hr. or not. This suggests that the inhibition of tobacco mosaic virus infectivity was non-enzymatic or, if enzymatic, that it must have occurred during a sensitive stage after inoculation. Assuming that enzymatic action did occur after inoculation, the relatively slight effect of phosphodiesterase on virus infectivity can readily be explained by the unfavourable *p*H value for enzymatic action within the host plant.

SOIL SCIENCE

C Horizon of the Soil Profile

A recent communication by Willimott and Shirlaw[1] refers to the *C* horizon and its absence in soils developed from fluvio-glacial and alluvial deposits near Durham City. These authors use a definition of *C* horizon as "unconsolidated parent material substantially similar to that from which the solum has developed". This is the definition of the U.S. Department of Agriculture[2], in which the *C* horizon is described as "weathered parent material" and *D* includes "any stratum which is not parent material". It is widely held that such a distinction between unconsolidated and consolidated parent material is difficult to maintain. In the case of a rock and an overlying drift or weathered material derived from similar rock, it has been the practice to describe the latter as parent material and the former as parent rock. Such a differentiation is not universally favoured, but an indexing of these cases as C_1 (unconsolidated parent material) and C_2 (rock, the weathering of which is producing C_1) is preferable to the use of D in this case. D as a symbol is then confined to material not contributing to the overlying solum but influencing it in some way, such as in its moisture relations. This use of C_1 and C_2 is that adopted by Kubiena[3].

It is, in practice, a difficult line to draw between unconsolidated and consolidated material, if the indexing of these is to separate them sharply as C and D. As an example of the difficulty if C is maintained only for unconsolidated material, we can consider a progression in parent rock from alluvial clay, through unconsolidated clay such as many Jurassic and more recent rocks, soft shales and harder Palæozoic shales, to Cambrian slates. At which point in such a series do we decide that the consolidation has proceeded so far that classification as C horizon is no longer appropriate ? The use of C_2 and C_1 as symbols indicates much more clearly the relation of rock and weathered rock to soil. It frequently happens with sedentary or nearly sedentary soils that rock weathering and soil formation take place so that A or A and B horizons overlie solid rock directly ; that is to say, pedogenic processes keep pace with rock weathering and no weathered rock exists which has not been subjected to further pedogenic weathering. All such soils on the U.S. Department of Agriculture system would be indexed as variants of A, D or A, B, D profiles. This seems inadequate to express relationships of soil and rock clearly. On the Kubiena system, the soils under discussion are classified as A, C_2 or A, B, C_2. A, B, D soils are confined to those in which the solum has no derivation, direct or indirect, from the D horizon.

Willimott and Shirlaw suggest that the absence of C horizons in soil profiles has not previously been reported for soils of the United Kingdom. It is, however, the general case that in layered alluvial deposits, material is often absent which can be accurately indexed as C horizon. In the common case of a medium or heavy-textured soil overlying gravel, the gravel is D horizon material, and profiles may vary rapidly in type between A, B, D ; A, B, CD, D or A, D, as is the case in alluvial soils along some rivers in North Denbighshire, surveyed with J. F. Harrop[4]. Such alluvial soils have been described and indexed as variants of A, B, D profiles in earlier *Memoirs of the Soil Survey of Great Britain*. For example, Muir[5], considering alluvial soils derived from varying proportions of Silurian and Old Red Sandstone rocks, indexes these as S, B, D or S, BC, D (using S to indicate the surface horizon of a cultivated soil, equivalent to A or Ap in some usages). Non-alluvial soils without C horizons are also described in the area covered by this memoir. Hobkirk and Faw series occur developed on thin till of Old Red Sandstone origin overlying Old Red Sandstone rock. This latter can vary greatly in lithology and is classified as D horizon. Muir states (*op. cit.*, p. 64) : "With this series (Hobkirk) it is unusual to find a C horizon, for the till is generally very shallow. The properties of the D horizon can vary greatly". Again, Glentworth[6], in his consideration of alluvial soils, indexed only an S horizon, while the Bogtown association, developed on what is believed to be interglacial lacustrine clay, is represented by one profile of horizons S and G only, which overlies a buried soil. Such composite profiles, in which C horizon material is no longer present, are frequent, especially in hill areas. Colluvial deposits may cause material derived from one rock-type to overlie another, also giving an A, B, D profile. In this case the C horizon material may be located higher up the slope, not in physical connexion with a solum developed from it.

In the final example quoted by Willimott and Shirlaw, it would appear helpful to consider using CD (or C_2D) as a horizon symbol. This indicates that the material so indexed has contributed in part to the overlying solum. The solum has, however, been partly derived from other sources. The CD definition indicates that such material also fills in part the definition of D material as a material influencing the solum, but unlike that from which the solum has been formed. The case of shallow soils developed from mixed till including limestone, overlying limestone, would then be indexed by variants of A, CD.

Such cases are widely met with in Britain ; for example, in my experience in both North and South Wales, where shallow drift overlies rock which is D or CD horizon. In Glamorgan, drift of gravelly outwash of mixed origin, and silty loam possibly derived from Carboniferous shales, both overlie Carboniferous Limestone, and where the drift is shallow, C horizon material may be missing. In North Wales, an A, CD profile is frequent in shallow soils, again over Carboniferous Limestone[4].

[5] Muir, J. W., *The Soils of the Country round Jedburgh and Morebattle* (H.M.S.O., Edinburgh, 1956).
[6] Glentworth, R., *The Soils of the Country round Banff, Huntly and Turriff* (H.M.S.O., Edinburgh, 1954).

D. F. **Ball** has raised a number of points arising out of our original communication on this subject. The distinction between the definition of soil horizons adopted by the U.S. Department of Agriculture[1] and that by Kubiena[2] turns on the question of the nomenclature of the solid rock. In the first system this would be designated as a D horizon and, in the other, either as a C_2 or a D horizon depending on its relationship to the regolith. Whichever system is adopted, and each has its merits, the essential requirement remains that a C horizon should bear a direct relationship to the solum developed. In a recent text it is noteworthy that Thompson[3] states that : "The recent trend is to describe the consolidated parent material below the C horizon (or immediately beneath the B horizon) as the D_r horizon".

It may therefore be useful to consider the advantages of the system accepted by the U.S. Department of Agriculture :

(1) This system has long been accepted by pedologists and any change, which may well cause con-

fusion, can only be justified provided it leads to clarity and facility in the recognition of debatable soil-horizons.

(2) The underlying unweathered solid rock cannot be accepted as part of the regolith ; to designate it as C_2 is therefore unacceptable.

(3) The correctness of the view that there is no necessary correlation between the "weathered parent material" and "unconsolidated parent material" is agreed. The *C* horizon of the U.S. Department of Agriculture may or may not be partly consolidated.

(4) We are dealing with soil formation, and the question whether the parent material is consolidated or not has no bearing on profile designation. There would seem to be no complication on the progression of parent materials from alluvial clay to Cambrian slates, cited by Ball, which incidentally can be found without resorting to widely different geological ages. On this interpretation, in the example quoted, the soft clay or shale, in the same way as the slate, is acceptable as a *D* horizon when it can be seen to be unweathered, that is, unaltered by pedogenic processes.

The findings of Muir[4] and of Glentworth[5] on certain of the soils of Scotland mentioned by Ball (*loc. cit.*), as well as the observations of Ball in Wales, are of interest in this context and we are indebted to him for directing our attention to them. These experiences offer substantial confirmation of the view that soils with no recognizable *C* horizon are widespread. Indeed, since the publication of our communication[6], profiles with similar characteristics have been encountered in aeolian soils in Libya[7]. A number of profiles, exhibiting a horizon succession of the *A*, *B*, *D* type, were studied in an area located about 25 miles south of Misurata in the region of Taourga oasis (Tripolitania). Soil profiles with a horizon succession of *A*, *D* type were also recorded. It is hoped to publish details of the Taourga soil survey at a later date. Furthermore, in the course of a detailed survey of Malta, Bowen-Jones and Dewdney[8] reported very shallow loams developed over limestone in which a succession of *A*, *D* horizons was recognized in the profile. Here admittedly human activity had contributed in part to the soil material ; nevertheless, on level areas little exposed to soil wash, an *A*, *D* profile develops with time. Thompson (*loc. cit.*) also reports profiles of this type in the United States.

The designation of a *CD* horizon in the profiles developed over magnesian limestone in County Durham may provide a solution to the difficulty previously discussed[6]. On the basis of the U.S. Department of Agriculture classification of a *D* horizon, the *CD* indexing would appear to be valid since it indicates the dual role taken by this horizon in supplying part of the parent material and as constituting the underlying rock. A clear definition is necessary, however, since other profiles may carry a similar designation but with different significance. For example, certain rendzinas[9] are indexed *A*, *AC*, *C* ; in this case the significance of the *AC* designation is that the horizon represents a transitional zone only between *A* and *C*. Again, the designation *AG* indicates that the *A* horizon is gleyed.

Soils in which no true *C* horizon can be observed represent a special case. It may be useful to consider three typical examples, namely : alluvial soils, shallow drift soils and deep fluvioglacial soils.

Alluvial soils. Some of the soils developed on alluvium referred to by Ball, for example, the Bogtown association studied by Glentworth[5], exhibit a solum which is still actively developing and evolving. Here the solum is shallow and may actually be accumulating. The true parent material is all transported. Furthermore, the pedogenic process is keeping pace with the deposition of parent material. In this case the absence of a true *C* horizon is inevitable so long as the deposit is shallow. Although the alluvial deposits studied at Durham[10] were much deeper (up to 10 ft.), a true *C* horizon was again absent.

Shallow drift soils. In the shallow drift soils of the Hobkirk and Faw series, studied by Muir (*loc. cit.*), the parent material was originally derived from a distant origin. This forms drift, which after pedogenesis is too shallow to retain an unaltered layer of parent material below the solum. Here the *C* horizon occurs only in the initial stages of solum formation.

Fluvioglacial soils. In the deep fluvioglacial soils observed at Durham[11] the potential parent material, up to 23 ft. thick, is composed of thin beds of heterogeneous material—gravel, sand and clay. With the development of *B* horizons, solum formation occurs down to a depth varying roughly between 6 ft. and a maximum of 12½ ft., and is underlain basically by *D* horizons. Owing to the varied and heterogeneous character of the deposits, a *C* horizon is not now present. In the course of time, pedogenesis allows successive *D* horizons to be transformed into true *B* horizons. Whichever method of classification is applied, the successive horizons beneath the *B* horizons would be designated *D*.

It is therefore inevitable that in the case of the shallow alluvial and the shallow drift soils, profiles of the *A*, *B*, *D* type will develop. In both cases these represent very shallow soils. The fluvioglacial soils are different because there is adequate parent material which has been exposed for a period sufficient for a complete soil profile to evolve. Here the *A*, *B*, *D* type soils are the result of the inherent geological properties of the fluvioglacial deposits which, in time, allow a succession of *D* horizons to change into *B* horizons as the profile evolves. It was to this latter class of *A*, *B*, *D* type profiles that we wished originally to direct attention.

Phosphate Requirement of Lupins grown as a Pioneer Crop on Culm Measure Soil with Impeded Drainage

Lupins are reputed to be one of the most efficient extractors of phosphate from soil among farm crops and have been used extensively on the Continent as a pioneer crop on soils of very low phosphate and lime status.

In order to explore the possibility of making use of lupins as a pioneer crop on Culm Measure soil which was poorly drained, acid and of low phosphate status, a newly cleared field at the North Wyke Experimental Station, Devon, was sown with lupins in 1958. In this field an observational experiment with phosphate was conducted in which a large response to superphosphate was observed. Consequently, in 1959, a replicated field experiment was laid down in order to determine if this effect was due to phosphate or to other constituents of superphosphate.

The results of this experiment are given in Table 1, from which it can be seen that the very marked yield responses are all associated with phosphate applications, indicating that the effect of superphosphate was due to its phosphate and not to any other constituent.

Further, the figures for phosphorus content in the plant dry matter strongly suggest that the yield responses were caused by phosphate applications and not, for example, by a phosphate/molybdenum interaction[1]. The similarity between the plant nitrogen contents also suggests that the supply of trace elements was adequate.

This experiment does not support the assumption of long standing that lupins are able to obtain phosphorus from relatively insoluble soil phosphates. This finding is in agreement with an observation made by Schofield and Nethsinghe[2], who equilibrated a mixture of a surface soil derived from Upper Greensand and river sand with phosphate labelled with phosphorus-32 and grew cabbage, barley and lupins in the mixture. Allowing for phosphorus in the seeds, they found that six weeks after potting, the specific activity of the phosphate taken into the plants was the same for all three species, and was equal both to that in the solution after equilibration and to that in the calcium chloride extract of soil from similarly treated pots without plants. Hence none of the crops, including lupins, mobilized insoluble phosphates, that is, isotopically non-dilutable phosphorus.

When lupins can thrive without phosphate application, even on soils with a very low phosphate status, the explanation is more likely to be an ability to obtain phosphate from the deeper layer of the subsoil outside the reach of more shallow rooting crops. In the experiment described, impeded drainage possibly prevented the lupins from drawing on phosphate reserves in the subsoil and consequently the crop was very responsive to phosphate.

Table 1. PHOSPHATE EXPERIMENT IN LUPINS (VARIETY WEIKO III) SOWN JUNE 5, HARVESTED AUGUST 29, 1959

Soil: Culm Measure, impeded drainage with clay subsoil. History: old woodland cleared in 1957 and fallowed in 1958. Soil analysis: citric-soluble phosphate, 50 p.p.m., and potassium (K_2O), 184 p.p.m.; organic carbon, 3·1 per cent; *p*H in water, 4·2

Treatments 1–4 received 80 lb K_2O/acre plus the following:	Rate of application per acre	Yield of dry matter (cwt./acre)	Phosphorus in dry matter (lb./acre)	Percentage in dry matter			
				P	K	Ca	N
1 Nil	—	2·2	0·25	0·105	1·63	0·203	2·81
2 Single superphosphate	120 lb. P_2O_5	17·1	4·03	0·206	1·73	0·352	2·53

PSYCHOLOGY

Measurement of Psychomotor Perseverative Tendencies

One of us (S. D. P.)[1] has described what he believes to be a novel procedure in psychological research. It is based on a well-attested observation that, if individuals repeat after a brief interval of time a section of a simple maze, some very surprising perseverative tendencies become apparent.

When shuffled among a group of similar maze threadings by other individuals, the first performance can be correctly matched with the second in about 90 per cent of cases, even when names or all other identifying marks are concealed from view. The percentages correctly matched have been tabulated for 800 pairs of performances, and show apparently little differences in the matching ability of experienced observers. The phenomenon is considered remarkable on two counts. In the first place it is surprising that recognizable patterns occur on the basis of a single repeated performance of an activity which is new in the experience of the subject. As is well known, habits of action are ordinarily established only on the basis of very many repetitions of the activity in question.

In the second place, the matching process depends on similarities in lines and turnings at eight different points. The performance is so arranged that it would be difficult, not to say impossible, for the individual to recall consciously the kinds of lines or the types of turns he made on his previous attempt. This unawareness is heightened by the fact that his attention is distracted by the necessity of choosing the course to be pursued to find his way out of the maze. Yet though he may be unable to describe verbally or to demonstrate the kind of turn he made at any particular point, yet he usually tends to repeat his original pattern. The strength of this tendency varies; in some individuals it is so strong that the pattern is still clear after a year's interval between performances; in 10 per cent the repetitive tendency is so weakly impressed that their records are unmatchable even when the lapse of time is only 20 min. It may well be that the distraction of planning the course allows subconscious retention to play its full part. There seems no reason for believing that this perseveration differs in nature from that displayed in gestures or other automatic expressive movements.

However, the demonstration of this phenomenon would amount to little more than a psychological stunt if the pattern of similarities cannot be expressed in the form of a numerical score that would represent the strength of the subconscious tendency. We and our co-workers at the University of Hawaii have devoted considerable time and effort to developing such a score by projecting the paired performances on a large screen. Four psychologists, having first set up standards of comparison, allotted points to each pair of turns in the maze performance according to their degree of similarity, and also to the place of beginning and to the style of going out the final exit. These ratings were then averaged and summated as a score. It seemed to be a safe conclusion that very high scores distinguished individuals with rigid standards of performance, whereas low scores signified less consistent or persistent methods of motor expression. No value judgments with regard to these differences can be assigned at the present stage of our research. The system of allotting conformity-flexibility scores was described and discussed in the articles cited. Obviously, definite theoretical assumptions were premature until more objective scoring methods could be used.

We are now exploring what promises to be a much more reliable approach. We are attempting to devise an IBM scanning procedure such that the pencil tracing on the Porteus Maze will in effect be plotted and recorded in an IBM 650 co-ordinate system. We propose to use in a first possible method of scanning an opaque, enlarged projection of a Porteus Maze section on a mark-sense IBM card. An experimenter will then fill in those circles on the mark-sense cards that the line tracing from the Porteus Maze crosses. From the mark-sense card the IBM machine will automatically punch a regular card.

An alternative method will discard the use of the opaque projector should it prove to be too unreliable for an experimenter to follow the enlarged tracing on an IBM card. With this method we will attempt to print enlarged photographs of the pencil tracing on sensitized IBM cards. The experimenter then might find it easier to fill in the mark-sense circles and his measuring discriminations therefore might be more reliable. When our scanning procedure is perfected, with proper subsequent programming, we should be able to score in a completely objective manner characteristics of the pencil tracings that have previously been found to be important in the matching process.

Once a reliable measure of the perseverative tendency has been achieved, we can then study the behaviour of groups segregated by age, sex, race, intelligence, social adjustment, mental stability, etc. Whether or not the procedure will demonstrate the influence of subconscious retention is not at present of crucial importance.

The fact that the new approach differs from other personality assessments is worth emphasizing. It does not depend on questionnaires, or verbal reports from the subject. He is not required to reproduce or imitate, so that no creative or artistic ability is involved. The situation exhibits a minimum of external structuring, but on the other hand presents to the subject of the experiment a maximum of opportunity to display his characteristic styles of response, with no intervention by the observer. Nor does the former have any knowledge of the significance of his reactions. Hence the scoring comes closer to what Eddington has termed pointer readings, so familiar to physicists and chemists. It is true that experimental psychologists also use similar measurements in studying sensory phenomena. We believe that our approach takes in larger sections of behaviour than if the eye or the ear is being studied, and is less likely to issue in a psychology of 'bits and pieces'. In other words more of the whole man is engaged and the style of his habitual or everyday reactions is more definitely indicated.

It is perhaps unfortunate that the Porteus Maze Test, first published forty-five years ago[2], forms the basis of the new procedure, since psychologists may easily jump to the erroneous conclusion that this constitutes merely another application of a very old test. As there are neither right nor wrong responses, and hence no successes or failures as in the Maze Test, the two applications are entirely different. The situation is analogous to the two uses of a hammer, which can be used for driving in or extracting nails, dependent upon which end of the hammer-head is employed. The main connexion with the test is that eight designs of a regular Maze series are first threaded by the subject before he is asked to repeat the eleven-year design which occurs about the middle of the series. The sole aim of this is to interpose a number of other stimuli and responses so as to make it unlikely that the individual will have any conscious recollections of the details of execution previously carried out. The essential difference is that the psychologist is now interested in what the individual does, and not in what he ought to have done.

The main reason for this communication is the realization that the task of developing more exact methods and their application is difficult. It is hoped that appreciation of the new avenues of potential psychological inquiry which could be opened up may attract the interest and co-operation of others. As one example, it would be indeed interesting to discover at what age we tend to become 'set' in our ways and thus less flexible in action or judgment, or whether some individuals are immune from this process of 'neurosclerosis' as an accompaniment of ageing.

A secondary aim is to make the methods used more intelligible to scientists than are some of the clinical approaches of psychology and psychiatry. The fact that funds may not be available here for the continuation of the project makes it all the more desirable that other workers be more fully appraised of an approach that appears to be promising for the further study of human behaviour.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, February 27

Operational Research Society (in the Lecture Theatre of the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Ir. A. H. Schaafsma (Holland): "The Meaning of OR for Production Planning".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Sir John Hunt, C.B.E.: "A Summer Expedition to Greenland".

Tuesday, February 28

Royal Institution of Naval Architects (at the Institute of Marine Engineers, 76 Mark Lane, London, E.C.3), at 5.30 p.m.—Mr. J. M. Murray and Mr. H. N. Pemberton: "Safety of Nuclear Marine Propulsion Plant".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. A. G. Spencer: "Hypertension and Unilateral Renal Disease; the Selection of Patients for Surgery".* (Fourteenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

University of London (at the Gustave Tuck Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. A. B. Hart: "The Fuel Cell".* (Second of five lectures on "Generation of Electricity without the use of Rotating Machinery".)

Illuminating Engineering Society (at the Royal Institution, Albemarle Street, London, W.1), at 6 p.m.—Sir Graham Sutton, F.R.S.: "Long Range Weather Forecasting". (Sixth Trotter-Paterson Memorial Lecture.)

Institution of Mechanical Engineers, Steam Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Advantages of Increased Pressures and Temperatures and Ratings of Large Steam Power Plant".

Society for Analytical Chemistry, Physical Methods Group (in the Cuthbert Wallace Lecture Room, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2), at 6 p.m.—Meeting on "Physical Methods of Analysis Used in Medical Research".

Society of Chemical Industry, Corrosion Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Cathodic Protection Panel Meeting. Mr. M. G. Duff and Mr. P. Clark: "External Protection of Floating Craft".

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Dr. V. S. Griffiths: "Three Terminal Bridge Measurements and Automation".

Wednesday, March 1

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Dr. D. G. King-Hele: "Satellites and the Earth's Outer Atmosphere" (Symons Memorial Lecture).

British Institution of Radio Engineers, Television Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Mr. L. H. Bedford: Inaugural Address.

Institution of Electrical Engineers; and the Royal Aeronautical Society (at the Royal Aeronautical Society, 4 Hamilton Place, London, W.1), at 6 p.m.—Discussion on "The Training of Electrical and Electronic Engineers for the Aircraft Industry", opened by Mr. G. S. Bosworth.

Institute of Physics and the Physical Society, X-ray Analysis Group (at 47 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. W. A. Wooster: "Crystal Symmetry—Old and New".

Wednesday, March 1—Thursday, March 2

Iron and Steel Institute, Iron and Steel Engineers Group (at 4 Grosvenor Gardens, London, S.W.1) at 2.30 p.m. on Wednesday and 10 a.m. on Thursday—Forty-second Meeting.

Thursday, March 2

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. J. C. Ruegg: "On the Tropomyosin–paramyosin System in Relation to the Viscous Tone of Lamellibranch 'catch' Muscle"; Miss Jean Hanson and Mr. J. Lowy: "The Structure of the Muscle Fibres in the Translucent Part of the Adductor of an Oyster".

Institute of Physics and the Physical Society, Acoustics Group (in the Physics Department, Imperial College of Science and Technology, South Kensington, London, S.W.7), at 5.30 p.m.—Mr. A. E. Crawford: "Lead Zirconate–Titanate Piezoelectric Ceramics".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. N. N. Hancock and Mr. P. L. Taylor: "The Place of Formal Study in the Post-Graduate Training of an Electrical Engineer".

Royal Institution, Library Circle (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mr. A. K. Parker: "The Function of a University Press".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. J. D. N. Nabarro: "Oral Hypoglycaemic Agents".* (Last of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

Institute of Metals, London Local Section (at 17 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. J. A. Catterall: "Progress in the Electron Theory of Metals".

Royal Institute of Chemistry, London Section (at West Ham College of Technology, Romford Road, London, E.15), at 7 p.m.—Dr. S. A. Miller: "Chemicals from Acetylene".

Friday, March 3

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 10.45 a.m.—Symposium on "The Experimental Taxonomy of Flowering Plants". Speakers include Prof. D. H. Valentine, Dr. P. H. Raven, Dr. A. D. Bradshaw, Dr. N. W. Simmonds, Dr. J. R. Ellis, Dr. M. Borrill, Dr. K. Jones and Prof. I. Manton.

Society for Analytical Chemistry (in the Meeting Room of the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.15 p.m.—Annual General Meeting, followed by Mr. R. C. Chirnside: "The Enlargement of Horizons in Analytical Chemistry".

Association of Consulting Scientists, and the Forensic Science Society (at the School of Pharmacy, Brunswick Square, London, W.C.1), at 5 p.m.—Colloquium on "The Expert Witness".

Institution of Electrical Engineers, Medical Electronics Discussion Group (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "The Clinical Value of E.E.G. Recording" and "Present Trends in General Purpose E.E.G. Recorders", opened by Mr. H. B. Morton and Mr. H. R. A. Townsend.

Royal Aeronautical Society, Rotocraft Section (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. H. W. Mitchell and Mr. S. G. Lennox: "Helicopter Approach Aids".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Lawrence Bragg, F.R.S.: "The Development of X-ray Analysis".

Saturday, March 4

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. A. W. Smith: "Explorations on the Bolivia–Peru Border".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Experimental Officer (with at least G.C.E. in five subjects including two (science or mathematics) at "A" level, or equivalent, and laboratory experience in chemistry or biochemistry) to assist with investigations on sheep metabolism—The Secretary, Institute of Animal Physiology, Babraham, Cambridge (March 4).

Assistant in Biochemistry in St. Salvator's College—Joint Clerk to the University Court, College Gate, St. Andrews (March 4).

Head (highly qualified experienced person) of the Department of Physics—The Bursar, College of Advanced Technology, Gosta Green, Birmingham 4 (March 5).

Scientific Officer (with a good honours degree in mathematics) or Assistant Experimental Officer (with a pass degree or equivalent) in the Statistics Section, to do advisory work on the design and analysis of experiments, and research work on biometrical problems—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (March 6).

Leverhulme Research Fellows (2) (suitably qualified graduates) in Radio-Astronomy, for research in some aspects of radio-astronomy, using the radio-telescope at the University's Nuffield Radio-Astronomy Laboratories at Jodrell Bank—The Registrar, The University, Manchester 13 (March 7).

Lecturer in Physics—The Registrar and Secretary, King's College (University of Durham), Newcastle upon Tyne 1 (March 10).

Senior Lecturer in Mathematics at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, March 10).

Deputy Librarian (with a good honours degree and experience in a university or similar academic library, and preferably with professional library qualifications)—The Secretary, University College, Gower Street, London, W.C.1 (March 11).

Leverhulme Research Fellow in the History and Philosophy of Science—The Registrar, The University, Leeds 2 (March 17).

Assistant in Biochemistry in the Department of Physiology and Biochemistry, Queen's College—Joint Clerk to the University Court, Queen's College (University of St. Andrews), Dundee (March 18).

Assistant Lecturer (with a special interest in experimental psychology) in the Department of Psychology—The Secretary, University College, Gower Street, London, W.C.1 (March 18).

Lecturer in Geography—Joint Clerk to the University Court, Queen's College (University of St. Andrews), Dundee (March 18).

Senior Lecturer or Lecturer (graduate in medicine, with special experience in virology) in the Department of Bacteriology—The Secretary, The University, Aberdeen (March 18).

Lecturer or Assistant Lecturer (preferably specialized in inorganic chemistry) in Chemistry at the University College of Ghana—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 20).

Lecturer in Physics—The Secretary, The University, 38 North Bailey, Durham (March 25).

Senior Lecturer and a Lecturer in the Department of Physiology, University College, Ibadan, Nigeria—The Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, London, W.C.1 (March 27).

Biochemist (with postgraduate experience and preferably some knowledge of bacteriological techniques) to assist in a research project on bacterial polysaccharides—The Director, Central Enteric Reference Laboratory, Central Public Health Laboratory, Colindale, London, N.W.9.

Editorial Assistant (with a university degree in science or technology, and preferably at least two years postgraduate experience in science or industry)—The Manager, *Nature* Office, Macmillan and Co., Ltd., St. Martin's Street, London, W.C.2.

Experimental Officer (graduate, or with A.R.I.C., H.N.C., or an equivalent qualification and experience in the use of techniques of paper and column chromatography) in the Nutrition Department, for biochemical research on problems of protein and amino-acid metabolism—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 61/6.

Fellow or Lecturer in Philosophy—The College Secretary, Balliol College, Oxford.

Head (with the qualifications, teaching and research experience necessary to secure recognition as a teacher of the University of London) of the Department of Physics—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3.

Laboratory Technician (with biochemical experience) to work in the Department of Chemical Pathology on research connected with muscle diseases—The Secretary, Institute of Neurology, National Hospital, Queen Square, London, W.C.1.

Masters to teach Physics; Mathematics; and Geography—The Headmaster, King's College School, Wimbledon, London, S.W.19.

Senior Lecturer (physicist, with experience in university teaching and interested in the problems of radiation safety) in Health Physics, for duties which will include the organization of postgraduate courses on the nature and control of radiation hazards, inauguration of research and the supervision of radiation safety throughout the College—The Secretary, Royal College of Science and Technology, George Street, Glasgow, C.1.

Senior Lecturer (with qualifications and experience to teach mathematics for the Diploma in Technology courses and for Degree courses in engineering and science) in Mathematics—The Registrar (Dept. D), Bradford Institute of Technology, Bradford 7.

Senior Physicist (with some experience in hospital physics) to act as deputy to the Principal Physicist and to take responsibility in radiation physics and isotope work—The House Governor, King's College Hospital, Denmark Hill, London, S.E.5.

SCIENCE AND THE HUMANITIES

JUST over a century ago, J. S. Mill, in his famous essay on liberty, remarked that "the general tendency of things throughout the world is to render mediocrity the ascendant power among mankind". He added that there is always a need for persons not only to discover new truths and point out when what were once truths are true no longer but also to commence new practices, and set the example of more enlightened conduct, and better taste and sense in human life. All that is still profoundly true to-day, and in fact the advent of the mass media of communication has accentuated the danger of mediocrity or worse. Those passages could well have been in the mind of Dr. Caryl Haskins in writing his report for 1959–60 as president of the Carnegie Institution of Washington*, which once again gives a percipient and imaginative survey of the inter-relations of the scientific disciplines with themselves and with the society in which they are nurtured.

While the present report follows closely on last year's report and develops further the same lines of thought then advanced, particularly those arising out of consideration of a real or imagined dichotomy between the scientific and non-scientific world, such as Sir Charles Snow discussed in his Rede Lecture, "The Two Cultures", it is nevertheless fully independent. In her recent life of Lord Lugard, in writing of Lady Lugard, Dr. M. Perham observes: "Even to-day . . . the exceptional and independent mind can often be traced to some divergence from the usual course of schooling which has given both stimulus to thought and freedom to read at will". Although Dr. Haskins's address can scarcely be described as an exposition of this text, it is clear enough that he is profoundly disturbed at some educational tendencies to-day, and that he places very high among his presidential responsibilities that of fostering the exceptional and independent mind, and giving such minds every opportunity to render the contributions to scientific and technological advance which they alone can make.

Dr. Haskins begins by emphasizing the vistas of insight and wonder inconceivable to our forefathers, which we enjoy because of the unparalleled advances in our appreciation and comprehension of Nature, and suggesting that, in consequence, this generation may be standing at a major cross-road of history and living in that deep travail which more than once has preceded and ushered in a Golden Age. The brilliance and variety of man's concepts to-day, the diversity of his imagination, the extent of his practical power to shape and to use his material environment, perhaps even the penetration of his understanding, have never been remotely rivalled in all earlier history, nor have the dangers of his very existence seemed as vivid, as omnipresent, as remote from resolution. While we are convinced that the values in which our society is rooted are fundamental to us, yet we are constantly haunted by the feeling—and the evidence—that the means by which we have traditionally implemented and expressed them in the past, if projected into the coming years without innovation and imagination, will be inadequate to our future.

What is less obvious is the challenge that this contrast presents, and Dr. Haskins reminds us that the great ages of mankind, the ages of the most radical changes and the biggest advances, the ages that later generations of men called great, were not the times of easy optimism when man thought everything discovered, everything designed, everything finished. As Whitehead wrote, on the whole the great ages have been unstable ages. Greatness and ease, vast innovation and untroubled stability, are no more compatible among nations or in a world community than they are among individuals. To-day the United States is predominantly a scientific and technical nation, living in an age itself characterized by the explosive development of science throughout the world, and Dr. Haskins asks accordingly whether there may not be significant things which the very structure of science as a way of life could say in aid of the understanding of ourselves, of this age and the task of the American nation—of an age and a nation profoundly shaped by science at a secular level and at a deeper and more spiritual level too.

That question could well be addressed to Britain also, and the answer we give to it should determine very largely the answers to be given to many of the questions now arising in regard to the expansion of university and technological education, of specialization in the sixth forms of schools and elsewhere, and of the nature and extent of general education. Dr. Haskins develops his theme with imaginative insight to show how in the growth of modern science from the time of Leonardo da Vinci it has been sensitively responsive to the moods and needs of men, portraying accurately the successive ages which nourished it. Everywhere it took its character from the conspicuous needs and opportunities of the time, developing greatness in those areas where it was most needed; and in turn its spirit was everywhere reflected in the society that it served. Surely it is not accidental, he argues, that the centuries of the flowering of modern science have also been the centuries of the rise of the Western concept of the dignity, the uniqueness, and the essential worth of the individual, or that these were also the centuries of the genesis and ascendency of the modern Nation-State as we understand the term to-day.

While in these four centuries there have been comparatively static or satisfied interludes, the main trends in science have been marked by instability, vast shifts in man's concepts of his universe and his place in it, and of his own very constitution and nature, delight in ideas, or fascination with them because of their compelling sweep and force, and an overwhelming urge to communicate them broadly and to share widely in them. The ages that have witnessed these trends have been characterized, too, by the attainment of new levels of physical well-being and of the moral and spiritual horizons and opportunities of the individual. Simultaneously have come, both as cause and consequence of these developments, demands for innovation in the structure of society, reflected in social and political insecurity and in rapidly shifting patterns of political and social organization. The more we contemplate our own time, the more it seems to resemble those earlier dynamic and critical eras of Western history, typically characterized by a keen sense of change and exploration and also by an atmosphere of personal, political and social insecurity. The eagerness with which developments in the exploration of space are watched is only an illustration of the sense of new physical frontiers close at hand, the ferment of new ideas and the vast shifts in the individual's notion of the universe and his place in it, of his very nature, that mark our time like those of Leonardo, Columbus, Magellan and Vasco de Gama. There are the same new and violent and little-understood demands of political and social organization and the same intense need for vigorous and imaginative leadership in every field.

---

* Carnegie Institution of Washington. The Report of the President, 1959–1960. Pp. xiii–lxxiv. (Reprinted from *Carnegie Institution of Washington Year Book*, 59.) (Washington, D.C.: Carnegie Institution of Washington, 1960.)

Dr. Haskins does not omit to point out that some of the changes with which we are concerned so vastly exceed those that occupied other ages as almost to differ in kind. The magnitude and variety of our sources of power, the capacity for essentially instantaneous communication have, for example, forced a major human adjustment on the West before it would accustom itself to this range and speed of communication, and new nations are called to make the same great orientation in a world which allows little time for major re-adjustments of international affairs. Further, new levels of human integration are demanded by the very pressure of population and the intricacy of modern life, and with the control, modulation and organization of the new sources of physical power calling for particular attention, an order of leadership and of excellence in every sphere greater than we have yet known is also demanded—a leadership of greater force, greater knowledge, greater understanding, and one more widely dispersed in every level of our society.

Here, in touching on science and leadership,' Dr. Haskins is concerned, not so much with the leadership of science itself, as in relation to the position of science within the framework of the character, the aspirations, and the contemporary needs of a nation, particularly the United States. He stresses the value placed on individual excellence, the dependence of the essential worth of life for the individual in a dedication larger than himself, and the way in which such total dedication spans the work-day world no less than the religious realms. Reasoning thus, the supreme importance which science attaches to the individual leads him to regard science as one of the spiritual factors in a democracy, closely resembling in its own society that of a democracy, deeply motivated by an ethic at once basically religious in character and dedicated both to the supremacy of the individual and to that spirit of frontier uncomformity which is a pronounced and precious element in the American tradition.

Science, then, is one of the most precious spiritual and moral, as well as material, values in our society, and it serves us to-day in a particularly critical time, and nowhere more so than in its emphasis on the individual. Originality and independence, individual dissent, properly protected, are the very essence of our civilization ; and for science in its public function, the protection of the individual and his independence, the honour of free thought and free expression and the public welcome of dissent are all vital. To-day, however, they are threatened, not so much by formal oppression or suppression, or organized intolerance, as by more subtle and insidious factors—inattention, lassitude, hostility to innovation through misunderstanding of its nature and effect, especially the threat of simple, widespread, massive misunderstanding of the nature of the scientific way, its purpose and its indispensable place and part in our practical world and in our deepest philosophy and belief.

At this point Dr. Haskins returns to the analysis of the apparent dichotomy of the two cultures on which he touched in his previous presidential report, and, like Sir Cyril Hinshelwood, he regards the common factors that unite all the creative disciplines, be they artistic or humanistic, philosophical or scientific, as far deeper and more fundamental than the more obvious differences that distinguish them. Pointing out that in the earlier days of scientific effort, before the sheer weight of learning and evidence forced our modern specialization, many great figures frequently united the two fields, he stresses the essential identity, at their most general level, of the characteristics and objectives of the arts and of the sciences. Both are primarily concerned with the process of discovery itself, and with discerning the beauties of Nature. Both professionally excel in innovation, and take delight in the shapes of things, their patterns, lights and shades, and in the uncovering of hitherto unperceived relations. Both seek to cast their descriptions and discoveries in evocative and universal forms, and at a very profound level of understanding ; both take communicability and coherence, within the subject itself and with the audience, as the ultimate criterion of conceptual or of demonstrated truth. Nor is this all. Both take their very living being and draw their vitality from the joy of discovery, from the attaining of ends unknown when the work was begun, through means which are indeed partly or wholly unknown, but usually of technical difficulty. Both are deeply concerned with the underlying likeness between superficially unlike things ; with the equating of different aspects of the same phenomena; with uniting such apparently disparate aspects in common matrices; with the generalizations which follow painstakingly minute analyses, with analogies and their testing. Typical of all the most creative and imaginative pursuits of man, of the life processes themselves, the arts and the humanities, quite as much as the natural sciences, must be truly consonant with our contemporary history; and as faithfully as they reflect their period, so they are reinforced by the societies that nourish them.

There are, of course, important differences between the disciplines of the arts and the humanities existing at another level, and these too must be fully recognized and understood. Dr. Haskins's penetrating analysis is particularly valuable here, and he does not suggest that it will be easy to heal the rifts that have grown between the kingdoms of the humanities and the natural sciences, between the bodies of thought that they comprehend and the men who are their practitioners. That the fundamental similarities, the bonds of common purpose and of common tasks unite them more strongly and more deeply than these differences are plain to see; and they offer foundations on which to build, to bridge the gaps of understanding and of sympathy, to undo the damage and eliminate potential dangers that arise. But this will not be the easier because the rifts should not exist.

First, Dr. Haskins suggests, in art coherence is primarily internal, uniting the parts of one creation. In the natural sciences, however, it is in a sense external, at its best uniting in one theoretically coherent frame the fruits of many thinkers, whose work is often extremely disparate in character. Again, in art communication and communicability extend primarily between the creator of the work and his audience, at once his witness and his critic, and such communication comes primarily after the work itself is finished. In science, on the other hand, communication is at least as active during the progress of the work as after its completion, and in a very deep sense science is fundamentally a communal activity. Though the steps of innovation lie most often with the individual, truth for science more than ever before inheres in a composite fabric of evidence and interpretation, derived from a great body of communicating investigators examining Nature from a multitude of points of view.

Truth in our day, Dr. Haskins maintains, is a property of this common fabric of accepted knowledge shared among all the working scientists in a given field, and it is for this reason that the scientific community is in essence a world community, transcending the boundaries of nations. There is probably no close counterpart to this aspect of the scientific effort within the arts; but on the other hand, while in the arts imagination alone may fix the final limits of shared experience, in science, despite the indispensable assistance given by imagination in discerning those limits and in reaching the goals they define, the limits themselves are determined by the concrete evidences of verification and therefore, ultimately, of the human senses. Nevertheless, Dr. Haskins does not omit to point out that this ultimate criterion is itself relative, joining the observer and his environment in a system from which he can never be isolated.

From this communal characteristic of science many striking contrasts between its operating modes and those of the arts are derived. One is the strong tendency to specialize, which is so characteristic of the natural sciences to-day. Dr. Haskins recognizes that specialization is essential to scientific progress; but he has wise words about the dangers which attend the consequent fragmentation of science and the need to deal adequately with the problem of communication in order that the rich opportunities which are offered by the borderlands of two or more disciplines may be explored and seized.

In this presidential report, Dr. Haskins thus ranges imaginatively and suggestively over a wide field, recognizing alike the intellectual and spiritual value of science for its own sake, its suggestive affinities with and differences from the arts and humanities, and its pragmatic importance as the architect of great material power. His review is notable for the dignity as well as the range of its thought. Dr. Haskins recognizes that it is imperative that we understand the nature and the needs of the scientific way, and comprehend the dangers that may menace it; and his review is commended to the attention of all concerned with the organization of Britain's scientific effort or the shaping of her educational institutions to meet the needs of to-day and to-morrow. They will indeed find here no blue-prints or prescriptions for policy, but they may gather some penetrating insights to the nature and needs of our larger society, some vision to inspire the leadership needed in a critical period of history the challenge of which for the future may well be, as Dr. Haskins suggests, without parallel in human experience.

PLANT MORPHOGENESIS

Plant Morphogenesis

By Prof. Edmund W. Sinnott. (McGraw-Hill Publications in the Botanical Sciences.) Pp. x+550. (New York: McGraw-Hill Book Company, Inc.; London: McGraw-Hill Publishing Company, Ltd., 1960.) 97*s*.

DURING the past twenty years, a not inconsiderable number of books and reports of symposia have been concerned with morphogenesis in plants, either from some particular point of view or in its more general aspects. The subject is in no sense new, though at different times it has been described by different names. During the nineteenth century, Naegeli, Hofmeister, Sachs, Vöchting and many others were deeply involved in the problems of the inception and development of form and structure in plants; and the present century has had some notable exponents of the subject, which now has many adherents. Yet there is justice in Prof. Sinnott's statement that few, if any, attempts have been made to treat the subject as a whole and that no extensive synthesis of its content has been undertaken. Now, after forty years as a research worker in this field, he has written the book under review—assuredly a gigantic and formidable undertaking. From the outset it is evident that he is fully aware that, in attempting a comprehensive treatment of this large subject, he is unlikely to please all his readers and that, at every point, he lays himself open to the criticisms of those with special knowledge of some particular aspect. Nevertheless, works of synthesis must be attempted by those who possess the necessary outlook, knowledge and courage, if botanical science is to retain some semblance of coherence. For this reason alone, Prof. Sinnott's book seems likely to have an important impact on botanical science.

The author has set about his task by introducing some idea of what is involved in morphogenesis, rightly emphasizing the importance of the central, if enigmatic, concept of biological organization; for at every developmental level at which there is visible expression of organic form there is evidence of unity and harmony of development, indicating the existence of co-ordinations and other inner relationships in which both genetical and extrinsic factors are involved. Part 1 of the book then begins with a consideration of growth in general, its cellular basis, and the histological constitution of apical and other meristems. In this section, also, the author has dealt, adequately and lucidly, though rather briefly, with experimental studies which have contributed to our understanding of the constitution and morphogenetic function of apical meristems. In view of the wealth of interesting illustration of apical meristems, contributed by investigators all over the world, it seems a pity, especially for student readers, that this section is so scantily illustrated.

In Part 2, the author has considered the phenomena of morphogenesis, dealing with such topics as correlation, polarity, symmetry (including the phenomena of phyllotaxis), differentiation, regeneration, chimæras and abnormal growth. This section, in short, relates to much that has been of acute interest to physiologists and others over many decades, but particularly during the more recent period. For the general botanist, and for the student of morphogenesis in particular, this section contains much fascinating and well-documented information, set forth in a simple and readable fashion.

In Part 3, the numerous and diverse factors in morphogenesis are considered, including light, water relationships, temperature, other physical factors, chemical factors in general and growth substances in particular, and of course, genetical factors. It is in this section, where a vast amount of specialized information, of very different kinds, has had to be considered and compressed into a relatively small number of pages, that the author is probably most vulnerable. He has, indeed, undertaken a task which, in view of the contemporary output of botanical research, is more appropriate to a team than to an individual. Nevertheless, he has made available to the reader a general survey of many of the factors that are involved in morphogenetic processes, and he has constantly reminded him that these factors never work in isolation: on the contrary, it is to their interaction that many of the distinctive features of living entities must be attributed.

The final chapter of the book deals with organization, obviously a topic of paramount importance in biology, but one on which few botanists have attempted to put pen to paper. However elusive and enigmatic this concept may be, its importance cannot be over-estimated. After all, some attempt to understand what constitutes organization is implicit in the aims and outlook of all those who undertake serious investigations of morphogenesis. In this chapter, which is the essence and summation of his book, Prof. Sinnott recognizes that several morphogenetic 'components' are of very wide occurrence in the plant kingdom and contribute fundamentally to the general phenomenon of organization. These components—polarity, differential gradients, symmetry and spirality—are also described as "inherent or basic tendencies". They "seem to be distinct characteristics and may have different bases in protoplasm. . . . All of them, or their rudiments, seem to be present in all plants. They provide the basic ingredients, so to speak, out of which the developmental norm is produced. Just what a specific norm will be depends on the interaction between these inherent protoplasmic traits and two other factors: the genetic constitution of the individual and the environment in which it develops". The genes, in a particular environment, act on these protoplasmic traits to produce the specific form of the organism. But, as the author points out, how genes control developmental relationships, and thus the production of organic form, is unexplored.

The author also discusses what gives unity and self-regulatory character to an organism, and concludes that ontogenetic unity, and also regenerative developments, are not so much due to the unchanging genetic constitution but to the "developmental norm, immanent in the organism from the first and often reached over different routes". In brief, the elucidation of self-regulatory, 'normative development' is regarded as the central problem in the phenomenon of organization. The difficulty of the task is indicated by the numerous workers, cited by the author, who have ventured into this field of inquiry. A synthesis of evidence from many different sources is, of course, essential, but what will come out of the attempted synthesis will, in the author's view, largely depend on the attitude and philosophic outlook of the investigator. After discussing some of the more interesting and relevant ideas that have been proposed to account for biological organization, Prof. Sinnott concludes quite simply by saying that, after all, we still have no idea of what the underlying physical basis really is. But, as is proper to one who has undertaken such an onerous task as the present book, he is not unhopeful, though he recognizes that the phenomenon of self-regulatory organization may well involve principles as yet undiscovered. These may prove to be distinctively biological and different from those at present available from the physical sciences—a conclusion which is not unlike that of some other contemporary exponents. This is a stimulating chapter, and although much of the ground that it covers is not new, it is, nevertheless, individualistic and provocative and is likely to create much new interest and discussion.

In an extensive work such as this it would be surprising if there were not grounds for criticism, of factual detail, emphasis, treatment, and so on. Some readers will no doubt find the text somewhat thin in places, for example, the treatment of embryogenesis. In the present review it is not necessary to enter into a discussion of such details. But there can be no doubt that Prof. Sinnott has produced an important and impressive book, one which seems likely to stimulate and hold its place in university teaching and research for many years to come.

C. W. WARDLAW

MODERN ARMAMENTARIUM OF THERAPEUTICS

Medicinal Chemistry

Edited by Prof. Alfred Burger. Second edition. Pp. xiii+1243. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1960.) 280*s*.

IT is the usual procedure that second editions of successful books are corrected versions of the original opus, with certain parts brought up to date. Prof. Alfred Burger must have faced a difficult decision when changing his role from that of sole author of the first edition to that of editor-in-chief and part-author of the new volume, at the same time re-organizing its contents. With due regard to his achievement as represented by the older version, it was a wise decision—because he has assembled around him an impressive list of contributors, holding industrial as well as academic or Government positions, but still reserving for himself the lion's share. The choice of one instead of two volumes is perhaps less fortunate as the weight of the present tome prevents one from reading certain chapters with leisure after working hours. It is also a matter for slight criticism that he selected an all-American team, which, in spite of the high standing of the individual scientists, diminishes somewhat the threads of international connexions so closely interwoven with successful research.

That does not mean that the writers on various aspects of medicinal chemistry (which, as Burger points out, can be equated with pharmaceutical chemistry and represents one very important chapter of applied organic chemistry plus pharmacology, experimental pathology and microbiology, etc.) have neglected results not originating with efforts in the United States. But with the best of intentions for fair play, a certain 'parochial' note creeps in sometimes, the reference to proprietary names, to major illnesses and pharmaceutical sales, to cholinergic instead of parasympathomimetics and to adrenergic instead of sympathomimetic drugs (Dale clearly reserved the expressions 'cholinergic' and 'adrenergic' for structures and nerves of the autonomic system). It should be said that only a very close study of the book discloses these relatively unimportant shortcomings; the overall impression is favourable, with the consequence that this volume will acquire many friends in many countries.

If a few suggestions for the third edition may be added, these are examples: an overall division into symptomatic, etiotropic (chemotherapeutic) remedies and drugs for restitutional therapy could have been given as a table and used as chapter-grouping; the historical table (2-11) has a few omissions, for example, Kennaway's name against experimental carcinogenesis and Todd's name against thiamine synthesis; action mechanism of central nervous system depressors ignores McIlwain's most vital contributions, and the difference between curare and curareform drugs and the methonium compounds is not sufficiently brought out; it is also a pity that little is said about the cannabinols mentioned only under "Analeptics", and very briefly under "Drugs for Hyperkinetic Disorders", although the synthetic derivatives represent an interesting and early group of psychopharmacological agents (formula 23-X and the name 'cannabadiol' are incorrect). Finally, an alphabetical list of authors after the subject index would have helped enormously if looking for specific references.

As said in my review of the first edition (*Research*, 4, 438; 1951) it is easy to criticize, but a very difficult task to write, such a book, and I should add even more so to edit the new version with its many improvements and attractive features.

F. BERGEL

BIRDS AND MEN IN BORNEO

The Birds of Borneo

By Bertram E. Smythies. With special chapters by Tom Harrisson, Lord Medway, and J. D. Freeman. Pp. xvi+562+99 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1960.) 84*s*. net.

THIS is a very unusual bird book. The main body of the work (about 460 pages) consists of a detailed systematic account of all the 549 species of birds that have been found in Borneo. It is written with the competence and thoroughness that distinguishes the author's previous volume on the birds of Burma. The articles dealing with the regular members of the fauna give the world distribution and Bornean status of each species, an adequate description, and discuss the habits, voice, food, and nest and eggs; the irregular visitors and casuals are treated more briefly. Appendixes contain the history of Bornean ornithology, an exhaustive bibliography, indexes of place-names, and of Malay and Iban names; and there is a large folding topographical sketch-map of Borneo. The illustrations, which are of very high quality, consist of 29 photographic plates and 50 plates in colour depicting 434 species from drawings by Commander A. M. Hughes.

But it is the hundred pages that precede this excellent treatise that put this book in a class apart. The first three chapters comprise an introduction, a topographical description of Borneo, with a discussion of the varied habitats that the island provides, and an account of bird migration in Borneo. These are followed by four chapters of ornitho-anthropology by Mr. Tom Harrisson, Lord Medway, and Dr. J. D. Freeman which are of the greatest interest. Harrisson says: "There is probably no other part of the world where birds and men are more intimately mixed than in Borneo", and goes on to discuss "Man v. Bird v. Man", "Man-Bird double-thinking" and many other matters, from Borneo's wild men and their bird values to hornbill ivory (more precious than jade), feather jewellery, and birds and the human stomach. This chapter overflows with information and ideas, and though it would gain in clarity with fewer parentheses it would lose much of its characteristic style. Lord Medway's chapter gives a fascinating account of the cave swiftlets, the saliva-built nests of which are the edible birds' nests of commerce, and which echo-navigate in the darkness of the caves where millions congregate to breed. Harrisson remarks that Governments "by some complicated zoo-geology, claim the guano as a mineral and allow extraction (for fertilizer) under licence. Thus what comes out of the swiftlets' mouth as spit is succinctly dissociated from what comes out of the other end". The chapters by Dr. Freeman cover Iban augury, "the interpretation of divine revelation as it is believed to be manifested in the behaviour of certain sacred birds", and the hornbill ritual of the Iban of Sarawak. The first part of the book is illustrated with 19 plates, two of them in colour.

The publishers are to be congratulated on the excellent standard of production, worthy of this valuable addition to ornithological literature.

L. Harrison Matthews

VEGETATION AND FOREST TREES OF GHANA

Synecology and Silviculture in Ghana

By Dr. Charles J. Taylor. Pp. xi+418+120 plates. (Edinburgh and London: Thomas Nelson and Sons, Ltd., 1960. Published on behalf of The University College of Ghana.) 100*s*. net.

THE title of this book is unfortunate, despite its euphony, because to many potential readers it will suggest something penetrating far deeper into ecological phenomena and sylvicultural practice than was ever intended, and so leave them unjustifiably disappointed. The book consists chiefly of descriptions and notes on about 160 economically or ecologically important tree-species of the Ghana rain forest. About half the letterpress devoted to each species describes its visible features; the remainder, its habitat, distribution, phenology, and, where appropriate, its sylvicultural behaviour or treatment, and its seed and seedling. The descriptions are aided by numerous photographs and drawings which doubtless account for the high cost of the book. The line drawings are less finished than many which have been published, but most of them are adequate. It is a pity that some of the drawings of seedlings are the least satisfactory (for example, *Guarea cedrata, Pterygota macrocarpa*), for it is sometimes impossible to tell from them what shape the cotyledons are, and in particular whether they are thin or fleshy. The photographs form a very useful collection, and represent an amount of work which only those with experience of photography in rain forest will appreciate.

This systematic part, which forms about three-quarters of the whole, is prefaced by a brief outline of the history, topography, soils, climate and vegetation of Ghana, excellent in its way, but somewhat disjointed and with little relevance to what follows. This general matter will be useful—but doubtfully worth £5—to students of geography or botany. Dr. Taylor writes with generally commendable simplicity, though occasionally his language becomes a little too simple for accuracy, and some ecological terms (for example, plagiosere), are used incorrectly.

The style and content of the book show that it is intended for use chiefly in Ghana. Here the book will undoubtedly be an invaluable companion to ecologists and foresters; elsewhere in the West African rain forest it will be useful chiefly for its descriptions of 'slash' and other field characters, and of seedlings. Although it is not a flora, one of its principal uses will undoubtedly be for naming trees, for which it could be greatly improved by (*a*) referring in the text to the plates, (*b*) by stressing (for example, by italics) the most useful diagnostic characters, and (*c*) by adding some kind of key or summary-table which would help the beginner in knowing which family to consult.

The book is well produced and contains very few misprints.

THE CONVOLUTION TRANSFORM

Operational Calculus

By Prof. Jan Mikusiński. (International Series of Monographs on Pure and Applied Mathematics, Vol. 8.) Pp. 495. (London and New York: Pergamon Press; Warszawa: Panstwowe Wydawnictwo Naukowe, 1959.) 100*s*. net.

THERE are many ways of developing the transform calculus, all more or less formally equivalent. Mikusiński's starting point is somewhat uncommon: the convolution of two functions $a(t), b(t)$ is

$$\int_0^t a(t-u)\, b(u)\, du$$

which he writes as ab. Since

$$ab + ac = a(b+c),\quad ab = ba,\quad (ab)c = a(bc)$$

while ab is not identically zero unless $a(t)$ or $b(t)$ is identically zero (Titchmarsh's theorem), we have an algebraic structure which is similar to Volterra's algebra of composition, and a formulation which is equivalent to Heaviside's 'algebrization' of functional operations. There are some differences, for convolutions exist over the class of continuous functions, whereas the existence of the Laplace transform requires an order condition. There is also an early difficulty, for if a and b are constants, does ab mean their arithmetic product or their convolution abt? Volterra used a special notation a^*b^*, while Mikusiński gets over the ambiguity by distinguishing the functional form $\{f(t)\}$ from the functional value $f(t)$; once one gets used to this, the calculus is simple and effective, though the reader will find it necessary at a later page to pay special attention to the introduction of operational functions.

There are plenty of applications, to electric circuits, statics of beams, vibrations, the heat and cable equations, and a good supply of exercises. Those who know the earlier Polish, Russian or German versions will appreciate the appendix of a hundred pages in the English edition, for this not only carries certain applications further, and provides on the theoretical side a link with Banach spaces, but, even more usefully, adds details to complete certain proofs which are only sketched in the main text. While perhaps the young student should stick to one line of approach to the operational calculus, his teacher should select such a line for him from a knowledge of alternatives; Mikusiński's book provides a very pleasant account, worth studying for its own sake and for comparison with more familiar formulations of this calculus.

T. A. A. Broadbent

BETTER OPPORTUNITIES IN TECHNICAL EDUCATION

By Dr. P. F. R. VENABLES

Principal, College of Advanced Technology, Birmingham

THE second White Paper, with this encouraging title, was published in January*, nearly five years after the first White Paper on Technical Education. Much has happened in this intervening period, both in implementing the first and in determining the character of the second White Paper, and they must perforce be considered together.

The policy of the first White Paper was to establish a new four-tier structure in technical education, of local and area colleges, then regional colleges and, at the apex, the colleges of advanced technology, which were to be the main means of producing the much-needed technologists. The second White Paper directly affects the work and development of the first three levels of colleges because it contains proposals for a major reconstruction of the system of courses for technicians, craftsmen and operatives provided by them. Of the factors which have prompted these proposals, three have been dominant: The first is the need to supply more technical education for the greatly increased number of young people soon coming into employment; secondly, the need to smooth the transition from school to college; and thirdly, the need to reduce greatly the wastage in part-time courses made evident by the Crowther Report. The question is whether the proposals, and the means to implement them, are commensurate with the needs of the times.

The main proposals are summarized as follows:

(1) Students should start at a technical college immediately after leaving school. Preliminary courses in evening institutes should be discontinued.

(2) More care should be taken in the selection of students for courses. Colleges should experiment with full-time induction courses and with tutorials.

(3) The courses will include: (*a*) National Certificate and Diploma courses for students aiming to become at least high-grade technicians; (*b*) Technician courses devised specifically for particular industries; (*c*) Craft courses; (*d*) Courses for operatives.

(4) Ordinary National Certificate courses will last two, instead of three, years. The standards of entry will be raised either by insisting on four General Certificate of Education (Ordinary Level) subjects, or by passing the sessional examinations of the new general courses which will be introduced. These general courses may lead also to technician courses.

(5) Craft courses will be modified in various ways, for example, by broadening their content, and in replacing City and Guilds Intermediate by Craft Certificates; and courses for operatives should be vigorously developed.

(6) More time should be provided under day-release schemes by extending the session to the county college year of 330 hr. per annum, as specified in the 1944 Education Act, and the gain in time should be spent on general education. No student should have to rely wholly on evening study.

(7) Sandwich courses (especially for technicians) and block-release courses should be increasingly developed.

The proposals include no novelties—day-release courses are at least forty years old, sandwich courses nearly sixty years old, the county college idea more than forty years old, though the much fewer courses for operatives and block-release courses are more recent in origin. The White Paper, therefore, is to be regarded as extending the application of well-established ideas and increasing the support given to them, especially from industry. In its summary, the White Paper gives too optimistic an impression in stating that "About half a million students are attending the courses at present, and the Government look forward to a big increase in their number". A realistic basis for judging the present position and future tasks is to compare two facts: while the numbers in part-time day-release courses increased tenfold from 1938–39 to 1958–59, the numbers of students of 'County College age' still only reach about 17 per cent of the total age group (15, 16, 17 years) in employment. In short, after a ten-fold expansion over so long a time, we still have about six times as far to go 'on a voluntary basis' to include all who should be in county colleges: and by no means all the 17 per cent will be affected by this White Paper.

Significant though they are in mitigating the rigours of the part-time route, the proposals should, therefore, not be allowed to obscure the far greater advantages that would accrue to the whole age group were the recommendations of the Crowther Report implemented of both raising the school-leaving age and establishing county colleges. The White Paper admits that: "In a system of voluntary part-time courses there are limits to what can be done". With more candour, it would have inserted the word 'severe' before 'limits', for the awkward unpalatable problems remain, namely, those described by the Crowther Report as "The Need for Time" and 'The Need for Breadth". The severe limits apply both to the content of the courses and to the support they are likely to attract from industry, especially among the 73·5 per cent of 56,000 manufacturing firms each of which has less than a hundred employees.

The White Paper can, of course, only suggest a general pattern within which the many bodies responsible for the actual planning and provision of courses must do their work. Many hundreds of existing courses will need to be modified, and many new ones developed, especially for technicians and operatives. This essential task is being tackled with a commendable sense of urgency by the City and

---

Guilds of London Institute, the Regional Examining Unions, the Joint Committees and so on, and there is little doubt that these long-standing partnerships in technical education will achieve what is possible within the limited time-tables set by the proposals.

It is difficult to be sanguine as to whether the other means required are commensurate with the needs of the next decade. The first White Paper gladdened the hearts of those engaged in technical education by definitely allocating £97 million for the expansion it envisaged, and another £45 million were added in 1959, whereas no estimate of additional cost is given in the second White Paper. It might well be argued that the original target of doubling the then day-release figure of 330,000 by the mid 1960's is allowed for, or nearly so, in the building programme covered by the foregoing sums. Perhaps it is for this reason that the White Paper expresses the opinion on the cost that "relatively to the total expenditure on technical education this should be small"; and this despite the fact that the number of teachers engaged in technical education is likely at least to double in the next ten years without any effects of this White Paper being taken into account. Furthermore, the White Paper envisages a big increase in half a million students, but should this merely be up to the original 660,000, especially when attendance at evening institute courses is to be discontinued and block-release and sandwich courses are to be increased. In the latter types of courses, two students will use the space (and teaching strength) of five part-time day students with consequent increase in expenditure. The effect will be even greater in providing workshops in block-release and sandwich courses with a high proportion of practical work. In view of the sentence about expenditure quoted above, a sceptic, knowing the rearguard actions fought in the history of technical education, might justifiably conclude that the effect of the White Paper will prove to be no more than a desirable reduction of the rigours of an outmoded part-time route, supplemented by some sandwich courses, rather than the rapid replacement of it up to 18 years of age by technical education in full-time and sandwich courses. If the latter were strongly pressed forward with really adequate means instead of just bringing the past up to date, then a notable advance to meet the rising demands of the next decade would be achieved.

GOLDEN JUBILEE OF THE BIOCHEMICAL SOCIETY

By Dr. P. N. CAMPBELL and Dr. W. J. WHELAN

Honorary Secretaries

THE first meeting of the Biochemical Club was held at University College, London, on March 4, 1911. After the Club had acquired *The Biochemical Journal* in 1913 it changed its name to the Biochemical Society. This week, therefore, sees the fiftieth anniversary of the foundation of a Society instituted solely for the advancement of the science of biochemistry. We are glad to have the opportunity to survey, briefly, the past history of the Society and to look to the future.

Early Days

On reading the *History* of the Society, prepared by R. H. A. Plimmer in 1949, one is conscious of the fact that, although the Society has grown enormously, its character has altered very little. It was from the start decided that the practice of the Physiological Society should be adopted and that the Society should meet at various laboratories. During the first year, eight meetings were held, and by the time of the first annual general meeting there were 132 members. The next year was taken up with the negotiations for the purchase of the *Journal* from Benjamin Moore, the first professor of biochemistry in Great Britain, who had founded it in 1906. A poll of the members in 1912 resulted in the decision to make membership involve compulsory subscription to the *Journal*, and so the subscription was raised from 10*s*. 6*d*. to 25*s*. per annum. The Cambridge University Press has been responsible for printing and publishing the *Journal* since 1913.

In the first few years the Society made a small profit, but after the First World War the cost of publication rose and grants were received from the Royal Society and other sources. At this stage the subscription was raised, first to 35*s*. and then to 42*s*. It was many years later, in 1953, that the last change was made to 70*s*. The present sound financial state of the Society, which does not depend on any form of subsidy, is due in the first place to J. A. Gardner, who served as honorary treasurer during 1913–43.

Personalities within the Society

The early years of the Society were marked by long periods of devoted service on the part of its officers. Such extended service would not be possible to-day because of the size of the Society, which now finds it necessary to rent offices and to employ a professional staff to organize its affairs. These are only very recent developments, and for the first forty years of its existence the only premises the Society could be said to have were the offices and laboratories of its honorary officers. J. A. Gardner's long service as treasurer was matched by A. Harden's editorship of the Society's *Journal* during 1913–37.

The first chairman of the Society's committee was F. Gowland Hopkins, and his services to biochemistry were commemorated by the Society in 1958 by the endowment of the Sir Frederick Gowland Hopkins Memorial Lecture. The third of these lectures will be given by Sir Hans Krebs at the Royal Institution on March 28. The Society also shows its gratitude for outstanding service by the election of honorary members, and those so elected have been W. D. Halliburton (1923), A. Harden (1938), Sir Frederick Gowland Hopkins and R. H. A. Plimmer (1943), Sir Charles Martin (1951), Sir Henry Dale (1958) and Sir Rudolph Peters (1959).

Membership

Membership of the Society is open to all those who are interested in biochemistry, and is not confined to those who reside in the United Kingdom. In fact, more than 30 per cent of the present members live overseas. The total membership passed the 1,000 mark in 1944, and at the present figure of 3,000 has doubled in the past ten years. This means that the Society is the largest of its kind in the world.

Role in International Biochemistry

Since the Society's membership is world-wide, it is natural that it should be interested in international relations among biochemists. In 1948, the Society sent out an inquiry concerning the desirability of holding an international congress of biochemistry. The response was so favourable that the Society took the initiative and organized the first International Congress of Biochemistry, held in Cambridge in August 1949. At this time there was no international union of biochemistry, and the first Congress had the backing of the International Union of Chemistry. In this year (1961), when we look forward to attending the fifth of these congresses, to be held in Moscow in August, it is with pleasure that we recall the initiative of those who worked hard for the first congress.

After the success of the first congress, strenuous efforts were made to found an International Union of Biochemistry recognized by the International Council of Scientific Unions. These efforts were eventually successful in August 1955.

Although these large international congresses have much merit, there is also a case for holding smaller meetings on a more limited scale. The joint meetings which the Society holds with its sister societies in Europe come into this category. It has now become the custom to hold one of these meetings during the years when there is no international congress. Through these meetings, biochemists in Great Britain are able to make personal contacts with those in Europe. For our part, we offer a special invitation to European biochemists to attend the summer meeting of the Society which is held each year, either in Oxford or in Cambridge.

Meetings

The policy of holding meetings for the presentation of original contributions has changed very little since the early days of the Society. A member has the right, and is indeed encouraged, to present the results of his work before a meeting of other members of the Society. This is an important aspect of the work of the Society, and last year 260 papers were presented in this way. It is also useful, however, occasionally to discuss some particular aspect of the subject at greater length, and it was with this in mind that a series of symposia were initiated in 1947, the proceedings of which are published. So far twenty of these symposia have been held.

In addition to the two types of meeting already described, colloquia are held at which work on a particular research project is discussed. This type of meeting is normally held in conjunction with an ordinary meeting of the Society, and serves to direct attention to the work of the department being visited. The number of scientific meetings of all types reaches 404 at the fiftieth anniversary meeting.

Publications

One of the most important activities of the Society is the publication of *The Biochemical Journal*, in which are to be found many papers now regarded as classical landmarks in the development of the subject. Prof. Moore founded his *Journal* in 1906, because of his desire that contributions should be published as submitted without criticism or editorial suggestions. Much of his reluctance in parting with the *Journal* to the Society was due to his fear that this policy would be changed by the Society, and it cannot be denied that his fears were well founded. In fact, ever since the acquisition of the *Journal* in 1913 the editorial policy has been strict. This policy has helped to establish a tradition of care and proficiency in biochemical laboratories.

Within the high standard set for the acceptance of papers for the *Journal*, the policy of the Society is for the *Journal* to publish all papers submitted for publication which come within the subject of biochemistry. Authors do not have to be members of the Society. With the expansion of the subject this policy has led to an enlargement of the *Journal*, so that while in 1950 1,279 pages were published, the corresponding figures for 1955 and 1960 were 2,112 and 2,510 pages respectively. The circulation has also expanded, and there are to-day more than three thousand subscribers who are not members. This means that the *Journal* probably has a larger total circulation than any other journal devoted entirely to biochemistry.

During 1957 the committee of the Society carefully considered whether the Society should expand its publishing activities. As a result of these discussions, it was decided that clinical biochemistry was not adequately covered, and the Society eventually became the joint owners with the Medical Research Society of *Clinical Science*. This journal is now published by the Cambridge University Press, and we look to its playing an increasing part in the work of clinical biochemists in Great Britain and overseas.

The Future

In considering the future it seems likely that the activities of the Society will expand most in directions which are concerned with the status of the subject in the universities. If biochemical research is to flourish in Britain, not only shall we need to attract the best students to the departments which now have a first-degree course in biochemistry, but also more departments must be created, both for teaching and research. Last year a booklet was published on *Careers in Biochemistry*, its aim being to provide full information on training, opportunities and prospects, for the benefit of potential students and their advisers. A series of discussions is being held on various aspects of the subject. For example, at a joint meeting with the British Association, in

September 1960, a symposium was held on "The Organization and Financing of Research in Biochemistry and Allied Sciences in Great Britain". The proceedings of this discussion have now been published by the Society. Later this year, at Oxford, it is planned to discuss the problems of teaching biochemistry to undergraduates.

Mention has already been made of the recent changes in the administration of the Society's affairs, largely a consequence of the rapid growth of its membership and of the *Journal* in the past ten years. The Society's healthy financial state has enabled these changes to take place smoothly, even to the renting of premises at the very high charges prevailing in central London. Not all the necessary changes can, however, be made so easily. The size of the audiences at the Society's symposia, held in London, makes it impossible any longer to hold these in many institutions which for long have acted as hosts. It is obvious that biochemistry is in a period of rapid expansion the limit of which is not yet set, and problems of accommodation will become increasingly acute. This is part of a wider problem, and the need to take action was realized after the War, with a proposal by the Government to establish a Science Centre from which learned societies could organize their affairs, centralize information, and conduct meetings. Unhappily the proposal never bore fruit; but its fulfilment would be one of the boldest moves in advancing science in Great Britain.

The main hope for the future must be that, in spite of the expanding activities of the Society, it will be able to remain reasonably informal so that there can be a ready exchange of ideas, both scientific and administrative. By this means it is hoped that the Biochemical Society will continue to play its part in the development of a still comparatively new and exciting science.

GENE EVOLUTION AND THE HÆMOGLOBINS

By PROF. VERNON M. INGRAM

Division of Biochemistry, Department of Biology, Massachusetts Institute of Technology,
Cambridge, Mass.

THE four types of polypeptide chain which go to make up the molecules of the three normal human hæmoglobins are believed to be controlled by four independent genes[1]. The following article is an attempt to discuss the chemical and genetic relationship between these chains from an evolutionary point of view; to a lesser extent, because much less is known, the hæmoglobins of other vertebrates will also be mentioned. It should be emphasized that the main purpose of this discussion, and of the evolutionary scheme to be proposed, is to provide a basis for the discussion of the evolution of genes in general and hæmoglobin genes in particular. Questions are raised which will, in part, be answered soon by the chemical work on vertebrate hæmoglobins which is now proceeding in various laboratories (see, for example, ref. 2).

The study of the chemistry of the human hæmoglobins has already provided evidence of the kind of phenotypic effects to be expected from gene mutations as, for example, in the known single amino-acid substitutions in the peptide chains of abnormal hæmoglobins[1]. It is on such changes in protein structure that the forces of natural selection are assumed to act. From the evolutionary and the practical point of view it is convenient to study a commonly occurring protein, such as hæmoglobin, which is found in all vertebrates. Hæmoglobin is not only accessible for chemical study but is also sure to have played an important part in vertebrate evolution, because of its vital physiological function as the carrier of oxygen.

Most of the discussion which follows will centre around the chemical findings in the human hæmoglobins, since they are by far the best studied of vertebrate hæmoglobins. However, the basic similarities in chemical structure between man's hæmoglobins and those of other mammals and lower vertebrates are very striking[3]. All known vertebrate hæmoglobins—except those of the lamprey and the hagfish—are built on the same molecular pattern: they consist of four polypeptide chains of roughly 17,000 molecular weight, with one hæm group each. The hæmoglobin of the lamprey is peculiar in consisting of a single polypeptide chain of molecular weight 17,000. The hagfish hæmoglobin appears to be similar, or possibly a dimer of 34,000 molecular weight[3].

The peptide chains in the other vertebrates are of two different types; for example, human adult hæmoglobin consists of two so-called α-chains and two β-chains. There is usually interaction between the four hæm groups in their reaction with molecular oxygen; in other words, a plot of the degree of oxygenation of the hæmoglobin molecules against the partial pressure of oxygen is sigmoid in shape[4]. This fact enhances enormously the physiological efficiency of the hæmoglobin molecule as our oxygen carrier[5], since it favours complete saturation with oxygen in the lungs and complete discharge in the tissues. This great similarity which characterizes most vertebrate hæmoglobins suggests that we are studying that aspect of the evolution of a particular protein molecule which is concerned with detailed development of an already well-defined molecule. It is true that the hæmoglobin quadruples its size during this evolution (if we include the lamprey hæmoglobin), but the change is due to the aggregation of four fairly similar protein sub-units (peptide chains), rather than to an actual lengthening of a molecule. In the evolutionary scheme to be discussed it is suggested that the increase in complexity, and in diversity, of the hæmoglobins is an illustration of a more general process of gene evolution which results in an increase of the number of genes.

Human Hæmoglobins

The following striking situation is found in the human hæmoglobins:

(1) The three normal human hæmoglobins all possess a common half-molecule which may be written $-\alpha_2{}^A$. This formulation indicates that this half-molecule unit is composed of two normal α-peptide chains as first described for normal adult hæmoglobin *A*. However, the other half of each of the three hæmoglobins consists of different types of peptide chain, β, γ or δ, one type for each hæmoglobin. All four chains are of roughly equal size with a chain molecular weight of about 17,000. These three hæmoglobins may be formulated as follows:

Adult = hæmoglobin A = $\alpha_2{}^A\beta_2{}^A$
Fœtal = hæmoglobin F = $\alpha_2{}^A\gamma_2{}^F$
Kunkel's minor component[6] = hæmoglobin A_2 = $\alpha_2{}^A\delta_2{}^{A_2}$

This list may have to be extended as the study of other minor hæmoglobins continues[7].

I postulate[1] that four genes are involved in the manufacture of these peptide chains, so that the *genotype* of a normal individual may be written as:

$$\alpha^A/\alpha^A,\ \beta^A/\beta^A,\ \gamma^F/\gamma^F,\ \delta^{A_2}/\delta^{A_2}.$$

In this view the products of the α-genes are common to all the human hæmoglobins.

(2) In total amino-acid composition[8] the four types of chains compare as follows:

α^A and β^A — differ in perhaps 21 out of nearly 140 amino-acids
γ^F and β^A — differ in perhaps 23 out of nearly 140 amino-acids
δ^{A_2} and β^A — differ in less than 10 amino-acids.

In addition, γ^F is the only one of these chains to contain the amino-acid *iso*leucine—four residues per chain.

(3) The α^A-chain begins with the amino-acid sequence[7] Val-Leu- . . . ; the β^A-chain and the δ^{A_2}-chain begin with Val-His-Leu . . . . The γ^F-chain begins with the sequence Gly-His-Phe-, which although different from the β-chain shows a clear affinity in the type of amino-acid with the beginning of the β^A-chain. In both cases, the first amino-acid is neutral and aliphatic, the second is the basic amino-acid histidine, and the third has a non-polar side-chain.

The peptide chain beginning with the Val-Leu-sequence (α-chain) has a counterpart[3] not only in all known mammalian hæmoglobins but also in the hæmoglobins of all the lower vertebrates so far examined, except for the hæmoglobin of the lamprey. This is not to say that the Val-Leu- chains of other animals resemble the human chain precisely, but rather that there might be a strong 'family resemblance'. It is of interest to attempt to explain the repeated occurrence and strange similarity of the Val-Leu- (the α) chain in the vertebrates.

The following postulates are used in developing a scheme for the evolution of the hæmoglobin genes.

Postulate 1. Mutations of a gene result in either single or multiple amino-acid substitutions in the peptide chain which that gene controls, or inversions of part of the amino-acid sequence, or a combination of these possibilities. The new hæmoglobin peptide chains produced by such mutations are then either favoured or discarded in the course of natural selection.

Postulate 2. At several points in the course of evolution a gene for a particular hæmoglobin peptide chain has undergone *duplication*, followed by, or simultaneous with, translocation. The two initially equivalent genes have then evolved independently, governed by the selective pressure of their environment on their protein products. Such mechanisms have been previously postulated; for example, ref. 9. The role of gene duplication[9,10] in evolution has been discussed by Stephens[11]. His conclusion was that the case for duplication as an important factor in evolution was so far neither proved nor disproved.

It is of course equally possible to postulate the occurrence of chromosome duplication, with subsequent independent evolution of the initially identical chromosomes. Such a scheme would fit into the proposed hypothesis equally well.

It seems likely that α-, β- and γ-genes are located on different chromosomes, since they segregate independently, whereas β- and δ-genes appear to be linked[12].

Postulate 3. Once the α-chain, or rather the α_2-dimer, is required to fit precisely with at least two other dimers—β_2 and γ_2—the α-chain is no longer as free to be varied by mutation. It has become 'conservative' and its rate of evolution will be less than that of the other chains, as is perhaps seen in the persistence of the Val-Leu- beginning of the α-chain of the vertebrates.

In addition, one can postulate that mutations of the α-gene produce mutant α-chains which are more severely selected against in the later stages of evolution than are mutants of other chains. This is likely to be so, because in the later stages of evolution the α-chains participate in the formation of fœtal hæmoglobin, a vulnerable point in the life-cycle of the animal. It is a fact that mutants of the human α-chain never reach a high frequency of distribution, in contrast to some β-chain mutants, although we know of as many different kinds of α-chain mutants as of β-chain mutants.

Scheme for the Evolution of the Hæmoglobin Genes

We might suppose that originally the hæmoglobin molecule was rather like the present-day myoglobin molecule, that is, that it had a single peptide chain with a single hæm group, and that therefore it could not show hæm–hæm interaction. The size of this molecule might vary, but eventually it might be stabilized at a value of around 17,000 molecular weight.

At this stage of evolution, presumably earlier than the teleost fishes, the hæm protein inside the muscle cells is assumed to be the same as that in the circulation. The muscle hæm protein became myoglobin in the course of evolution; it retained a molecular weight of 17,000 and a complexity of only one hæm group and one peptide chain per molecule. It was, of course, still subject to mutational changes, as can be seen from the fact that its present-day amino-acid composition and sequence in a given animal often differs considerably from that of any of the analogous hæmoglobin chains[13]. For example, human myoglobin contains *iso*leucine, but no cysteine, whereas the reverse is true of human adult hæmoglobin.

On the other hand, one can foresee limits to the kind of mutations which would be tolerated. The X-ray studies of Kendrew[14] and of Perutz[15] show that the three-dimensional arrangement of chains in myoglobin and the hæmoglobin sub-units (also of

17,000 molecular weight) are remarkably similar, though not identical. This statement applies also to the two kinds of sub-units found in hæmoglobin itself. Presumably, mutational alterations in the course of evolution which would drastically affect the three-dimensional structure were not tolerated. Such considerations imply that the configuration of the peptide chains in myoglobin and hæmoglobin became stabilized early in evolutionary history, at least in its most important features.

During the evolution of the primitive hæmoglobin chain—provisionally called the 'α'-chain—there occurred a gene duplication followed or accompanied by translocation. From now on the two duplicate 'α'-chain genes could evolve independently—one to become the modern myoglobin gene, the other to become the α-chain gene of present-day hæmoglobin. Eventually, according to the scheme, the α-chain gene would evolve in such a way that its product, the α-chain, had the property of dimerization in solution to form α_2 molecules. Such a property would be favoured strongly, if it entailed, in addition, the possibility of hæm–hæm interaction between the two hæm groups of the new dimer molecule and therefore the possibility of more efficient oxygenation and deoxygenation. Once produced, such a mutation is unlikely to be lost in the further evolution of hæmoglobin.

At this stage, the sequence of the 'α'-chains is still variable within the dictates of structural requirements, since there is nothing yet to put additional restrictions on it.

We might next postulate that the genes of the α_2-chains duplicated again. After this gene duplication two types of dimer—α_2 and γ_2—would evolve side by side. Sooner or later, these chains would have evolved sufficiently to be able to form tetramers with even greater selective advantage because of the increased hæm–hæm interaction likely to be found in such tetramers. The characteristics of the genes responsible for the ability of the chains to form tetramers would certainly be fixed. This stage of hæmoglobin evolution seems to have been reached already in some teleost fishes, because they already possess a four-chain hæmoglobin[3].

The third gene duplication and translocation is pictured as occurring with the γ-chain gene, giving rise to a new γ-gene destined to evolve into the β-chain gene. At this gene duplication the property of forming tetramers is already firmly established. The new gene can develop along its own line to provide a hæmoglobin tetramer—$\alpha_2\beta_2$—particularly adapted for the adult body. On the other hand, the old γ-chain continues to develop and to provide half the molecule of the fœtal hæmoglobin ($\alpha_2\gamma_2$). It is the γ-chain gene, rather than the α-chain gene, which is said to duplicate here, because the γ-chain dimers, γ_2, have already the necessary complementariness for forming tetramers with α_2. This complementariness will be automatically a property of the product of the new gene. In addition, we shall see later that β- and γ-chains are more closely related to one another than either is to the α-chain. Therefore we might consider them to have diverged at a later stage.

At this point of evolution, three independent genes—α, β, γ—are assumed to be present, each one capable of forming chains which dimerize and which aggregate to the tetramers $\alpha_2\beta_2$ or $\alpha_2\gamma_2$. Hæm–hæm interaction is strongly present in the tetramers. Such a situation has an important effect on the further evolution of the α-chain. This chain, or rather its dimer, α_2, is required to fit with two different partners, β_2 and γ_2. As a result, less variation is allowed to the α-chain; it has become 'conservative'. Perhaps such conservation is in part responsible for the apparently universal presence of α-chains beginning with Val-Leu- in the hæmoglobins of the higher vertebrates. There is an alternative explanation for the apparently greater stability of the α-genes; this gene controls also the fœtal hæmoglobin and therefore may not undergo extensive mutational alterations, since the fœtus is a much more delicate organism. The very fact that any alteration in the α-chain gene, and therefore in the α-chain, seems to affect all types of hæmoglobin may be sufficient to explain the apparent 'conservatism'.

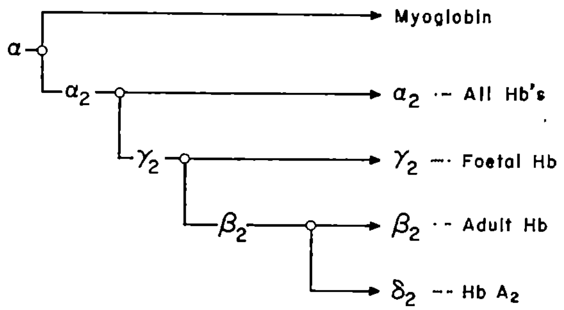

Fig. 1. Evolution of the hæmoglobin chains. The α-chain is the ancestral peptide chain. —○— indicates a point of gene duplication followed by translocation of the new gene

On the other hand, there is no *a priori* reason why different parts of a molecule as complex as a protein should develop at the same rate. The difference in apparent stability between the α-chain and the others could be no more than what would be expected as normal variation. It will be interesting to see just how similar the Val-Leu- chains of different vertebrates are.

At the fourth and last gene-duplication in the scheme we suppose that it is the β-gene which becomes duplicate, leading to the δ-chain genes controlling the δ-chains of hæmoglobin A_2. The origin of this δ-chain is placed near the end of the evolutionary scheme, because of its great chemical similarity to the β-chain[16]. Furthermore, the presence of a hæmoglobin A_2-like component seems to be confined to the higher primates[17]. In this view, hæmoglobin A_2 is a new hæmoglobin rather than an archaic one, as has often been supposed. It has been reported to have a higher affinity for oxygen[18] and perhaps it is a more efficient hæmoglobin, destined to replace eventually $\alpha_2\beta_2$ (ref. 19). Its proportion is certainly doubled in some thalassæmias[17], perhaps as a compensating mechanism. There is genetic evidence that the genes for δ- and for β-chains are linked[12], indicating perhaps that the process of translocation of the new δ-gene has not yet occurred.

Where does the lamprey fit into this scheme? One form, *Petromyzon planeri*, has two fœtal and two (different) adult hæmoglobins[20]. The molecular weight of the adult mixture is given as 17,000 (ref. 3). Perhaps these lamprey hæmoglobins are the result of an independent evolution scheme similar to the one discussed in the present article, but which has never included the mutations which led to the formation of dimers and tetramers. We might regard the lampreys as having branched off before or just after

the first gene duplication in the scheme of Fig. 1. Unfortunately, nothing seems to be known about the presence or absence of a separate myoglobin in the lampreys.

Discussion

The proposed scheme expresses a desire to explain the striking chemical similarity between α, β, γ and δ human hæmoglobin chains in terms of their evolution from a common precursor.

Braunitzer *et al.*[21] have published some preliminary findings of the amino-acid sequences in the first 30–40 positions of the human α- and β-chains (Table 1). Between the two sequences there is a strong 'family resemblance' of the degree expected for two gene products which have evolved independently, but from a common ancestor. Also Gratzer and Allison[8] have very recently discussed the possibility that the hæmoglobin chains might have evolved from a common ancestor.

It has been suggested to me that the four genes controlling the four chains might have evolved from four unrelated genes which originally controlled the synthesis of quite unrelated proteins; thus there would have been no increase in the total number of genes. By a process of parallel evolution—successive and independent mutations—each of these four genes eventually changed so that it made one of the hæmoglobin peptide chains. The last stages of evolution, when pairs of genes were involved in producing parts of a complex molecule, must then be called on to produce similarity in chemical structure and in configuration. It is easy to conceive of a selective mechanism which would favour changes in various members of a molecular aggregate, such that the members might fit together better. However, it is hard to think of such a mechanism also selecting for chemical and structural similarity of the monomers. In addition, the ability to dimerize would have to arise *de novo* four times, an unlikely situation.

Although we cannot at the moment completely reject the idea of parallel evolution of the four genes from unrelated genes, it is not a very palatable one. The similarity between the human α-, β-, γ- and δ-chains is so great: the C-terminus of the chains ends with the sequence -tyrosyl-histidine or -tyrosyl-arginine[16,22]; their common ability to incorporate an active hæm group; their similar folding and chain length[14,15]; absence of *iso*leucine in α, β and δ[8,16]; and so forth. Altogether, an evolution from a common ancestor is more attractive.

Chemical Evolutionary Relationship Between the Chains

How many mutational steps occurred between the original 'α'-gene and the present-day human α-gene? Or between the original 'α'-gene and the human β-gene? It is more meaningful, perhaps, to ask how many mutational events might separate the present-day human α- and β-genes. Out of 140 amino-acids, we know from the composition that approximately 20 are different. This gives a minimum of 20 mutations of the kind effecting single amino-acid substitutions.

It is believed that the evolution of the vertebrates began some 5 × 10^8 years ago. Let us assume a mean generation life of 5 years among the vertebrates, which implies some 10^8 generations for the evolution of vertebrate hæmoglobins. A generally acceptable rate[24] per generation is 10^{-5}–10^{-6}, which leads to a figure of 100–1,000 mutations in the evolutionary history of a vertebrate hæmoglobin. This figure, which is itself a minimum one, is very considerably higher than the (minimum) number of mutations which appear to distinguish α-chains from β-chains and α-chains from γ-chains.

The only conclusion which can be drawn from such a calculation is that a more than sufficient number of mutational events have passed in the history of the vertebrates to account for present-day differences between the various parts of the hæmoglobin molecule in the human species.

Comparison of the Fingerprints of the Human α-, β-, γ- and δ-Chains

Rather than deduce the chemical relationship between the chains from their amino-acid composition, it is better to compare their 'fingerprints'[24]. The two-dimensional maps, or fingerprints, of the tryptic peptides derived from each of these four peptide chains give at least a crude idea of the similarity and dissimilarity in their amino-acid sequences and hence of the closeness of the chemical relationship between them.

Human α-Chains and β- or γ-Chains

With the exception of peptide number 21 (ref. 25), all the peptides (some 14 for each chain) occupy different positions on the fingerprints[23] of α-chains compared with β- or γ-chains, or they can be distinguished by such methods as extended paper ionophoresis. They are therefore different in their amino-acid sequences. Peptide 22 is free lysine. It does not follow that the differing peptides of the α- and of the β- or γ-chains are totally altered. They could contain short amino-acid sequences in common[21]. In any event, the indications are that the amino-acid differences between the α- and the β- or γ- chains are distributed throughout their length.

The general comment might be made that there is a familial likeness between the distribution of peptides on the fingerprints of α-, β- and γ-chains. Surely this will reflect a structural relationship (Table 1). We would suppose that portions of their amino-acid sequences are common to all three, as is the tertiary structure of the two types of chain of horse hæmoglobin, which correspond to the human α- and β-chains.

Human β-Chains and γ-Chains

Apart from peptides number 21 (a pentapeptide) and 22 (free lysine), the following peptides[25] occupy very similar positions[22] and would be closely related, if not identical: peptides 12, 14, 15β, 19, 20β, 26. The number is an impressive proportion of the whole chain. If it is correct that these peptides are indeed identical in the β- and γ-chains, it would mean that perhaps 9 peptides out of some 14 are shared by the chains. Some of these peptides are quite long. Their position along the chains is not known, except that peptide 26 is the third one from the N-terminus[21]. These conclusions underline the chemical similarity between β- and γ-chains, which can also be deduced from their amino-acid compositions.

Human β-Chains and δ-Chains

The recent work of Stretton[16] has shown that the β-chains and the δ-chains are very closely similar in their fingerprints. In fact, out of a total of some 14 tryptic peptides, only 4 peptides are different; they are numbers 5, 12, 25 and 26. The similarity between other pairs of peptides from the β- and δ-chains has been ascertained much more carefully by amino-acid analysis than has so far been done with the γ-chains. Moreover, the differences between peptides 12, 25 and 26 from β- and from δ-chains have been shown to involve only 4 single amino-acid differences, for example, serine-threonine (in two places), threonine-asparagine, glutamic acid-alanine. These four single amino-acid differences, together with an unconfirmed fifth one, are so far the only ones definitely known between this pair of chains, each of which is some 140 residues long—a very close chemical similarity indeed.

Apart from the tryptic peptides of the α-, β-, γ- and δ-chains, there is in each case the trypsin resistant 'core' to be considered which amounts to rather more than a quarter of the chain. Here the differences between the chains are far from clear and cannot yet be usefully discussed, except to say that the 'cores' all appear to be similar.

Fingerprints of hæmoglobins from other mammals (ref. 2, and Muller, C. J., unpublished) are recognizable as 'hæmoglobin'. It will be interesting to compare the degree of similarity between the mammalian hæmoglobins on one hand with, say, chicken or teleost hæmoglobin.

Recently, Zuckerkandl[2] has shown that fingerprints of hæmoglobin from the gorilla and chimpanzee are indistinguishable from those of human hæmoglobin. A greater number of differing peptide spots are observed in the less closely related orang-utan and rhesus monkey. These extraordinarily interesting findings give added proof of the validity of using a chemical study of vertebrate hæmoglobins to discover evolutionary relationships.

Conclusion

It appears that a sufficient number of generations has passed since the beginning of vertebrate evolution to allow for the known or suspected number of mutations which separate the α-, β- and γ-chains of human hæmoglobin.

The similarity in the fingerprints between β- and γ-chains of human hæmoglobin supports the suggestion that these chains diverged from one another at a later stage in evolution than either from the α-chain gene.

The close similarity between β- and δ-chains gives weight to the idea that the δ-chains of hæmoglobin A_2 are a recent evolutionary development from the β-chains.

The suggestion is made that a single primitive myoglobin-like hæm protein is the evolutionary forerunner of all four types of peptide chain in the present-day human hæmoglobins, and of the corresponding peptide chains in other vertebrate hæmoglobins. Such a scheme involves an increase in the number of hæmoglobin genes from one to five by repeated gene duplication and translocations; the scheme may thus illustrate a general phenomenon in gene evolution.

I acknowledge the many stimulating discussions with Drs. C. Levinthal, S. E. Luria, C. Baglioni, A. O. W. Stretton, J. V. Neel and P. S. Gerald. I am also grateful to Drs. W. B. Gratzer and A. C. Allison for allowing me to read their review paper[3] before publication.

Two books have been particularly stimulating: J. B. S. Haldane, *The Biochemistry of Genetics*; and C. B. Anfinsen, *The Molecular Basis of Evolution*.

No serious attempt has been made to survey critically the literature on gene evolution or duplication. This is partly in order to present a clearer and more provocative hypothesis and partly because I do not feel qualified to evaluate the numerous contributions to that field. Recent experimental work on the animal hæmoglobins has been admirably summarized in the Gratzer and Allison article[3].

This work was supported by grants from the National Science Foundation and the National Institutes of Health, U.S. Public Health Service.

Note added in proof. Further work by G. Braunitzer and his colleagues (*Z. physiol. Chem.*, in the press) shows that the similarity of the α- and β-chains continues throughout these chains.

OBITUARY

Prof. J. T. Patterson

John Thomas Patterson, emeritus professor of zoology in the University of Texas, who died on December 4, 1960, at the age of eighty-two, will be remembered especially for his work on evolutionary genetics of *Drosophila*, published as a series of "Studies in the Genetics of Drosophila" by the University of Texas and culminating in a book, *Evolution in the Genus Drosophila* (1952), written in collaboration with Wilson S. Stone. Yet this great programme of work, involving the activities of numerous colleagues and graduate students, was initiated after he reached the age of sixty, in the evening of a long life devoted to biological teaching and research.

J. T. Patterson was born at Piqua, Ohio, on November 3, 1878. He received his bachelor of science degree from the College of Wooster in 1903 and his Ph.D. from the University of Chicago, where he was a student of C. O. Whitman, in 1908. He went to the University of Texas in Austin in 1908 as instructor in zoology, becoming adjunct professor in 1911, professor in 1913, 'distinguished professor' when this special rank was created in 1937, and emeritus professor on his retirement from teaching (but not from research) in 1955. He was one of the last of a great generation of Chicago Ph.D.'s in zoology that included such men as W. C. Allee, George Bartelmez, Carl Moore and Oscar Riddle.

When Patterson arrived at the University of Texas he found extremely primitive conditions in a frontier society. By his own efforts he built up the Department of Zoology, successively adding to the staff Carl Hartman, T. S. Painter and H. J. Muller. The bat-infested laboratory of the early years was replaced by the Biology Building in the 1920's and the magnificent Experimental Science Building in 1952. A total of thirty-one students received their M.A. degrees and twenty-nine their Ph.D.'s under Patterson's direction during the forty-eight years of his active teaching career in Texas. An extremely hard worker, he would arrive at the laboratory each morning about 6 a.m., spending the whole day in the big 'fly lab', at his microscope or talking with his students, with whom he had a very close personal relationship.

Patterson's early research was embryological. He studied the mechanism of development in the nine-banded armadillo, in which monozygotic quadruplets are invariably produced. From polyembryony in a mammal it was a natural step to studying polyembryony in the wasp *Paracopidosomopsis floridanus* Ashmead—a rolling name with which Patterson used to impress his elementary students, just as, in later years, he was able to silence an inquisitive Texas yokel by assuring him that his peculiar activities with an insect net were "collecting *Drosophila pseudoobscura* Frolova for my friend Professor Theodosius Dobzhansky".

Following on the discovery by Muller in 1927 of the mutagenic properties of X-rays, Patterson turned his attention to radiation genetics and worked on somatic mutation, mosaicism, gynandromorphs and the production of deletions and translocations by X-rays. But by the middle 1930's his active and restless mind seemed to have tired of these lines of work and for a while he devoted himself to building up a great collection of the flint artefacts of Texas and the neighbouring States, on which he published several papers. At last, in 1938, he found his greatest field of activity in the evolutionary genetics of *Drosophila*. This was a few years after Painter had shown that the salivary gland chromosomes of *Drosophila* could be used for an entirely new type of cytogenetic analysis which permitted a detailed comparison of the gene sequences of different species. The idea seems to have suddenly struck Patterson that he wanted to study, not just *Drosophila melanogaster*, or even the dozen or so other species that had been employed until then by a few geneticists, but the whole range of species belonging to this genus of flies—200, 500 or however many there might be (we now know there are at least a thousand).

Collecting expeditions were sent out to all parts of the United States and Mexico and later to Central America, Canada, the Caribbean and the Pacific area. Hundreds of species were brought back to the Texas laboratory, which became a living museum of *Drosophila* stocks which were subjected by Patterson and his students to a great variety of genetic techniques designed to elucidate their relationships. Painter's salivary gland technique was fully exploited in this work. The results were too voluminous to be published in the regular journals, so that they appeared in the now famous *University of Texas Publications*, generously distributed free to institutions and individuals throughout the world. Both taxonomy and genetics acquired new perspectives as a result of this work, for which Patterson received the Daniel Giraud Elliott Medal of the U.S. National Academy of Sciences in 1951 (he had been elected to the Academy in 1941). His studies of the *virilis* group of species will always remain classical examples of this kind of work.

Short of stature, direct and forthright in speech, Patterson impressed one with his energy, exuberance and whole-hearted dedication to his science. He never travelled outside North America and seldom left Texas after his middle years, when he still used to spend the summers with his family at Woods Hole and participate in the main stream of American biology. Thus he became something of a legendary personality even in his own lifetime to the many younger biologists of the eastern States and the west coast who had never met him. He had little use for intellectual subtleties, and his work deals almost entirely with the big problems open to a frontal attack. Although he made no single discovery comparable in importance with those of Muller and Painter, he has an assured place in the history of genetics and evolutionary biology. His influence on the development of the University where he taught and worked for more than half a century was very great.

M. J. D. White

NEWS and VIEWS

University College of North Staffordshire: Dr. H. M. Taylor, C.B.E.

DR. H. M. TAYLOR, secretary general of the Faculties in the University of Cambridge, has been appointed principal of the University College of North Staffordshire, Keele, from October 1, to succeed the late Sir George Barnes. He will bring to the service of Keele outstanding gifts of personality and a wide range of academic and administrative interests and experience. Dr. Taylor went up to Clare College, Cambridge, in 1928, after a distinguished undergraduate career at the University of Otago, New Zealand, and he continued to distinguish himself as undergraduate and research student in Cambridge. He graduated Ph.D. in 1933 and was elected Fellow of Clare in the same year. By 1939 he had made his mark in Cambridge as University lecturer in mathematics, secretary of the Faculty Board of Mathematics, director of studies in mathematics and steward of his College, and adjutant of the Officers' Training Corps. In these and many other fields he had given proof of great organizing ability, an orderly mind, industry, and a kindly and sympathetic personality.

After war service in the Army, as an instructor at the School of Artillery, Larkhill, Dr. Taylor returned to Cambridge in 1945 as University treasurer, and was made secretary general of the Faculties in 1953. He has thus had a unique experience in administering the educational and financial affairs of Cambridge, and he has made notable contributions to solving the complex problems of post-war building programmes and the academic development of the University. Dr. Taylor is in the first rank of ski-mountaineers and is also an authority on pre-Norman Conquest churches, on which he has in preparation what promises to be a definitive work. For his contributions to the study of Anglo-Saxon architecture he has recently been admitted to the fellowship of the Society of Antiquaries. To illustrate these interests he has brought a talent for photography and draughtsmanship. Despite the heavy calls of his office, he has remained readily accessible and prompt to help any member of the University staff, at whatever level, who has sought his counsel. He and Mrs. Taylor have been generous hosts, and they will leave in Cambridge many friends who will wish well to them and to Keele under Dr. Taylor's principalship.

Geography at the London School of Economics

THE constitution of the University of London is sufficiently elastic to permit the existence of many special institutions or arrangements. For the past forty years the Joint School of Geography of King's College and the London School of Economics has so flourished as to rank as the largest honours school in Britain both in numbers of staff and students. Students registered at King's College enter for degrees in the Faculties of Arts and Science, those at the London School of Economics in Arts and Economics; by tradition, though not by requirement, the professor at King's College specializes on the physical side, his colleague and joint head at the London School of Economics on the economic and human, but both are holders of University chairs of geography. As part of the post-war expansion of the social sciences, a third chair, primarily, though not entirely, a research chair, was created and occupied by Prof. L. Dudley Stamp during 1948–58, with the title of professor of social geography. Prof. Stamp was succeeded in the regular professorship and joint headship of the School by Prof. R. Ogilvie Buchanan, who was previously at University College, London (see *Nature*, 164, 475; 1949). Prof. Buchanan retires in September under the age limit after thirteen years of office, during which he has held with distinction many positions in the University—including the present chairmanship of the Academic Council.

Prof. Emrys Jones

WHEN Prof. Stamp retired through pressure of outside work in 1958, a third chair of geography was established, to which Dr. Michael J. Wise was appointed, together with a readership in social geography to which Dr. Emrys Jones was appointed. Dr. Jones now becomes the third member of the professorial triumvirate—with Prof. S. W. Wooldridge and Prof. Wise. Although the special chair or readership in social geography is now therefore in abeyance, Prof. Jones's appointment assures that the field of study, essentially the application of geographical methods of survey and analysis to present problems, will not be neglected. Trained under Prof. H. J. Fleure at Aberystwyth, he went to London after some years at the Queen's University of Belfast. His recently published book, *A Social Geography of Belfast*, is a notable contribution, breaking new ground and showing promise of new developments in the borderland between sociology and geography.

Botany at Jodhpur: Prof. C. V. Subramanian

PROF. C. V. SUBRAMANIAN has been appointed to the newly created chair in botany of the University of Rajasthan, at Jodhpur. Prior to his appointment, Prof. Subramanian had successively held the posts of lecturer (1951–53) and reader (1953–58) in botany at the University of Madras, and professor of plant pathology (1958–60) in the Indian Agricultural Research Institute, New Delhi. After graduating with a first-class honours in botany from the University of Madras in 1944, he studied soil mycology under Prof. T. S. Sadasivan in the same University, and obtained his Ph.D. in 1947 for work on the saprophytic behaviour of the *Fusarium* causing cotton wilt. In 1957 he obtained the D.Sc. degree of the same University for his work on the taxonomy of imperfect fungi. For several years past he has made an intensive study of the hyphomycetes including soil *Fusaria*, and has published many papers on the tropical forms of this group, as well as the Sphaeropsidales which had hitherto not received much attention from Indian mycologists. For some time Prof. Subramanian worked in the Botany School, Cambridge, with Dr. S. D. Garrett on soil fungi, and in the Commonwealth Mycological Institute, Kew, on hyphomycetes with Mr. E. W. Mason. Prof. Subramanian is a Fellow of the National Institute of Sciences of India and of the Indian Academy of Sciences. Although a new laboratory has yet to be constructed at Jodhpur, work has already been commenced by him on the taxonomy and biology of coprophilous and soil fungi, on the taxonomy, physiology and cytology of *Helminthosporium* species attacking cereals, and on abnormal growth in plants. B. Tiagi, appointed as reader, has a long record of active research in plant morphology and embryology. The Department will soon have a separate building together with a general herbarium of higher plants, a mycological herbarium and a collection of living cultures of fungi.

Ford Foundation Research Fellowships of the Zoological Society of London

In May 1960 the Ford Foundation made a grant of 550,000 dollars to the Zoological Society of London to endow three senior research fellowships and three junior research fellowships in animal reproduction. The Council of the Society has now appointed Dr. Peter A. Jewell, Dr. Lorna M. Kellas and Mr. D. R. S. Kirby to fellowships. Dr. Peter A. Jewell, who will hold the appointment for five years, is at present working at the Royal Veterinary College on the breeding biology of Soay sheep, which are confined to the Island of St. Kilda, and which present unique material for the investigation of a population of small ungulates. He also intends to study the reproductive performance, under laboratory conditions, of various forms of *Apodemus*. Until suitable laboratory space is available at the Society's Gardens, Regent's Park, Dr. Jewell will work in the Department of Animal Husbandry and Veterinary Hygiene, Royal Veterinary College, London. Dr. L. M. Kellas, who is appointed for three years, at present holds an appointment in the Department of Veterinary Histology, University of Glasgow Veterinary School. Dr. Kellas will make a histological and histochemical study of the intra-epithelial granular cell which occurs in the placenta of ruminants. She will also study the reproductive tracts of the giraffe, having already obtained certain material for these studies while on field expeditions to Central Africa. Mr. David R. S. Kirby has been appointed for a period of three years, as from October 1, 1960, and for the time being will continue to work in the Department of Zoology and Comparative Anatomy in the University of Oxford. He will study the effects of abnormal environments on the development of the embryo, with particular reference to the inhibitory influence of the endometrium on the spread of the cells of the trophoblast.

New Atomic Energy Authority Reactor

A new low-power reactor called *Vera* (Versatile Experimental Reactor Assembly) started operating for the first time at the Atomic Weapons Research Establishment, Aldermaston, on February 22. It is being used in reactor physics experiments to improve nuclear data and methods of calculation for fast critical assemblies. More information on these systems is required for many problems relating to the safety of storage and processing of fissile materials, and for the fast reactor development programme. The reactor includes a core region of thin-walled steel fuel tubes surrounded by a natural uranium reflector —the whole forming a cylinder 4 ft. high and 5 ft. in diameter. The fuel tubes are loaded with fissile and diluent material plates 1·7 in. square and $\frac{1}{8}$ in. thick. By appropriate loadings the composition and size of the reactor core may be varied to examine the nuclear importance of materials over a wide range of neutron energies. The reactor is designed to separate into two parts for safe loading, the two halves being brought slowly together by remote control. An accelerator associated with *Vera* enables neutron bursts to be generated for measurements of reactivity and time-dependent behaviour. The reactor is located in a large concrete cell which is sealed during operation. As the power will not exceed 100 W. special cooling is not required. This work forms part of a programme of experimental and theoretical nuclear data work at the Atomic Weapons Research Establishment and is co-ordinated with fast reactor work in progress at other establishments of the U.K. Atomic Energy Authority.

New British Base in the Antarctic

A new British Antarctic base—one of the most southerly in the chain of scientific stations maintained by the Falkland Islands Dependencies Survey—has been set up on Adelaide Island. Sir Vivian Fuchs, director of the Survey, states that the new base is on the east side of Adelaide Island, in approximately latitude 67° 40′ S. Adelaide Island is about 70 miles long and 30 miles wide with high mountains, the peaks of which reach 4,000–7,000 ft. The new base was established on February 3 and will enable the survey and geology of the Island to be completed, besides acting as a supply station from which men and stores can be flown to other bases. Two Otter aircraft have already arrived at Adelaide and are at present in the course of flying stores to Fossil Bluff, the site of a new station in lat. 71° 20′ S., long. 68° 17′ W. This will be the farthest south base in the Graham Land area, and from it exploratory journeys will be made in Alexander Island, a high mountainous region some 20,000 square miles in extent.

Afforestation in National Parks in Britain

In a written answer circulated in *Hansard* of February 14, the terms of a scheme for afforestation in the national parks in Britain is given, together with a letter sent by the National Parks Commission on January 26, 1961, to the individual park planning authorities recommending its adoption. The purpose of the scheme is to secure consultation of the park planning authorities on proposals for private afforestation of any land that has not hitherto been planted. The Timber Growers' Organization, the Country Landowners' Association, the Forestry Commission and the National Parks Commission are all anxious to secure that in the future use of land in national parks, proper regard should be given both to the needs of forestry and to the preservation and enhancement of the natural beauty of the landscape. To avoid conflict between these two interests, the parties to the agreement believe that the closest co-operation should be maintained between those concerned with afforestation and those responsible for accomplishing the purposes for which national parks have been established, and they agree accordingly that the Park Planning Authorities should be given the opportunity of commenting on all proposals for the afforestation of any land not hitherto planted. In each national park, except where special arrangements have already been made, it is proposed that the Park Planning Authority should carry out with the Forestry Commission a survey with the view of compiling maps classifying the land in the park so far as possible into: (*a*) areas where there is a strong presumption that afforestation would be acceptable; (*b*) areas where, although there is a presumption against afforestation, proposals might be acceptable; and (*c*) areas where there is a strong presumption against afforestation. These categories are devised as a general guide to policy and should be adjusted where necessary to meet particular circumstances. The surveys are intended to be discussed between the planning authorities, the National Parks Commission and the other parties to the agreement. The Forestry Commission has promised to frame its afforestation proposals in accordance with the surveys, amended as necessary after these consultations, and it is hoped that private landowners will do likewise. The arrangements will not apply outside national parks, nor to the replanting of existing woodlands. The agreement does not refer to the character or type of afforestation.

Radioactive Materials in Food and Agriculture

ALTHOUGH the references quoted in the recent report of a Food and Agriculture Organization Expert Committee, entitled *Radioactive Materials in Food and Agriculture*, and the contamination-levels available to the Committee were no more recent than 1958, and there are still wide gaps in our information, the publication represents a valuable balanced and readable general survey of the subject, and one which lays stress on basic concepts (Pp. ix + 123. Rome: Food and Agriculture Organization of the United Nations. London: H.M. Stationery Office, 1960. 7*s*. 6*d*.; 1.50 dollars). Radionuclides enter the human body, primarily via the food chain, along which a great many environmental variables can modify the contamination of the final food product. Some emphasis has been placed here on matters of soil and plant contamination, but attention is given to animal products, food processing, marine biology, human dietary aspects and overall survey and sampling problems. Although the predominant man-produced contamination of our environment with radionuclides on a world-wide scale has its origin in nuclear explosions, effluents from nuclear power-plant can be a factor of local importance. Some attention is directed to the ability of some marine forms to concentrate certain radionuclides one-hundred-fold from the sea, and to a feasible method for decontaminating milk supplies in an emergency. The Committee makes important recommendations which specify those particular fields where further research and survey work are most urgently needed. It is perhaps as well that the few errors which occur in the text so greatly alter the sense of the passage that they are easily detected; for example, on page 41, environmental carbon-14 does not amount to approximately 10–11 per cent of carbon-12.

Origin and Evolution of Coal

THE Geological Survey and Museum has published a 17-page pamphlet entitled *The Origin and Evolution of Coal* (Department of Scientific and Industrial Research. By Dr. P. J. Adams. Pp. i + 17. (London: H.M. Stationery Office, 1960.) 1*s*. 9*d*. net); this is substantially a reprint of an article that appeared in the *Fuel Economy Review* of 1955. Starting from the definition of coal as "a combustible rock which had its origin in the accumulation and partial decomposition of vegetation", it traces the history of the different vegetable ingredients that went towards the formation of coal, first through their biochemical decomposition to peat and sapropel (slimy sediment), and later through physical and chemical changes brought about by temperature and pressure during the course of the burial of peat and sapropel to greater depth. The familiar 'humic' coals, assumed to be derived from peat, together with their constituent macerals, and the sapropelic coals (cannel and boghead), are then described. Following a brief discussion of the part played in these processes by crustal movement, the lignite–anthracite series is discussed with reference to the progressive chemical changes involved. Finally, the geological record of coal formation is summarized in a useful table. Begun about 300 million years ago, this process still continues, though in small measure: for example, in the Everglades of Florida. It is thought possible that natural graphite might be derived from still earlier coals. This booklet should prove helpful to those requiring a concise picture of coal geology, for use in lecturing and teaching.

Labelling of Medicinal Preparations

A MEMORANDUM giving guidance on the procedure to be followed in devising labels and titles for compounded medicinal preparations has been issued by the Association of British Pharmaceutical Industry, the Proprietary Association of Great Britain and the Association of Public Analysts (*Labelling Procedure for Compounded Medicinal Preparations*. Pp. 6. London: Association of British Pharmaceutical Industry, 1960). Section 6 of the Food and Drugs Act, 1955, enacts certain requirements with regard to the labelling of food and drugs. When considering the provisions of the Act practitioners realize that the attitude of the public to the purchase of medicinal preparations is not necessarily identical with their approach to the purchase of food. Consequently, it may be desirable to apply to medicinal preparations labelling requirements comparable with those introduced for food by Statutory Orders and Instruments. Further, the law does not impose on medicinal preparations labelling requirements comparable with those introduced for food. The memorandum gives detailed recommendations for labelling as well as definitions of the compounds affected.

Nuclear Fusion: Journal of Plasma Physics and Thermonuclear Fusion

IT is natural, though not necessarily pleasing, that the increased interest in the physics of ionized gases should lead to the appearance of specialist journals dealing with recent developments in that subject. *Nuclear Fusion*, subtitled *Journal of Plasma Physics and Thermonuclear Fusion*, which will probably be preoccupied for some time with the former subject, is the latest addition (1, No. 1 (September 1960). Pp. 68. Published quarterly. (Vienna: International Atomic Energy Agency, 1960) Annual subscription 250 Schillings; 70*s*.; 10 dollars. Single issues 75 Schillings; 21*s*.; 3 dollars). It is a well-produced journal, with photographs and diagrams accompanying the text, although the advantage of two-column printing in a subject so mathematical as to require frequent whole-width displayed formulæ is obscure. The material in the first issue, which is of high quality, consists of the first part of a leisurely and complete survey of the oscillations of a plasma, a highly mathematical discussion of the stability of an axially symmetric plasma, a brief note on the energy distribution of thermonuclear neutrons, and two experimental papers on rapidly compressed plasmas. There is the usual impressive list of editors, and, as befits the organ of an international agency, abstracts are provided in four languages, English, French, Spanish and Russian.

Ilfracombe and District Ordnance Survey Map

THE Ordnance Survey Department has published a map at the scale of 2½ in. to the mile showing the North Devon coast from Saunton Sands to Combe Martin and extending nearly ten miles inland; Lundy Island is shown as an inset (Map of Ilfracombe and District. Sheet 856. Scale: 1 : 25,000, about 2½ inches to one mile. Chessington, Surrey: Ordnance Survey, 1961. Paper, 6*s*. 6*d*. net). Two new features have been introduced in this publication. The sheet size has been increased from the 10-km. square, at present used for Ordnance Survey maps at this scale, to 20 km. east to west by 15 km. north to south (roughly 12½ miles by 9¼ miles). In addition, to keep the price as low as possible, the cardboard cover normally used for the folded style maps has been discarded and the cover design has been printed as an integral part of the map. Covering as it does a very popular holiday and walking area, it is questionable whether the last-mentioned innovations have not, in fact, jeopardized the durability of the map, which is likely to have to stand up to some rough treatment.

Science Progress

A VALUABLE review of the giberellins by P. W. Brian, of the Akers Research Laboratories, Imperial Chemical Industries, Ltd., in the latest issue of *Science Progress* (49, No. 193; 1961) is accompanied by two other articles which should be of considerable interest to those wishing to extend their knowledge of genetics. Dr. G. H. Beale, of the Department of Animal Genetics, University of Edinburgh, describes recent work on the mechanics of cytoplasmic inheritance, while Dr. Gordon Haskell, of the Genetics Department, Scottish Agricultural Institute, reviews scientific advances in the past decade which are associated with the life-history and cyto-genetics of the genus *Rubus*. The journal also contains the usual sections describing recent developments in various branches of natural science, and many authoritative book reviews.

A Large Red-Shift

NEBULAR red-shifts up to one-fifth of the velocity of light have been reached by spectroscopic investigations. The absorption features in the spectra of even fainter and more distant galaxies are veiled by the night-sky spectrum. Emission lines remain visible for much fainter galaxies than absorption lines, and the detection of galaxies with strong emission lines would therefore permit spectroscopic determination of very large red-shifts. The investigation of radio sources offers a promising way of finding distant galaxies with emission lines; many of the strongest radio sources have been identified with such galaxies. Among the known radio sources one has now been identified with a galaxy of apparent magnitude 21, which appears to be the brightest member of a cluster of galaxies, and which has a spectrum showing a strong emission line at $\lambda 5448$ Å. The emission line is almost certainly the forbidden doublet of ionized oxygen, the laboratory wavelength of which is 3728 Å., and the large red-shift corresponds to a velocity of 0·46 times the velocity of light (R. Minkowski, *Astrophys. J.*, **132**, 909; 1960). W. A. Baum has used photo-electric photometry to determine a red-shift of 0·44 times the velocity of light for two fainter galaxies of the cluster. There is thus every reason to believe that the first galaxy is, indeed, a real member of the cluster of galaxies. These results establish the possibility of reaching red-shifts which are large enough to permit discrimination between different cosmological theories.

Scottish Field Studies Association

RECENTLY the programme for the Scottish Field Studies Association has become available and shows a welcome expansion in the scope of its courses, of which seventeen are now being offered. The majority of the botanical courses are once more centred on the Garth Field Centre. However, other courses are being organized at: the Isle of Raasay and the Isle of Great Cumbrae (marine biology); the Isle of Arran and North Ballachulish (geology); Beinn Eighe, the Isle of Arran and Strathpeffer (zoology). Two geographical field studies are being arranged from the Garth Field Centre and in the Strathpeffer region. Fees for the courses, which in each case last a week, vary from £7 to £11 3s. Further information can be obtained from the Scottish Field Studies Association, 179 West Regent Street, Glasgow, C.2.

Institute of Metals

THE spring meeting and annual general meeting of the Institute of Metals are to be held at Church House, Great Smith Street, London, S.W.1, during March 21–23. The annual general meeting will be held on the morning of March 21. On each occasion the programme is divided into two sections, *A* and *B*, which will run concurrently in the Hoare Memorial Hall and the Convocation Hall, as follows: *March* 21 (*A*) compatibility problems in gas-cooled reactors, (*B*) aluminium alloys (Prof. M. Polanyi will be giving the May Lecture, entitled "Science: Academic and Industrial", in the evening); *March* 22 (*A*) copper alloys and X-ray fluorescence analysis, (*B*) the contribution of constitutional research to general metallurgical problems; *March* 23 (*A*) extrusion, (*B*) segregation to grain boundaries. Further information can be obtained from the Secretary, Institute of Metals, 17 Belgrave Square, London, S.W.1.

International Congress on Metallic Corrosion

THE first International Congress on Metallic Corrosion is to be held at the Imperial College of Science and Technology, London, S.W.7, during April 10–15. The programme has been divided into fifteen sessions which include such topics as effects of corrosion, corrosion inhibitors, corrosion protection, high-temperature oxidation, corrosion fatigue, etc. It will also include four plenary lectures: "Chemical and Electrochemical Behaviour of Metals at Passivation Ranges", by Prof. Y. M. Kolotyrkin; "Radio-tracers as applied to the Study of Metallic Corrosion", by Prof. P. Lacombe; "The Advancing Frontiers of Corrosion Science", by Prof. H. H. Uhlig; "Factors deciding between Active Corrosion and Protective Film Formation", by Dr. U. R. Evans. Further information can be obtained from the Honorary Secretary, The First International Congress on Metallic Corrosion, 14 Belgrave Square, London, S.W.1.

Teyler Essay Competition

THE 1961 competition for the Teyler Prize, organized jointly by the Teyler Foundation and the Second Teyler Society, will take the form of an essay on modern theories of the genesis of organic matter and macromolecules originating during a phase of development of the Earth, prior to the appearance of the first living organisms. The Teyler Prize consists of a gold medal or 400 Dutch guilders. The closing date for the competition is January 1, 1963. Further information can be obtained from the directors of Teylers Stichting, Fundatiehuis, Damstraat 21, Haarlem (Netherlands).

University News:

Belfast

THE following appointments to lectureships have been announced: B. E. S. Gunning (botany); Dr. W. D. McGrath (physical chemistry); B. C. S. Wilson (archæology). Grants have been received as follows: from the Department of Scientific and Industrial Research, £695 for the purchase of an argon chromatograph, and £768 for the purchase of a gas chromatograph with flame ionization detector, both for research in the Department of Chemistry; from the Wellcome Trust, £5,500 for the purchase of an Akashi electron microscope and an ultramicrotome for use in research by the Department of Zoology.

Birmingham

AMONG the recent appointments are the following: J. W. Fortey, to be lecturer in civil engineering; D. E. N. Davies, to be Associated Television Fellow in the Department of Electrical Engineering; B. Henderson, to be William Gibbins Research Fellow in the Department of Physical Metallurgy; Dr. A. I. Rees to be Imperial Chemical Industries Fellow in Geophysics in the Department of Geology.

Keele

THE Nuffield Foundation has given £20,000 to the University College of North Staffordshire for the purpose of setting up and maintaining a special library, to be known as the Nuffield Library, appropriate for the foundation year of general studies in the College. This Library, to be housed in the new University Library building under construction, will contain multiple copies of a number of texts which are basic to the study of each of the twenty or more subjects which go to make up the foundation year course. Part of the grant is to be available to keep this Library constantly up to date.

London

DR. F. F. HEYMANN has been appointed reader in physics in the University of London, and Dr. J. Lewis reader in chemistry in the University of London, in respect of posts held by them at University College.

Sheffield

THE following appointments have recently been announced: Dr. S. C. R. Dennis, senior lecturer in applied mathematics; Dr. R. C. Hewson-Brown, lecturer in applied mathematics; Dr. D. S. Dugdale, Speedicut research fellowship in mechanical engineering; J. Beech, United Steel Companies' fellowship in metallurgy; D. H. Warrington, J. H. Andrew fellowship in metallurgy; A. Mitchell, C. H. Desch research fellowship.

Announcements

PROF. J. D. BERNAL, professor of physics in Birkbeck College, University of London, has been elected a member of the Czechoslovak Academy of Sciences, in recognition of his outstanding contribution to scientific knowledge in the field of physics.

SIR THOMAS SCRIVENOR, deputy high commissioner for Basutoland, the Bechuanaland Protectorate and Swaziland, has been appointed secretary of the Commonwealth Agricultural Bureaux.

THE third meeting of the Biological Engineering Society is to be held in Bristol on April 29. The Society will be visiting the University, in particular the Department of Anæsthetics and the Burden Neurological Institute. Further information can be obtained from Dr. A. Nightingale, Physics Laboratory, St. Thomas's Hospital, London, S.E.1.

A GENERAL meeting of the Association of Applied Biologists is to be held at the Manor House, Rothamsted Experimental Station, Harpenden, on March 10. The meeting will include a symposium on "Physiology of Field Crops". Further information can be obtained from Miss G. N. Thorne, Rothamsted Experimental Station, Harpenden, Herts.

A ONE-DAY symposium on the application of interference microscopy to problems of research is to be held by the Royal Microscopical Society on March 15 in its rooms at Tavistock House South, W.C.1. Further information can be obtained from the General Secretary, The Royal Microscopical Society, Tavistock House South, Tavistock Square, W.C.1.

THE fourth symposium in agricultural meteorology will be held in the University College, Aberystwyth, on March 8. The topic for discussion is "Soil Climate with Special Reference to the British Isles". Particulars can be obtained from Mr. James A. Taylor, Department of Geography and Anthropology, University College, Aberystwyth.

THE fourteenth Laboratory Animals Centre Congress is to be held at the University of Bristol during April 10–11. Admission to the Congress is by invitation only. Forms of application and further information can be obtained from the Director, Laboratory Animals Centre, Medical Research Council Laboratories, Woodmansterne Road, Carshalton, Surrey.

THE Third Australian Spectroscopy Conference will be held in the Chemistry School, University of Sydney, during August 22–24, under the sponsorship of the Standing Committee on Spectroscopy of the Australian Academy of Science. The Conference will cover all aspects of pure and applied spectroscopy including the newer fields such as resonance spectroscopy. Further information can be obtained from Dr. L. E. Lyons, Department of Physical Chemistry, University of Sydney.

GEOCHEMICAL LABORATORIES, LTD., 2 Elmfield Avenue, Teddington, Middlesex, announce that these Laboratories, hitherto carried on in partnership by Mr. H. B. Milner and Mr. A. H. Clarke, will be continued by Mr. Clarke under the same name. Mr. Milner will continue to be actively concerned with the Laboratories and has agreed to act as consultant and adviser.

RECENT DEVELOPMENTS IN PLANT NEMATOLOGY

THE Association of Applied Biologists held a symposium on "Recent Developments in Plant Nematology" on January 20 at the British Museum (Natural History). The symposium was well attended and appears to have been appreciated.

Dr. H. C. Gough (National Agricultural Advisory Service, Cambridge), speaking on "The Importance of Plant Parasitic Nematodes in Britain", pointed out that the root nematodes, species of *Heterodera*, are the most serious pests. *H. rostochiensis* infests at a detectable level more than 80 per cent of potato fields in Holland, Lincolnshire, and about 40 per cent in the Isle of Ely ; about 10 per cent of the total potato acreage in eastern England is infested badly enough to cause serious crop loss. In the case of glasshouse tomatoes, the pest often has to be controlled by costly steam sterilization. *H. schachtii* infests about 2 per cent of the total beet-growing area, and a sugar beet eelworm order was introduced in 1943 to reduce the spread and build-up of the pest by control of cropping. Pea root eelworm *H. göttingiana* could well become a serious pest in the rapidly expanding vining pea industry. Stem eelworm, *Ditylenchus dipsaci*, is most serious on narcissus and tulips in the bulb-growing areas. On narcissus, it is controlled to a considerable extent by regular hot-water treatment, but on tulips no similar satisfactory treatment has yet been devised. Stem eelworm in oats is fairly widespread, though most prevalent in northern Britain, but losses can be prevented by the use of good resistant varieties of oats. *Aphelenchoides ritzemabosi* on chrysanthemums, always a serious potential pest, is now controlled by parathion dipping of stools and cuttings at a very low cost.

Dr. J. B. Goodey (Rothamsted) chose as his topic "Taxonomic Relatedness", and claimed that the recognition of new species has led to progress in solving some refractory problems in nematology. He illustrated this by referring to the fragmentation of the old taxa *Heterodera schachtii* and *H. marioni* into a number of recognizable species of *Heterodera* and *Meloidogyne* respectively. In *Ditylenchus* less progress has been made, for although the stem nematodes are now split into three species, *D. dipsaci* is still recognized as containing numerous 'biological races'. Work on *Xiphinema diversicaudatum*, a virus vector, shows that the standard monograph, containing the description of this species, appears to err. The variation shown by this nematode is extensive enough to suggest two possible species if only the extremes are taken, indicating the need to treat taxonomy dynamically with the study of plenty of living material. It was suggested that the taxonomist should not regard himself or others as infallible. The adequate description of new species requires the consideration of about 150 aspects of a nematode, and while to others his work might appear intuitive and subjective, his feet are kept firmly on the earth by the necessity to explain unambiguously his conclusions to sceptical colleagues.

In discussing "The Ecology of Soil Migratory Nematodes", Dr. R. D. Winslow (Rothamsted) defined these nematodes as those root-feeding members of the Tylenchida and Dorylaimoidea in which the female does not become cystic. In the soils investigated by him at Rothamsted and elsewhere *Pratylenchus*, *Paratylenchus*, *Tylenchorhynchus*, *Rotylenchus* and *Helicotylenchus* are most common, with *Pratylenchoides*, *Criconemoides*, *Hemicycliophora*, *Trophurus*, *Longidorus*, *Xiphinema* and *Trichodorus* occurring occasionally. In arable crops at Rothamsted and Woburn (Beds.) highest numbers of total nematodes and of total Tylenchida occur in late summer or autumn. Generally at Rothamsted, and in some cases at Woburn, these numbers are well maintained during winter, falling in spring to a minimum in May or June. Other factors greatly affecting nematode numbers are vegetation, soil-type and *p*H. Cereals generally support more plant-parasitic and other nematodes than do potatoes and sugar beet. Spiral nematodes are numerous in the heavy soil at Rothamsted; very rare in the lighter Woburn soil. *Pratylenchus pratensis* is associated with low *p*H on a hay-field at Rothamsted (probably due to *p*H affecting the botanical composition of the sward), whereas the fungivorous *Aphelenchus avenae* is associated with high *p*H. In forest nurseries *Hoplolaimus uniformis*, *Trichodorus pachydermus* and *A. avenae* are associated with relatively high *p*H.

Mr. F. G. W. Jones (Rothamsted) first briefly summed up the present state of knowledge of "The Orientation and Host-finding by Soil-inhabiting Plant-parasitic Nematodes" by saying that there appears to be no evidence of nematode response to *p*H gradients, and that tests on response to temperature gradients have not been made. There is evidence of response to moisture gradients, to carbon dioxide, to certain acidic oxidizing and reducing compounds, to root exudations of unknown constitution and possibly to the products of bacterial activity in the rhizosphere. Response to redox potentials and to electric currents is also known. He then described some of his own work on the behaviour of various nematodes, *Turbatrix aceti*, *Heterodera schachtii* larvæ and *Ditylenchus dipsaci*, when exposed to electrical gradients. Nematodes respond to electrical gradients of more than 30 mV./mm., and, as many nematodes are about 1 mm. long, this represents a change of potential from head to tail. In a gradient of 100–200 mV./mm., *D. dipsaci*, which have been moving at random, tend to move more spasmodically and to swing their heads in a wide arc. Often, after this preliminary swinging movement, the head tends to face the cathode, followed by free swimming towards it. When the current is reversed, movement follows, leading to a reversal of the direction of swimming.

Mr. C. C. Doncaster (Rothamsted) showed a film of "Some Nematode Feeding Mechanisms". This illustrated the feeding of spear-bearing nematodes and those with open stomas. In the first group, *Aphelenchus avenae* thrusts the spear repeatedly against a fungal hypha followed by a rapid pumping action of the valve of the median bulb, thus ingesting the contents of the hypha ; but in *Aphelenchoides ritzemabosi*, feeding on mesophyll cells of *Stellaria media* in a water mount, the median bulb shows only gentle pulsation while the spear is inside the cell. It was suggested that feeding in *A. ritzemabosi* may be more the tapping of cell sap under pressure. In the second group, *Diplogaster* sp., *Pelodera lambdiensis* and *Rhabditis oxycerca* are saprophages. In *Diplogaster*, food particles are sucked in by the expansion of the tri-radiate lumen of the corpus (first bulb), which acts rather like a pipette. The lumen through the base of the corpus can be closed completely and acts as a valve. From the first bulb, food is transferred through the isthmus and second bulb by a wave of peristaltic-like action caused by successive contractions of the radial muscles surrounding the tri-radiate lumen of both parts. In *P. lambdiensis* and *R. oxycerca* the second bulb has three equally spaced valve plates which move backwards into a cup-like cavity. The whole process of feeding is very complex, but appears to be divisible into the following stages: (*a*) the procorpus and corpus open, drawing in food and, on closing, food collects in the forepart of the isthmus; (*b*) this food mass is carried further back to the valve by a wave of 'peristalsis'; (*c*) the cup behind the valve dilates, sucking the food through the valve flaps, which then flick back into the cup together with the whole of the anterior part of the valve; (*d*) the cup collapses, forcing the food into the œsophago-intestinal canal behind it, this canal also showing 'peristaltic' dilation and collapse.

Dr. H. R. Wallace (Rothamsted), in discussing "Plant Reaction to Parasitism by Nematodes", listed some of these reactions; he mentioned rounding of cells and loosening from one another, possibly by the action of pectic enzymes in tissues attacked by *Ditylenchus dipsaci*; the formation of giant cells in roots attacked by *Heterodera* spp. and *Meloidogyne* spp., possibly indicating the presence of growth hormones; cell hyperplasia and hypertrophy in roots attacked by *Radopholus similis*, and extensive necrosis associated with the invasion of roots by *Pratylenchus* spp. He went on to describe his work on the attack in chrysanthemum leaves by *Aphelenchoides ritzemabosi*. In susceptible varieties few cells appear to be attacked, the nematodes remain very near their point of entry, and reproduction goes on; but in resistant varieties many cells are attacked, the nematodes move far and wide and there is almost no reproduction. Resistant varieties show rapid and extensive leaf discoloration associated with the enzymic oxidation of plant polyphenols, and it is suggested that there is an absence of some nutritional factor in these leaves. Dr. Wallace ended by stressing the state of our ignorance of the inter-relationships, particularly biochemical ones, of nematode parasite and plant.

Dr. R. S. Pitcher (East Malling Research Station) spoke on "Nematode Vectors of Virus Diseases", and said that it was the pioneer work of Hewitt and Raski in California that first showed the transmission of virus by nematodes. He stressed that though this work is important in its own right, it should also stimulate study of the complex inter-relationships of nematodes and other 'soil inhabiting' pathogens and their relation to the plant and its environment. Of the 'soil-borne' viruses, those that have been transmitted by nematodes could be classified as having infectivity destroyed by air-drying of soil, and while 'tobacco rattle', which is transmitted by *Trichodorus pachydermus*, has rod-shaped particles, the others have isometric particles, for example, 'fanleaf of grape', 'peach yellow bud mosaic' and 'arabis mosaic' transmitted by *Xiphinema index*, *X. americanum* and *X diversicaudatum* respectively and 'tomato black ring' transmitted by *Longidorus elongatus*. There is a clear correlation of disease and the presence of nematodes which are all members of the Dorylaimoidea, with relatively long spears when compared with most members of the Tylenchida, none of which is known as a virus vector. The means by which virus transmission takes place is unknown and, as yet, a matter for speculation.

"Practical Problems and Recent Trends in Nematode Control" was the topic chosen by Mr. F. C Peacock (Plant Protection, Ltd., Jealott's Hill), who said that many of the earliest nematicides which still give good service are halogenated hydrocarbons. They are generally phytotoxic and relatively volatile substances. Methyl bromide and D–D are early examples and 1,2-dibromo-3-chloropropane a more recent one. A second group of nematicides are the organic phosphates: parathion has been used for some years; more recent examples are O-2,4-dichlorophenyl-, O-diethyl phosphorothioate and diethyl pyrazinyl phosphorothioate. This group of compounds is non-volatile and relatively insoluble in water, but has high nematicidal and residual value and low phytotoxicity, albeit high mammalian toxicity. Dithiocarbamates make good soil sterilants but have high phytotoxicity; their action against nematodes is said to be due to the breakdown product methyl *iso*thiocyanate. Various sulphur compounds, such as chlorophenyl methyl rhodanine, have high phytotoxicity which is useful in seed-bed preparation, but the tetrahydrothiophene dioxides and trithiophene (occurring in *Tagetes erecta*) have low phytotoxicity. Recently the use of yellow oxide of mercury incorporated in soil has shown promise. The observation that a glycoside from *Asparagus officinalis* roots inhibits nematode attack has led to an investigation of the systemic use of maleic hydrazide and other substances, applied to leaves to prevent attack on roots either by the exudation of toxic material or the inhibition of attractive diffusates, or theoretically the preferable killing of already established parasitic nematodes. Mr. Peacock finished by stressing the need for good husbandry so that nematicides are only supplementary in function, and the need for recognizing that different nematode diseases need treatment by different nematicides.

J. B. GOODEY

AREA OF RESIDENCE OF MENTAL HOSPITAL PATIENTS

ONE of the Registrar General's series of studies on medical and population subjects contains detailed statistics about the areas from which patients were admitted to mental hospitals in England and Wales during 1957. (*Studies on Medical and Population Subjects*, No. 16; "Area of Residence of Mental Hospital Patients", H.M.S.O. 15*s*. 6*d*. net.) The addresses of patients at the time of admission have been classified according to the administrative areas in which they are situated. Separate tables are given showing, for the first time, the numbers of admissions from each county borough and administrative county and from each metropolitan borough in the County of London. Figures are given separately for each sex and for certain age-groups and diagnoses.

Total admissions to mental hospitals during 1957 numbered 88,943, of which 48,266 (or 54 per cent) related to patients admitted to a mental hospital for the first time. Separate figures are given for total admissions (that is, first admissions and all re-admissions) and first admissions from each area and comparisons can be made on either basis. Most of the figures which follow are based on the total number of admissions and not on the number of persons admitted and do not therefore necessarily reflect differences in the proportion of persons in an area who were admitted to a mental hospital during the year.

Of the total number of admissions, 6,859 came from the County of London, while admissions from the counties of Middlesex, Kent, Essex, Surrey and Hertfordshire numbered 4,722, 3,674, 4,054, 3,214 and 1,571 respectively, giving a total of 24,094 for London and the surrounding counties. Among the counties outside Greater London, the highest numbers of admissions were of residents in Lancashire (2,947), and the West Riding of Yorkshire (2,395).

Although the volume only contains figures of the numbers of admissions, it is possible to relate these figures to the estimated populations of the areas at June 30, 1957, to give admission-rates per 1,000 population. The ten county boroughs with the highest number of admissions, with the corresponding admission-rates per 1,000 of the resident population, were as follows :

Birmingham	2,096 (1 9)	Sheffield	812 (1·6)
Leeds	1,023 (2·0)	Cardiff	761 (3·0)
Liverpool	1,005 (1·3)	Stoke-on-Trent	735 (2·7)
Manchester	836 (1·2)	Kingston upon Hull	702 (2·3)
Bristol	823 (1 9)	Bradford	622 (2 2)

Admission-rates for Lancashire and the West Riding of Yorkshire were 1·4 and 1·5 per 1,000 respectively.

Among individual metropolitan boroughs of London those having the highest rates of admission were Stoke Newington with 2 19 (144 admissions) per 1,000 and Stepney and Chelsea both with 2 8 per 1,000 of the population (274 and 144 admissions respectively).

The higher rates of admission are not concentrated in those counties with a greater degree of industrialization. For example, the rates for Staffordshire and Durham were 1·7 and 1·6 compared with 2·5 and 2·1 per 1,000 of the population, respectively, for Cornwall and Norfolk.

There were 1,553 admissions of patients stated to have no fixed abode, or 1·7 per cent of the total number admitted. Among these the number of re-admissions was 913 or 59 per cent, a figure well above the national percentage of 46. The admissions of patients normally resident outside England and Wales numbered 188 or 0 2 per cent of the total number of admissions.

Among the causes of admission, manic-depressive reaction contributed the largest proportion for England and Wales as a whole. Of the national total of 4,868 admissions due to character, behaviour and intelligence disorders, 440 were from the County of London and a further 322 were of people with no fixed abode. In London, 1,954 out of the 6,859 admissions resulted from schizophrenia (28 per cent) and 30 per cent were for manic-depressive reaction.

The proportions due to schizophrenia among the admissions from the ten county boroughs shown above were :

Birmingham	22 per cent	Sheffield	21 per cent
Leeds	14 ,, ,,	Cardiff	18 ,, ,,
Liverpool	31 ,, ,,	Stoke-on-Trent	22 ,, ,,
Manchester	36 ,, ,,	Kingston upon Hull	24 ,, ,,
Bristol	20 ,, ,,	Bradford	18 ,, ,,

By comparison, the proportions due to schizophrenia among the admissions from the predominantly rural counties of Cornwall and Herefordshire were 11 and 9 per cent respectively.

Of the first admissions for the whole country, 6,906 were reported as due to schizophrenia (14 per cent) compared with 13,902 admissions or 29 per cent for manic-depressive reaction.

COMMUNITY MENTAL HEALTH

With the aid of a generous grant from the Nuffield Provincial Hospitals Trust, Political and Economic Planning has recently begun a three-year study of the mental health services of Britain with particular emphasis on the subject of community care. The work is under the control of a steering group, the director of research being Dr. F. M. Martin, of the University of Edinburgh. A broadsheet, entitled "Community Mental Health Services", gives a general background to the work and shows why, and in what directions, research is necessary*.

The greater part of the research programme of Political and Economic Planning will take the form of a study of the actual operation of community mental health services in selected areas. Districts will be chosen for study primarily because they have already developed distinctive and interesting patterns of community care, such as might prove models for other areas. It is hoped that, in at least some areas, it will be possible to work in association with locally based research workers who are already interested or actively concerned in the study of mental health services. An assessment of a particular form of organization of services must take account of the statistics of patient movement, but these cannot be adequately evaluated in isolation. It will be particularly important to make some estimate of the social and personal consequences for patients and their families, of different patterns of care, and to study closely the nature of the community services provided.

In view of the wide variety of workers likely to be engaged in community care, and of the contradictory views which have been expressed on their place in the mental health services, it would be of interest to attempt some systematic analysis of the work actually performed by health visitors, psychiatric social workers, mental welfare officers, and so on. In this way it should be possible to set an analysis of professional functions against an analysis of the needs of patients and families, and to consider how effectively they can be related to one another. A comprehensive area study should also take account of the part played by voluntary organizations and of the work of the family doctor, whose potential short-term and long-term contribution to a community-oriented mental health service has yet to be satisfactorily defined.

---

* *Planning*, 26, No. 447 (12 December, 1960) · "Community Mental Health Services". Pp. 337–356. (London: Political and Economic Planning, 1960.) 2*s*. 6*d*.

In the mental deficiency field, where there is a longer tradition of community care, there seems to be fewer self-conscious experiments in progress outside the hospital service. Most local authorities appear to believe that the desirable pattern of care has been fairly well worked out, and that they know at what goals they should be aiming. There is little or nothing on the mental subnormality side comparable to the research now in progress, or being planned, for the mentally ill. There may therefore be fewer opportunities for collaborative research, but it would be desirable, in areas selected for intensive study, to examine how mental subnormality services function, and how far they meet the needs of the mentally subnormal and their families.

Another issue, deeply involved in the functioning of mental health services, is that of public attitudes towards mental disorders. The beliefs and attitudes which are, in fact, prevalent in different segments of society must inevitably influence the way in which mental health services function. They are likely to affect what is defined and recognized as 'mental illness,' to condition the response of families to illness in one of their members, and to influence both the demand for treatment and the post-hospital resettlement of former patients. There have not been many systematic studies of attitudes towards mental disorder; but it seems that the structure of such attitudes is, in fact, complex, that their psychological roots are deep, and that they have an important irrational component. It may be profitable to consider undertaking certain limited studies of attitudes and beliefs, possibly in the areas chosen for general investigation. The studies may be confined, in the first instance, to the close relatives of psychiatric patients, and to certain professional groups having special responsibilities for the care of the mentally disordered.

The scope of Political and Economic Planning's inquiry will depend on the degree of collaboration with other workers, and on the extent to which further resources may become available. There is every reason to hope that even a modest set of operational studies of the work of the mental health services may make a useful contribution to the further development of community care.

THE HYDROCHARITACEÆ IN NEW ZEALAND

ONE member of the tribe Anachriteæ of the family Hydrocharitaceæ, *Elodea canadensis*, has long been established in New Zealand and is now well known and widespread. R. Mason, of the Botany Division, Department of Scientific and Industrial Research, Christchurch, has now collated information from recent expeditions about this and other species in the family (*New Zealand J. Sci.*, 3, No. 3; September 1960).

E. canadensis has not been as aggressive or so fast-spreading in New Zealand as in Britain, in spite of its initially rapid spread in New Zealand. Cheeseman (1920), when recording it for Featherston, said, "Considering how rapidly this plant increased when first introduced into Britain, it is somewhat remarkable that its spread in New Zealand has been slow since its first introduction in 1870". In 1906, 38 years after its introduction, Cheeseman had only three listed districts, Mongonui, the Bay of Plenty, and the Canterbury Plains. In 1922 Thomson said it "is now abundant throughout New Zealand". "Judging by its distribution as known at present, if Cheeseman perhaps understated the extent of its distribution, Thomson overstated it". As New Zealand conditions are different from those in Britain or Europe in many ways, the behaviour of this plant would be expected to differ. In New Zealand *E. canadensis* would have met more vigorous competition from watercress than in Britain, for watercress had been introduced in New Zealand less than twenty years before and "it immediately spread aggressively and grew to an immense size far exceeding anything seen in Great Britain".

It is not known how abundant *Egeria densa* was in the Waikato when it was first collected there in 1946, but to-day it seems the commonest weed in the river from Rangiriri downstream as far as fresh water aquatics go—some 35 miles or so. In 1958, large beds of the weed were found wherever the river was examined; the weeds reached the surface along the river edges and formed submerged weed beds well into deeper waters. In Whangape Lake, it was found to form broad beds a short distance off-shore, apparently stretching all the way around the edge.

In Waihou River, where it was found in November, 1959, it seemed to be scattered in patches rather than in large-size, continuous beds.

In 1950, when *Lagarosiphon major* was found in New Zealand, it almost covered the bed of the Waiwhetu Stream in its lower reaches above tidal influences. According to A. P. Druce it is still abundant and is mixed with *Elodea canadensis*. Druce also recently found it in a cut-off of the Hutt River behind Barton's Bush, about 8½ miles from Woburn, the nearest previously known station.

In Lakes Rotorua, and in Hamilton Lake, growth of this weed is sufficiently great to interfere seriously with fishing, boating and swimming. At Rotorua the position has become so alarming that a special committee, including representatives of the Departments of Agriculture, Lands and Survey, Internal Affairs and the Marine Department, has been formed to tackle the problem of controlling and destroying the weed.

The weed has only recently begun to grow with such vigours, although it has been present in the Lake for a long time. It has been suggested that aerial top dressing in the district has suddenly increased the fertility of the Lake water; it is far more likely that the less-vigorous *E. canadensis* has been present for many years and that *L. major* is a much more vigorous newcomer attracting attention.

Mason also describes the establishment and means of distribution of all three species.

CHOICE OF TREE SPECIES

A PUBLICATION on forestry issued by the Food and Agriculture Organization tends to make one ask: "What has forestry to do with food and agriculture?" In the introduction to a recent Forestry Development paper entitled *Choice of Tree Species**, we are told that it is a contribution to the general *World Forest Planting Manual*, about which it gives no more information. One next asks: For whom is this work intended? Its primary object is stated to be to summarize what is known about the factors which should guide the practising forester in reaching a decision about the choice of species. The second object is said to be to stimulate foresters to amplify and correct the often inadequate information presented in this book. With regard to the first object it must be said right away that the summary is extremely faulty in respect both of the completeness of the information and of the manner of its treatment. With regard to the second object, this seems to imply that the aim of a publication is not to furnish information but to ask for information.

This type of publication is a feature of the present day. The setting up and staffing—at considerable expense—of global organizations from above downwards instead of building them on well-founded services from below upwards lead to attempts being made to produce text-books intended to be of universal use. The time has not yet come when natural agencies will have reduced the face of the globe to one monotonous landscape. Perhaps in no other field is there a greater variety of working conditions than in forestry. As the author, or authors, say (p. 69), "It is, of course, quite impossible to suggest general rules on the selection of species and sites for production which would be applicable in all circumstances". Nevertheless, they have attempted the impossible. Then again (p. 170) it is admitted that "The information available from different parts of the globe is so variable that uniform presentation is not possible". Uniform presentation has not been achieved. There are very serious gaps in the sources consulted, especially in respect of European countries; some works in English on the subject have been overlooked; recent developments in the study of the major site factors are unrecorded; conclusions are accepted and illustrations reproduced from examples of plantations too young to have proved their suitability; there is a lack of discrimination in assessing the relative importance of the many publications quoted; there is a very evident bias in the selection of material and too narrow an outlook on this extremely difficult problem.

The fact is that it would be unwise to recommend to any practising forester that he should purchase and consult this book—or any book of such a global type; it would be far better that he should be advised to consult the literature available in respect of the narrower field with which he is concerned, or of areas like it. To help him in this, all that is required is information on the literature referring to his conditions, to furnish which is the task—admirably performed—of the Commonwealth Forestry Bureau, Oxford.

The age of the superman has not yet arrived. No one is qualified to undertake satisfactorily such a tremendous task as that attempted in this case. The eyes of a fool are in the ends of the Earth. It was unwise of the Food and Agriculture Organization to sponsor this book, and one can only offer sympathy to those who were enticed into wading through a vast amount of heterogeneous literature to produce it. It is understood that the Organization is assisting with forestry publications dealing with certain restricted geographical regions. This is more rational and should prove more useful.

If one is eclectic and chooses the parts of special interest to oneself, there is something of value to be had from the book. Part 3, for example, consists of monographs on four widely differing species—Norway spruce, Monterey pine, teak and blue gum, which demonstrate effectively the wide differences among tree species which render difficult the writing of a global text-book. M. L. ANDERSON

ENERGY-LINKED CYTOCHROME OXIDATION IN MITOCHONDRIA

By PROF. BRITTON CHANCE

Johnson Research Foundation, University of Pennsylvania, Philadelphia, Pennsylvania

THE study of succinate-linked reduction of pyridine nucleotide in mitochondria was begun some time ago[1]. More recent work demonstrates that reduction of diphosphopyridine nucleotide in mitochondria is an energy-linked reaction having a definite requirement for internal high-energy intermediates[2] or for adenosine triphosphate itself[3]. Although previous attempts to demonstrate a requirement for adenosine triphosphate failed[2], these recent experiments demonstrate the possibility of driving electron transfer reactions in the respiratory chain in reverse by means of high-energy intermediates, and it has been of interest to determine whether or not cytochrome reduction induced by substrate could be reversed by adenosine triphosphate, a possibility that is particularly attractive in connexion with theories of active transport[4,5] and photosynthesis as well. (Lundegårdh[6] has reported an effect of adenosine triphosphate (and fumarate) on the interaction of cytochromes *b* and *dh* in anaerobic wheat roots, cytochrome *dh* being "turned over into a state of strong reduction under the influence of adenosine triphosphate (and fumarate) simultaneously with cytochrome *b* remaining more oxidized". The interpretation of this interesting result is rendered ambiguous by the fact that the existence of cytochrome *dh* in wheat roots and other plant or animal tissues has not been confirmed by other workers[7] nor by us using liquid-nitrogen spectroscopy of wheat root mitochondria (B. Chance and W. D. Bonner, jun., unpublished observations).)

The present article reports that addition of adenosine triphosphate causes the oxidation of cytochromes of mitochondria in the presence of dithionite or terminal respiratory inhibitors such as cyanide or sulphide. Stoichiometric and kinetic results indicate that this is a fairly efficient reaction; inhibitor studies suggest more than one site of interaction of adenosine triphosphate with the respiratory chain. The relationship of these results to the responses of cytochromes to adenosine diphosphate[8] and to the adenosine triphosphatase activities of mitochondria are discussed. It is apparent that the oxidation-reduction states of the cytochrome, flavoprotein and the pyridine nucleotide components of the respiratory chain are as well controlled by the adenosine triphosphate and adenosine diphosphate + inorganic phosphate-levels as by reductant and oxidant.

Preparations. Pigeon heart mitochondria were prepared by a procedure developed in this laboratory (Chance, B., and Hagihara, B., in *Proceedings of the Fifth International Symposium of Biochemistry*, in preparation) involving the use of *B. subtilis* proteinase. With succinate as substrate such mitochondria have respiratory control ratios >3 (usually 4–5) and P/O values of 1·8 with respiratory activities corresponding to a turnover number of cytochrome *c* of 6 sec.$^{-1}$ at 26°. Freshly prepared rat liver mitochondria[9] and 'digitonin particles'[10] were also used. (Thanks are due to Mr. K. Kaminker and Miss H. Diefenbach for pigeon-heart preparations and to Dr. U. Fugmann for 'digitonin' preparations.) The reaction medium was free of phosphate and magnesium and consisted of 0·27 *M* mannitol, 0·03 *M* sucrose and 0·01 *M* *tris* *p*H = 7·3. The temperature of the experiments was 26°. The cytochrome *c* concentration under the conditions of the experiment ranged from 1 to 2 μ*M*.

The double-beam spectrophotometer[11] set at appropriate pairs of wave-lengths for cytochrome components was used simultaneously with a recording fluorometer for measuring pyridine nucleotide reduction. The latter employed 365 mμ for excitation and 450 mμ for recording[12], these wave-lengths being obtained by appropriate filters.

The split-beam spectrophotometer was used at room and liquid-nitrogen temperatures to identify cytochromes affected by the addition of adenosine triphosphate. The optical path-length was 1 mm. at low temperatures. The 'trapped steady state' method[13] was used.

Cytochrome Oxidation in the Presence of Sodium Dithionite

Although cytochrome oxidation is observed on addition of adenosine triphosphate in the presence of terminal respiratory inhibitors, there is the remote possibility in such experiments that adenosine triphosphate might somehow have interfered with the action of the inhibitor and have induced a cytochrome oxidation that was linked with oxygen and not with adenosine triphosphate. In experiments with dithionite, controls were carried out to indicate that an excess of dithionite was added so that the subsequent addition of adenosine triphosphate to the solution did not stir in sufficient oxygen to exhaust the added dithionite. This was done by titrating the dithionite solution with oxygen by means of the platinum microelectrode.

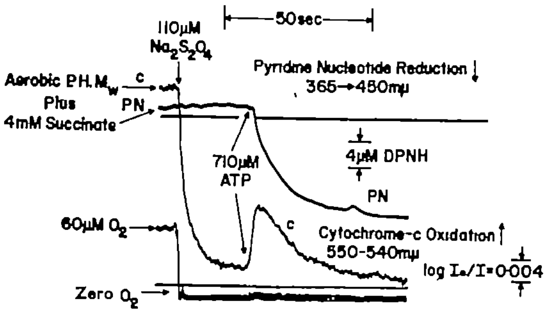

Fig. 1. Oxidation of cytochrome *c* and reduction of pyridine nucleotide caused by the addition of adenosine triphosphate to anaerobic pigeon heart mitochondria treated with dithionite, suspended in mannitol–sucrose–*tris* medium (1·9 mgm. protein/ml.). Concentrations of reactants added and the absorbancy and the concentration scales are indicated on diagram (Exp. 193*b*).

An experiment typical of this work is indicated in Fig. 1. Aerobic pigeon-heart mitochondria (essentially free of endogenous substrate) are treated with 4 m*M* succinate and cytochrome *c* is recorded spectrophotometrically, an upward deflexion of the trace corresponding to an oxidation. Pyridine nucleotide reduction is measured fluorometrically; a downward deflexion of the trace corresponding to increased fluorescence and increased reduction of pyridine nucleotide. The initial oxygen concentration of the suspension was diminished by bubbling nitrogen through the reaction medium, so that a value of 60 instead of 240 μ*M* is obtained. The dithionite solution calibrated as described above is added to a final concentration of 110 μ*M* in oxygen equivalents and causes an abrupt decrease of the oxygen concentration to zero, as indicated by the fall of the platinum electrode trace. At this time there is a rapid reduction of cytochrome *c*. There is no reduction of diphosphopyridine nucleotide, verifying that these mitochondria are free of substrate capable of directly activating reduction of this substance. As soon as the anaerobic steady state is obtained, an excess of adenosine triphosphate is added (710 μ*M*), and there is an abrupt oxidation of cytochrome *c* and a reduction of pyridine nucleotide, the rates being respectively 0·42 μ*M* iron/sec. and 1·2 μ*M* reduced diphosphopyridine nucleotide/sec. The oxidation of cytochrome *c* is transitory and its reduction soon follows, the half-time for the cycle of oxidation and reduction of cytochrome *c* being about 15 sec. The reduction of pyridine nucleotide proceeds exponentially to completion, and no re-oxidation of this component is observed. This experiment indicates that the addition of adenosine triphosphate to anaerobic mitochondria causes an abrupt cyclic oxidation of cytochrome *c* and a simultaneous reduction of diphosphopyridine nucleotide.

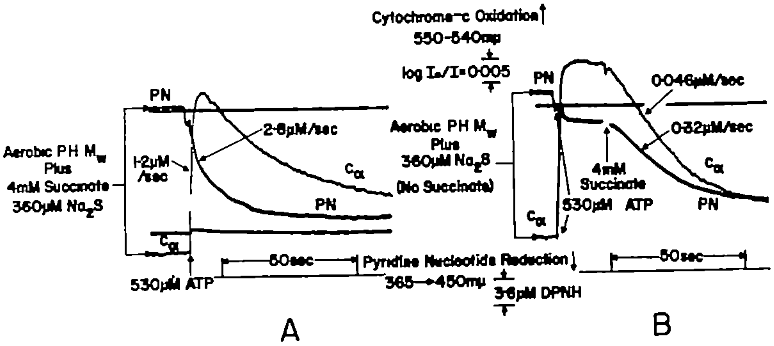

Fig. 2. Oxidation of cytochrome *c* and reduction of pyridine nucleotide in pigeon heart mitochondria inhibited with 360 *μM* sulphide. Left, in the presence of succinate and, right, in the absence of succinate. Concentrations, absorbancy calibrations and time scales are included in the figure. Mannitol–sucrose–*tris* medium, 1·1 mgm. protein/ml. Temperature, 26° (Exp. 185*b*-3)

Cytochrome Oxidation in the Presence of Terminal Respiration Inhibitors

Results similar to those of Fig. 1 have been obtained in the presence of excess cyanide or sulphide. An example of the latter is illustrated in Fig. 2*A*. In this case the mitochondria are pretreated with 4 m*M* succinate and 360 *μM* sodium sulphide. This causes complete reduction of cytochrome *c* but negligible reduction of pyridine nucleotide. On the addition of 530 *μM* adenosine triphosphate, there is an abrupt oxidation of cytochrome *c* at a rate of 1·2 *μM* iron/sec. and a corresponding reduction of diphosphopyridine nucleotide at a rate of 2·8 *μM*/sec. The maximal rate of oxygen utilization in the absence of sulphide and in the presence of phosphate + adenosine diphosphate (state 3) is 4·8 *μM*/sec. in 2-equivalent units. Thus the rate of electron transfer elicited by addition of adenosine triphosphate is high. Similar results are obtained with rat liver and brain mitochondria and with 'digitonin particles'.

As in the case of the mitochondria treated with dithionite, the cytochrome oxidation is cyclic, although longer-lived. Further additions of adenosine triphosphate cause smaller cyclic responses of the cytochromes.

Substrate Requirements for Pyridine Nucleotide Reduction and Cytochrome Oxidation

In Fig. 2*B* the experiment shown in Fig. 2*A* is repeated without succinate. There is a slow reduction of cytochrome *c* on addition of sulphide due to traces of endogenous substrate. Here the addition of adenosine triphosphate causes an abrupt oxidation of cytochrome *c* to a higher level than was obtained in the presence of succinate. Pyridine nucleotide shows only a small reduction compared with that obtained in material treated with succinate; only 20 per cent is reduced. Addition of succinate to the material treated with adenosine triphosphate allows reduction of pyridine nucleotide to proceed to the same extent that was observed in Fig. 2*A*. At the same time, cytochrome *c* reduction proceeds, but at a slower rate than the rate of pyridine nucleotide reduction. This record confirms the previous results, suggesting a specific requirement for succinate in energy-linked reduction of diphosphopyridine nucleotide[8].

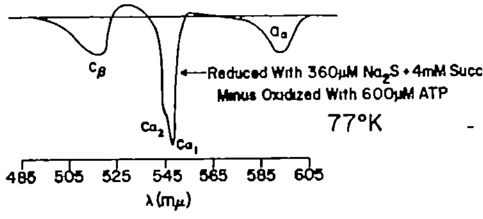

Fig. 3. Low-temperature 'trapped steady state' of oxidation of cytochromes *c* and *a*. Pigeon heart mitochondria treated as indicated in the figure, 1·2 mgm. protein/ml. Optical path 1 mm. (Exp. 185*b*–6)

Effect upon Other Cytochromes

To determine that a cytochrome oxidation has definitely occurred and to identify other cytochromes affected by addition of adenosine triphosphate, the 'trapped steady state' method of low-temperature spectroscopic observations has been employed in which the material in both cuvettes of the split-beam recording spectrophotometer is pre-treated with 360 *μM* sodium sulphide and 4 m*M* succinate. Just prior to freezing, 600 *μM* adenosine triphosphate is added to one of the cuvettes, and the spectrum representing the difference in absorbancy between the two is plotted in Fig. 3. In the interval (about 15 sec.) between addition of adenosine triphosphate and freezing, absorption peaks corresponding to cytochromes *c* and *a* have disappeared, the α_1 and α_2 peaks of the former being clearly identified. No indication of cytochromes c_1 or *b* is given in this record, and it may be presumed that directly on addition of adenosine triphosphate their oxidation states have not been measurably altered.

Time-Course of Cytochrome Change

To determine the time-sequence of the oxidation and reduction of cytochromes *c* and *a*, and to determ-

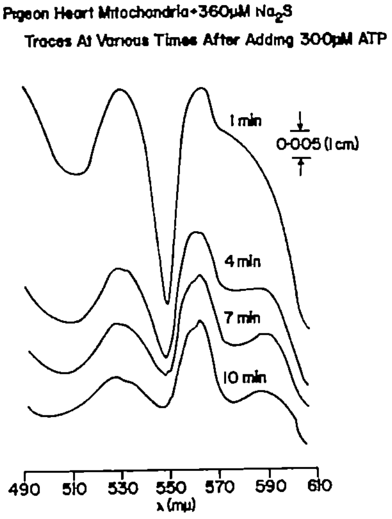

Fig. 4. Room temperature difference spectra showing the time course of the changes in oxidation- and reduction-levels of cytochromes *a*, *c* and *b*. Experimental conditions similar to those of Fig 2*B*, 1 cm. optical path (Exp. 185*c*–3)

ine whether or not any slow effects on cytochrome *b* can be observed, we have recorded (Fig. 4) in the split-beam spectrophotometer room temperature difference spectra at three-minute intervals after adding 300 μM adenosine triphosphate to mitochondria treated with 360 μM sodium sulphide (succinate being omitted, cf. Fig. 2*B*). In accordance with the results of Fig. 3, the record shows clearly the oxidation of cytochromes *c* and *a* as indicated by the disappearance of absorption peaks at 550 mμ and at 605 mμ. Since this record was traced at about 1 min. after adding adenosine triphosphate, there already appears a distinctive peak at approximately 560 mμ. After a 4-min. wait, it is observed that the oxidation of cytochrome *c* is considerably smaller, as is that of cytochrome *a*. In fact, at the end of the fourth recording, the oxidation of cytochromes *c* and *a* has subsided almost completely. The spectroscopic effect in the region of cytochrome *b* has developed and a distinct peak indicating reduction of cytochrome *b* has appeared. This peak is broad and suggests the oxidation of more than one component.

Stoichiometry of Adenosine Triphosphate-Cytochrome Reaction

In view of the considerable interest in adenosine triphosphate-driven production of electron transfer for the purposes of active transport, the stoichiometry between adenosine triphosphate and cytochrome oxidation is relevant. Fig. 5*A* illustrates the titration of cytochrome *c* oxidation with adenosine triphosphate in the absence of succinate, and it is seen that a plateau is reached with less than 10 μM adenosine triphosphate. The titration curve is sigmoid, as if some other substances were being titrated prior to cytochrome *c*, or as if a certain redox potential were required. However, a stoichiometric relationship for adenosine triphosphate and cytochrome *c* is taken from the steepest part of the curve, which corresponds to 3 molecules of adenosine triphosphate per cytochrome *c*. Since cytochrome *c* is only one of four components observed to be oxidized simultaneously, the adenosine triphosphate/electron value is approximately 1. This value corresponds fairly well with the value of adenosine triphosphate/reduced diphosphopyridine nucleotide of 1·8–2·7 for reduction of diphosphopyridine nucleotide in mitochondria treated with succinate[3]. If the total adenosine triphosphate added is divided by the total electron equivalents found in cytochromes *c*, *a* and a_3 and flavoprotein, then the ratio is larger ; 5·6 μM adenosine triphosphate gave a total of only 1 5 one-electron equivalents oxidized, presumably due to the sigmoid nature of the titration (Fig. 5*A*).

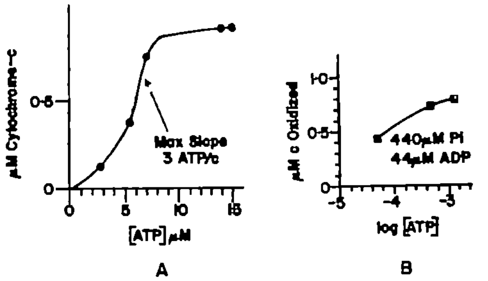

Fig. 5. Titrations of cytochrome *c* of mitochondria treated with sulphide (no succinate added) under conditions to determine an adenosine triphosphate/cytochrome 'stoichiometry' (part *A*) and an 'equilibrium' (part *B*). In the latter case phosphate and adenosine diphosphate are present. The total cytochrome concentration ($c + c_1$) was 1 2 μM in part *A*, 1·8 μM in part *B*; 360 μM sodium sulphide, 26°, mannitol–sucrose–*tris*-medium, pH = 7·4 (Exps. 198*b*, 203)

Nucleotide Specificity of the Reaction

In order to determine whether there is absolute specificity for adenosine triphosphate, we have tested the effect of various nucleotides on pigeon heart mitochondria that have been treated with succinate and sulphide as in the previous experiments. The addition of the 5′-triphosphates of ribosyl guanine, uracil, hypoxanthine and cystosine (72 μM) gives no response (less than 1 per cent), whereas adenosine triphosphate causes changes observed in Fig. 2*A*. This result is in accordance with the specificity of oxidative phosphorylation for adenosine diphosphate[14], but differs from the specificity of adenosine triphosphatase stimulated by dinitrophenol and magnesium[15].

Effects of Adenosine Diphosphate, Inorganic Phosphate and Magnesium, etc.

Experiments similar to those of Fig. 2*A* show that both adenosine diphosphate and phosphate inhibit the rate and extent of the reaction, adenosine diphosphate being considerably more effective than phosphate—an expression of their relative affinities in oxidative phosphorylation. A combination of adenosine diphosphate and phosphate is much more inhibitory, as would be expected from equation 1 (see later). It is possible to titrate cytochrome *c* with adenosine triphosphate in the presence of adenosine diphosphate and inorganic phosphate under the conditions of Fig. 2*B* (no substrate added) and an experiment on this point is given in Fig. 5*B*. It is seen that 50 per cent oxidation of cytochrome *c* can be obtained with a ratio [ADP] [Pi]/[ATP] of roughly 100, suggesting that in the absence of added substrate, oxidation of cytochrome *c* is not difficult to 'drive'. Magnesium is inhibitory and 0·7 mM magnesium largely blocks the effects of 32 μM adenosine triphosphate under conditions similar to those of Fig. 2*B*, presumably by activation of an adenosine triphosphatase that competes with the cytochrome reaction.

Dinitrophenol (4·5 μM) inhibits cytochrome-c oxidation by 50 per cent. Oligomycin (1 gm./ml.) inhibits completely. Thus the energy transfer pathway by which ATP activates reversed electron transfer is identical to that by which ADP is phosphorylated to ATP.

Effect of Ageing

Ageing of the mitochondria to the extent that respiratory control is impaired causes a considerable inhibition of the rate and extent of pyridine nucleotide reduction and of cytochrome oxidation. The cycle of oxidation and reduction of cytochrome *c* caused by the addition of adenosine triphosphate is considerably shorter, suggesting that the latter is expended not only in an energy-conserving reaction of diphosphopyridine nucleotide reduction and cytochrome oxidation, but also in the dissipative reaction involving hydrolysis of adenosine triphosphate.

Correlation with Adenosine Triphosphatase Activity

Simultaneous measurements of breakdown of adenosine triphosphate upon its addition to mitochondria treated with succinate and sulphide have been made by pH measurement[16] (unpublished work in collaboration with Drs. Saris and Ito) in order to determine the time relationships of adenosine triphosphate breakdown and the cytochrome and pyridine nucleotide kinetics. It has been found that the breakdown of adenosine triphosphate under these conditions begins at the same time as the oxidation of cytochrome and the reduction of pyridine nucleotide. It is further observed that the molar rate of breakdown of adenosine triphosphate somewhat exceeds the maximal rate of reduction of pyridine nucleotide. The rates of breakdown of adenosine triphosphate under these conditions have been compared with those observed in the dinitrophenol-activated breakdown of adenosine triphosphate and are found to be one-half to one-third the maximal rate observed. These results do not identify the pathway of breakdown of adenosine triphosphate in adenosine triphosphatase activity with the pathway of adenosine triphosphate utilization in cytochrome oxidation at the present time.

Effects of Inhibitors of Electron Transfer

Since adenosine triphosphate can interact with pairs of respiratory enzymes and does not require electron transfer through the whole chain, the effects of inhibitors on reversed electron transfer differ from those on oxidative phosphorylation obtained by electron transfer through the complete chain. Amytal, quinoline-N-oxide, and antimycin *A* slow the responses of the carriers to adenosine triphosphate, but do not eliminate slow cyclic responses of cytochromes *a* and *c*. Flavoprotein and reduced diphosphopyridine nucleotide respond to the initial addition of adenosine triphosphate (see Fig. 6), but after several further additions of the latter, the response of these components becomes negligible, pyridine nucleotide being completely reduced. In the system blocked with quinoline-N-oxide or antimycin *A*, the rate of cytochrome oxidation is so slow that electron transfer through the inhibited site to an electron acceptor such as ubiquinone is a possibility.

The oxidation of flavoprotein and the reduction of pyridine nucleotide in the system blocked with quinoline-N-oxide would appear to indicate an interaction site for adenosine triphosphate between flavoprotein and pyridine nucleotide.

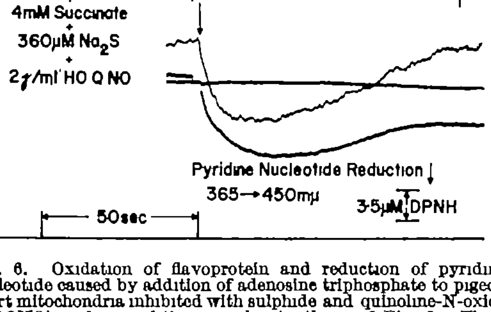

Fig. 6. Oxidation of flavoprotein and reduction of pyridine nucleotide caused by addition of adenosine triphosphate to pigeon heart mitochondria inhibited with sulphide and quinoline-N-oxide (HOQNO) under conditions similar to those of Fig. 2. Time, absorbancy, and concentration scales indicated on figure, 1·2 mgm. protein/ml. (Exp. 178)

Discussion : Relation to Active Transport and Photosynthesis

The results presented here indicate that specific oxidation-reduction reactions are induced by the addition of adenosine triphosphate to mitochondria devoid of oxidase activity due to removal of oxygen by sodium dithionite or due to respiratory inhibition by sodium sulphide. This reaction constitutes a genuine conversion from adenosine triphosphate to electron transfer, a process that has been sought for a number of years. However, it was apparent that the energy-linked reduction of diphosphopyridine nucleotide[2,3] would be accompanied by an energy-linked oxidation, provided suitable experimental conditions were found. The appropriate conditions are simple ; electron transfer proceeds rapidly in the reverse direction in mitochondria that are relatively free of magnesium, adenosine diphosphate and inorganic phosphate. This discovery may be of considerable importance to our understanding of the function of the respiratory chain, and to our consideration of new ways in which metabolic processes could be affected by the transfer of the energy of adenosine triphosphate to oxidation-reduction equivalents.

It is useful to consider, on the basis of these results, the appropriate conditions for reversed electron transfer in the living cell. In intact mitochondria in anaerobiosis, a high 'phosphate potential' (see below), generated by glycolytic activity, could cause appreciable reduction of mitochondrial diphosphopyridine nucleotide and oxidation of either succinate or of cytochrome as indicated by Fig. 5*B*. A 'phosphate potential' of a few thousand calories produces considerable oxidation of cytochrome in substrate-free mitochondria (see below). For portions of the electron transfer system, such as those postulated for active transfer[4], anaerobiosis would not be required, only an appropriate 'phosphate potential'. It is apparent that the stoichiometry of the conversion from adenosine triphosphate to electrons is not yet sufficiently favourable to merit serious consideration of the mitochondrial process as an explanation for the very high efficiency observed in gastric secretion under certain conditions[6], although the principle of conversion of the energy of adenosine triphosphate to electron transfer is proved. However, in mitochondria we would not expect a ratio of adenosine triphosphate/electron exceeding that of the phosphorylation efficiency. Our stoichiometric data ($\sim$ 1 ATP/Fe) may give a low value because a portion of the adenosine triphosphate may be (1) used to affect other carriers that are oxidized and (2) split directly without its utilization in cytochrome reactions (see later).

The response of cytochromes of photosynthetic bacteria to illumination is characteristically an oxidation of cytochrome[17,18], and in some circumstances a reduction of pyridine nucleotide[19,20]. Up to this point, it has been considered that such responses are direct consequences of the effect of the photochemically produced oxidant and reductant on a series of electron-transfer carriers. The results given here make it necessary to distinguish by further experimentation between the present hypothesis and the possibility that high-energy intermediates, produced in light-induced energy-conservation reaction, could indirectly influence a chain of electron-transfer carriers in the manner illustrated by these experimental results (cf. Fig. 2). One way of distinguishing in favour of a direct effect is by observation of cytochrome oxidation at liquid-nitrogen temperatures[22].

The phenomenon of 'water splitting' by cytochrome a_3 oxidized by adenosine triphosphate would not be unexpected in further investigations; so far we have observed that a considerable disappearance of absorption at 445 mμ occurs on addition of adenosine triphosphate to the dithionite-treated material, and is followed by a reappearance of this absorption band. It is possible that the reduction of cytochrome oxidized by adenosine triphosphate could be attributed in part to a 'water-splitting' reaction, as well as to the exhaustion of added adenosine triphosphate.

Oxidations in the Presence of Dithionite

It is remarkable that cytochrome oxidation induced by adenosine triphosphate can be observed in mitochondria in spite of the reducing power of sodium dithionite. Two explanations may be considered: (1) that adenosine triphosphate can oxidize cytochromes against the negative potential of dithionite; or (2) that dithionite does not penetrate the mitochondrial membrane (assuming that none of the cytochromes is accessible on the outside membrane of the mitochondria). In the case of the second alternative, it might be expected that no responses to adenosine triphosphate would be observed at longer times following the addition of dithionite. We have been able to observe the response to adenosine triphosphate after incubation of the mitochondria with dithionite for one and a half minutes. The lack of dithionite sensitivity recalls experiments on the light-induced oxidation of cytochromes of *R. rubrum* in the presence of a considerable excess of dithionite[23]. At the present time, we are inclined to favour explanation 2 in both cases, namely, that dithionite is acting exclusively as an oxygen absorber and not as a specific reductant of cytochromes.

Nature of the Electron Acceptor

While it is clear from Figs. 1, 2 and 3 that cytochromes are oxidized, it is important to consider the electron acceptor for this oxidation reaction. (Obviously either electrons or hydrogen atoms could be transferred.) In Fig. 2*A* the rates of cytochrome oxidation and pyridine nucleotide reduction indicate that diphosphopyridine nucleotide may be accepting about half its electrons from cytochrome oxidation, and that the remainder arise (1) from succinate oxidation or (2) from entry of adenosine triphosphate at another point in the respiratory chain to oxidize flavoprotein and ubiquinone. It is possible that both reactions occur. It is of special interest to note that in the absence of added succinate, only 30 per cent of the pyridine nucleotide is reduced, and in this case the electrons are presumably all from oxidations induced by adenosine triphosphate of other carriers. The fact that only a part of the pyridine nucleotide can be reduced by electrons transferred from adenosine triphosphate-induced carrier oxidation or from treatment of the mitochondria with a diphosphopyridine nucleotide-linked substrate[3] underlines the specific role of succinate in the reduction of the majority of mitochondrial diphosphopyridine nucleotide and supports the ideas of chemical or compartmentation differences of mitochondrial pyridine nucleotide[3].

In the absence of succinate, pyridine nucleotide can still act as an electron acceptor, although some other substance may be involved. Comparing the total of oxidized cytochromes and flavoprotein with the extent of reduction of pyridine nucleotide, more oxidized than reduced substances are found on a mole basis (1·5 : 1). However, the assay procedures should be refined, particularly that for ubiquinone, since absorption of adenosine triphosphate interferes with its assay by the spectrophotometric method[24].

The reaction kinetics of cytochromes *c* and *a* are of interest in contrast with those of pyridine nucleotide; the former resembles those of an enzyme substrate intermediate, the latter that of a product of an overall reaction. As indicated above, the difference in these kinetics is probably due to the fact that succinate supplies electrons for the reduction of a portion of diphosphopyridine nucleotide.

Speed of the Reaction

The speed of cytochrome oxidation caused by addition of adenosine triphosphate is fairly high, as illustrated by Figs. 1 and 2, but it is nevertheless only about 10 per cent of the rate of oxygen utilization obtainable in the phosphorylation of adenosine diphosphate (state 3) in pigeon-heart mitochondria. It can then be understood why the accumulation of adenosine triphosphate does not slow down respiration in oxidative phosphorylation, or at least change the state of the carriers[1,25]. In addition, phosphate + adenosine diphosphate inhibit the reverse reaction[26]:

$$\mathrm{ADP} + \mathrm{P}_i + X \rightleftharpoons \mathrm{ATP} + X \qquad (1)$$

Similarly, oxygen itself, which produces a high degree of oxidation of the carriers, inhibits the reverse reaction.

Thermodynamic Aspects

While the records of Figs. 1 and 2 show clearly that the system is not in equilibrium because of breakdown of adenosine triphosphate, it is of great interest to learn something of the [ADP] [P$_i$]/[ATP] values that are involved in the cytochrome oxidation. In Fig. 5*B* a preliminary value of 10^2 for half-oxidation of cytochrome *c* is obtained. If succinate is added, the value is greatly decreased, as would be expected from the increased reducing power. While conversion of these values to calories may not be meaningful, cytochrome *c* is half-oxidized in the absence of succinate at an [ADP][P$_i$]/[ATP] value corresponding to 3 kcal.

That some oxidation of cytochrome and some reduction of diphosphopyridine nucleotide can be observed under these conditions requires an explanation. While it is not the purpose here to present a comprehensive theory, it is suggested that a possible explanation for the oxidations and reductions over such a wide range of redox potentials with such large [ADP] [P$_i$]/ATP values is due to a reversal of electron transfer accompanied by an accumulation of the inhibited high-energy forms of the respiratory carriers. The latter reaction apparently proceeds to such an extent that the interaction of the components of the chain as a whole is sufficiently slow to enable the rapid interaction with adenosine triphosphate to control the redox-level of various couples in the chain. Thus the present work emphasizes the formation of inhibitory compounds on addition of adenosine triphosphate, whereas previous work emphasized the reversal of inhibition on adding adenosine diphosphate and inorganic phosphate[15].

Relation to Adenosine Triphosphatase Activity

In considering a difference between the 'conservative' breakdown of adenosine triphosphate in a reaction yielding oxidation of cytochrome, and reduction of pyridine nucleotide and a 'dissipative' breakdown of adenosine triphosphate without such conservation of energy, it is useful to consider the sequence of equations:

$$\mathrm{ATP} + X \rightleftharpoons \mathrm{ADP} + X \sim \mathrm{P} \qquad (2)$$

$$X \sim \mathrm{P} + \mathrm{I} \rightleftharpoons X \sim \mathrm{I} + \mathrm{P}_i \qquad (3)$$

$$X \sim \mathrm{I} \overset{\mathrm{DNP}}{\rightleftharpoons} X + \mathrm{I} \qquad (4)$$

Reaction 4 would correspond to 'dissipative' reaction and reaction 5 to a 'conservative' reaction:

$$X \sim \mathrm{I} + rfp + \mathrm{DPN} \rightleftharpoons \mathrm{DPNH} + fp + X + \mathrm{I} + \mathrm{H}^+ \qquad (5)$$

Cross-over Points for Adenosine Triphosphate Interaction

Reaction 5 is based on the evidence of Fig. 6, namely, that flavin oxidation and pyridine nucleotide reduction occur in the system inhibited by quinoline-N-oxide; both the flavin and the pyridine nucleotide are associated with the side pathway involved in succinate-linked reduction of pyridine nucleotide[2,25,27] There appears to be a cross-over point for the oxidation-reduction reaction induced by adenosine triphosphate, which corresponds to a cross-over point between reduced diphosphopyridine nucleotide and flavin observed in response to adenosine diphosphate under appropriate conditions[28]. We have not yet discovered suitable conditions for demonstrating clearly other cross-over points which would indicate further similarities in the interaction sites for adenosine tri- and di-phosphate, one being expected between cytochromes c and a, and another between cytochromes c_1 and b (refs. 13, 28). It is apparent from these results that the behaviour of cytochrome b differs sharply from that of cytochrome c, the latter being rapidly oxidized and cytochrome b being slowly reduced. Thus a second cross-over point exists in this region of the chain. It remains to determine the role of cytochrome c_1 in this transition by work on 'trapped' steady states at liquid-nitrogen temperatures.

So far, no indication has been obtained of a cross-over point between cytochrome c and a, although this, of course, does not signify that the interaction does not occur here[26]. Thus there is no evidence available at the present time which indicates that the sites at which adenosine triphosphate interacts with the respiratory carriers to give 'reversed' electron transfer differ from the sites at which adenosine diphosphate is phosphorylated to adenosine triphosphate by means of 'forward' electron transfer.

This investigation was supported in part by the National Science Foundation.

Note added in proof. In work "On the Reversibility of Oxidative Phosphorylation", an oxidation of cytochrome c and reduction of flavoprotein induced by adenosine triphosphate have been observed in aerobic suspensions of rat skeletal muscle mitochondria[29]. More recently, it has been suggested that the aerobic results indicate an inhibition of electron transfer and not its reversal[30].

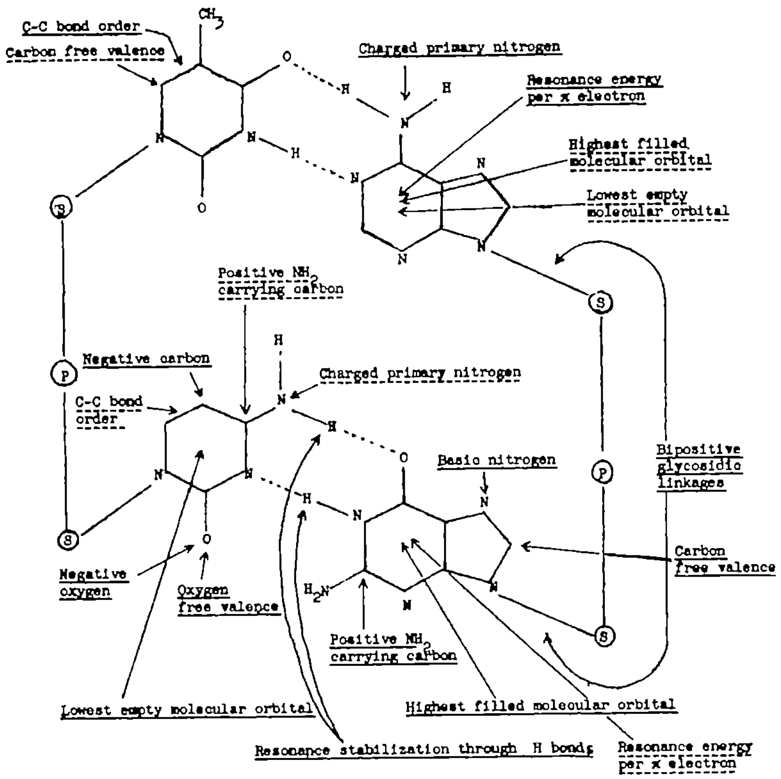
SUBMOLECULAR STRUCTURE OF THE NUCLEIC ACIDS

By Prof. BERNARD PULLMAN and ALBERTE PULLMAN

Institut de Biologie Physico-Chimique, Université de Paris, 13 rue Pierre Curie, Paris 5e

THE determination of the molecular structure of nucleic acids, which reveals the nature and mutual arrangement of the molecular species forming the giant polymers, is one of the most important achievements of modern biochemistry. The next logical step is the determination of the sub-molecular structure of these acids, which reveals the electronic structure of the constituents and the nature of the bonds which unite them. The establishment of the principal features of this sub-molecular structure should provide the proper basis for the understanding of the essential chemical, physico-chemical and biochemical properties of the nucleic acids.

Among the methods available for this investigation are the theoretical procedures of quantum chemistry, such as the valence bond or the molecular orbital



C-C bond order
Carbon free valence

methods. This last method, in particular, has been shown in recent years to be of great value for the study of the electronic structure of biochemicals and of the mechanism, at the electronic level, of biochemical processes. It has been applied extensively, in our laboratory, to the detailed investigation of the electronic aspects of the structure of the nucleic acids and especially cf that of their purine and pyrimidine bases.

This work enables the determination of the values of the essential energetic and electronic indexes characteristic of the bases or of their constituent atoms or groups of atoms. It thus also renders possible the determination of the sites at which any particular index has its most significant value. Consequently, it enables the establishment of correlations between these outstanding values of the indexes and the essential chemical and physico-chemical properties of the nucleic acids.

The principal results obtained are summarized in Table 1.

A more pictorial representation of these general results is given in Figs. 1 and 2. They contain the fundamental base pairs as present in the nucleic acids (S = sugar, P = phosphate). Fig. 1 indicates the sites at which the essential theoretical indexes of electronic structure possess their most significant values. In fact, the indexes are underlined by a heavy line when placed at the site of their most significant value and by a broken line at their next most important site.

In Fig. 2, the same thing has been done for the different chemical or physico-chemical properties determined by these indexes. In some cases, indexes or properties have been indicated on Figs. 1 and 2 without being underlined. This signifies that these indexes or properties are important characteristics of the corresponding bases, but that it is not possible to ascertain and compare their relative values in the different units.

The advantage of tne schematic representation given in Figs. 1 and 2 is that it enables a very quick localization of the principal reactive centres of nucleic acids towards given types of reagents.

Fig. 2. Principal chemical and physico-chemical properties of the nitrogenous bases of the nucleic acids

Table 1, FUNDAMENTAL ELECTRONIC INDEXES AND OUTSTANDING CHEMICAL AND PHYSICO-CHEMICAL PROPERTIES OF THE NUCLEIC ACIDS

The electronic index	Its manifestation
Resonance energy. The greatest resonance energy per π electron is that of the adenine ring. The next one is that of guanine Resonance stabilization through hydrogen bonds is greater for the guanine-cytosine pair than for the adenine-thymine pair[1,2].	Resistance of purines and in particular of adenine to ionizing and ultra-violet radiations[3]. Higher temperature of denaturation of nucleic acids rich in guanine-cytosine pair, than of those rich in adenine-thymine pair[3].
Highest filled molecular orbital. The highest filled molecular orbital is the highest in guanine followed by adenine[4,5].	The electron donor properties of purines, visible in their tendency to form charge-transfer complexes with different electron acceptors[4,5].
Lowest empty molecular orbital. The lowest empty molecular orbital is the lowest in cytosine, followed by adenine[4,6].	The electron acceptor properties of these two bases, visible in their tendency to trap electrons[6].
Basicity of ring nitrogens. In the nucleic acids the most basic nitrogen is predicted to be N_7 of guanine. In adenine the essential basic centre should be N_1 (in nucleic acid adenine it may be N_7)[1,2].	Protonation and alkylation by alkylating agents occur at N_7 of guanine and N_1 of adenine[7-9]. N-oxidation occurs at N_1 of adenine[10]. Alkylation of nucleic acids by alkylating agents occurs essentially at N_7 of guanine[11-13]. The principal site of chelation by metals is between N_7 and the O of guanine[14].
Charge of the primary amino-nitrogen. Because of the delocalization of their lone pairs the nitrogens of the NH_2 groups are formally positive. The most charged among them (the less positive) is that of adenine, followed by that of cytosine[1].	Direct alkyl substitution at the amino-group and the reaction with formaldehyde occur essentially on the NH_2 groups of adenine, followed by that of cytosine[15-17].
Charge of the carbon atoms carrying the amino-groups. These carbon atoms are formally positive. The most positive among them is that of guanine, followed by that of cytosine.	Deamination of deoxyribonucleic acid by NO_2H occurs essentially on guanine, followed by cytosine[18].
Charge of the oxygen atoms. The most negative oxygen is that of cytosine[1].	The oxygen of cytosine may be the primary site of protonation of undenatured deoxyribonucleic acid[19].
Carbon-carbon bond order. The greatest C-C bond order is that of the 5-6 bond of thymine, followed by the 5-6 bond of cytosine[2].	Hydroperoxidation under the action of ionizing radiations and hydration upon photolysis occur essentially at the C_5–C_6 bond of thymine[2]. Permanganate oxidation occurs essentially at the C_5–C_6 bond of cytosine, followed by that of thymine[20].
Indexes of unsubstituted C atoms. C_8 of guanine has the greatest free valence, C_5 of cytosine the greatest formal negative charge[1,2].	Both carbons are sites of electrophilic substitutions[21].
Bipositivity of the C-N glycosidic linkage. The formal positive charge of the sugar carrying nitrogen and the bipositivity of the glycosidic linkage are greater for the purines than for the pyrimidines[22].	Preferential reactivity of the glycosidic linkages of the purines in enzymic or acidic hydrolysis[22] and towards mercaptoacetic acid and diphenylamine[23,24].

In this respect, one of the striking features of Fig. 2 is that none of the quoted reactions appears heavily underlined for the adenine ring. (It is only the transformations which are concerned with its extracyclic NH_2 group which appear as occurring with particular ease at that molecule.) The relatively great stability of adenine towards external agents of any type is thus immediately visible after a simple glance at Fig. 2. This impression is still substantiated by a glance at Fig. 1 on which the only characteristic of the adenine ring which deserves the heavy underlining is its relatively great resonance energy. The particular part played by adenine in biochemistry has been tentatively linked with its particularly pronounced thermodynamic and kinetic stability[3].

DETECTION OF LIVER PROTEINS IN CIRCULATING BLOOD

By DR. A. H. GORDON

National Institute for Medical Research, Mill Hill, London, N.W.7

THE release of proteins from rat liver during perfusion of this organ with rat blood[1] can be demonstrated by means of rabbit antiserum against a homogenate of whole rat liver using the gel precipitation method of Ouchterlony[2]. To avoid precipitation lines due to the rat plasma proteins, the antiserum was always adsorbed with rat plasma before use. When the antiserum was allowed to react with the liver homogenate against which it was formed, 8–10 lines were obtained. Under similar conditions, plasmas from blood which had been used for perfusion of a rat liver for 4–5 hr. gave 2–6 lines. As may be seen in Fig. 1, both the number and the intensity of the lines produced by plasmas from different liver perfusions varied very greatly. The experiment (Fig. 1) also shows immunological identity, or partial identity, between proteins of the liver homogenate and those liberated during perfusion of the rat liver.

Altogether, plasmas from thirteen perfusion experiments were examined by means of the antiserum. In eight of these, heparin was present as the anticoagulant. In three the freshly drawn blood was mixed with 0·167 vol. of 3·8 per cent sodium citrate. After centrifugation the plasma was clotted by the addition of calcium ions. The serum thus obtained was then re-mixed with the red cells. In the last two experiments no sodium citrate was used, the blood being centrifuged in plastic tubes, separated and the plasma allowed to clot. After removal of the fibrin the serum was re-mixed with the red cells. In the last five experiments the only fibrinogen or fibrin which can have been present will have been that formed by the liver during the course of the perfusion.

When heparin was used the precipitation lines formed by the antiserum as judged by eye, although very variable in intensity, were on average much heavier than those which were formed after addition of citrate and removal of fibrin. The two plasmas which appeared to contain the smallest amounts of solubilized liver protein were from experiments of the latter kind. On the other hand, in another experiment of this kind, heavier precipitation lines were observed. Both the plasmas which had been defibrinated and then used without added sodium citrate gave rather heavy precipitation lines with the antiserum. In one of these experiments the perfusion-rate fell progressively and, at the end, material which seemed to be fibrin was found adhering to the glassware. Although experimental conditions for the perfusion of rat livers which will completely prevent the solubilization of even small amounts of liver material have not yet been completely defined, the above results with defibrinated blood containing citrate suggest the usefulness of such media.

Because of the apparent readiness with which certain components appeared in the plasma during perfusion of the isolated liver, conditions which would lead to release of proteins from the liver *in vivo* were sought. Plasmas were examined from rats subjected to: (1) Repeated injection with large amounts of indian ink over four days (for details, see Freeman, Gordon and Humphrey[3]). (2) Anaphylaxis; a rat previously sensitized by means of hæmocyanin in Freund's adjuvant was injected intravenously with 2 mgm. of alum precipitated hæmocyanin. Two hours after the commencement of severe, but non-fatal anaphylaxis, the animal was bled. (3) Intravenous injection of the lipopolysaccharide endotoxin of *E. coli* 08 (from Prof. O. Westphal). Whereas no effect could be detected as a result of either of the first two treatments, plasma obtained 6 hr. after the injection of 1 mgm. of the endotoxin already yielded a single precipitation line. After a further 16 hr. the plasma from the same animal gave three lines. The rat which showed minimal signs of prostration was then killed. The liver showed many pale spots.

The identity or otherwise of the liver components released into the plasma *in vivo* by the endotoxin with those appearing after perfusion of a liver for several hours was also examined. In all experiments continuity of the precipitation lines formed between the antiserum and plasmas from each kind of experiment was observed. Apparently no components present in one plasma were completely absent from the other. On the other hand, large quantitative differences between certain components were noticeable.

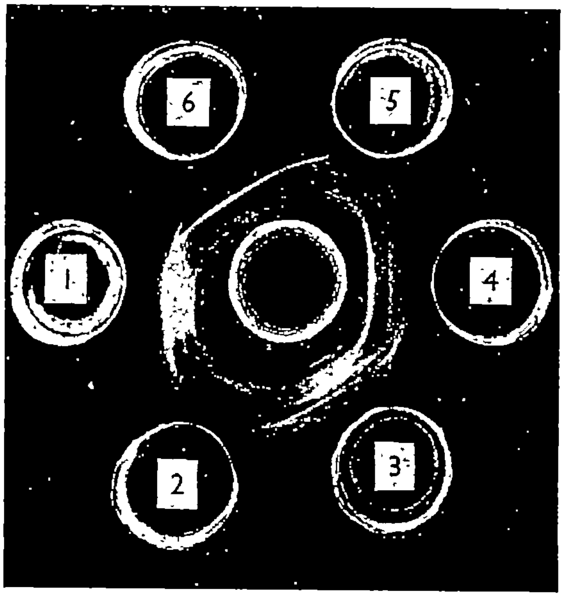

Fig. 1. Centre hole: antiserum produced in rabbits by injection of rat liver homogenate treated with Freund's adjuvant. The antiserum has been absorbed by subsequent addition of rat plasma. (1) and (3) Rat liver homogenate diluted with 9 vol. of saline; (5) rat liver homogenate diluted with 19 vol. of saline; (2) plasma from rat blood used for perfusion of a rat liver for 4 hr.; (4) plasma from rat blood used for perfusion of a rat liver for 5 hr.; (6) plasma from rat blood used for perfusion of a rat liver. For this perfusion the plasma protein concentration was raised to 104 mgm. per ml. Heparin was used in each of these perfusion experiments

In order to obtain information on the amount of material passing from the liver into the circulating blood during a perfusion experiment, comparison was made between the precipitation lines given with the antiserum by appropriate dilutions of a saline extract of rat liver and by samples of plasma from blood after use for perfusion. Appropriate dilutions of the liver extract and dilutions of the perfusion plasma were arranged alternately around a central well. By observing which samples gave precipitation lines of similar intensity and position, it was possible to estimate the dilution of liver extract containing amounts of particular liver components corresponding to those in the perfusion plasma.

Three samples of plasma taken at the end of three liver perfusion experiments were thus investigated. The first was from a perfusion in which heparin was present and in which the plasma protein concentration had been increased above normal. This plasma was found to contain at least 3·5 mgm. per ml. of liver protein. The two other plasmas, from experiments in which defibrinated blood containing sodium citrate had been used, gave 0·23 and 2·1 mgm. per ml., respectively. Considered in relation to the total weight of protein in the perfused liver, these figures indicate that at least 0·5–5 per cent of originally intracellular material had appeared in the circulating plasma.

I am very grateful to Dr. J. H. Humphrey for advice on the immunological methods used in the present work and for discussion of the problem.

AFFINITY OF ORGANIC COMPOUNDS FOR FREE ELECTRONS WITH THERMAL ENERGY: ITS POSSIBLE SIGNIFICANCE IN BIOLOGY

By DR. J. E. LOVELOCK

National Institute for Medical Research, Mill Hill, London, N.W.7

MANY molecular species react with free electrons to form stable negative ions. In the classical physical researches on the behaviour of free electrons in gases[1-3], the study of negative-ion formation was restricted to a few simple substances such as water, oxygen and the halogens. More recently, a technique has been developed for observing the electron affinity of volatile organic substances generally[4]; this technique was primarily intended as a qualitative analytical method for the identification of minute quantities of volatile organic compounds. It was based on the observation that the electron affinity of a homologous series of compounds was determined principally by the affinity of the common functional group and was relatively independent of the hydrocarbon moiety. The establishment of this method requires measurement of the electron affinities of a wide range of compounds at various electron energies; this is a lengthy task and not yet completed. In the course of this investigation it has been observed that the affinities of compounds for electrons with thermal energies are frequently associated with their biological activity, particularly in those systems thought to involve electron transport. For example, among the few simple aliphatic compounds with an extreme affinity for electrons are the intermediates on the oxidation pathways of the living cell, such as pyruvate and fumarate. The potential interest of this and other similar comparisons between biological activity and electron affinity encouraged the preliminary report which follows. It describes briefly the methods used to measure the affinities of organic substances for thermal electrons and includes a discussion of the general problem of electron transport in the living cell in the light of these new measurements.

Physical basis and experimental method. Free electrons and molecules react to form stable negative ions by either of the two following processes:

$$e^- + AB = (AB)^- + \text{energy} \qquad (1)$$

$$e^- + AB = A + B^- \pm \text{energy} \qquad (2)$$

In the first reaction, the energy released may escape as radiation or be shared with other molecules during subsequent collisions. The energy balance of the second reaction is determined principally by the following factors: the relative kinetic energies of the reactants before and after collision, the energy released by the formation of a negative ion from a constituent atom or radical of the compound and the energy released or required to dissociate the molecule. Whichever of these reactions takes place, electrons are lost and stable negative ions formed. The probability of electron capture by a given compound depends on the elementary composition and structure of its molecules and on the kinetic energy of the colliding electrons. In the analytical application, it is convenient to observe the spectrum of affinity of a given molecular species at different electron energies. In the present work the affinities of different substances were observed using electrons in thermal equilibrium with gas mixtures at temperatures of 20°–200° C. This range of energies is presumably similar to that of free electrons, should they so exist, in biological systems.

The apparatus used is illustrated as a schematic diagram (Fig. 1). It consisted of a plane parallel ionization chamber with an electrode separation of 1 cm., and was identical in construction to that described for another purpose[5]. The chamber was swept continuously by a stream of clean dry argon containing 0·3 per cent of hydrogen at a rate of 100–1,000 ml. per min. at atmospheric pressure. Electrons were set free in the chamber by means of soft β-radiation from a sheet of metal coated with a thin layer of titanium tritide; this radiation source also served as the cathode of the chamber. The density of free electrons in the chamber was measured by applying to the anode, every 10 μsec., a rectangular pulse 50 V. in amplitude and 0·5 μsec. in duration. The duration of this sampling pulse was chosen to be just sufficient to collect all the electrons set free in the chamber; in other words, capable of withdrawing a saturation current from the chamber. Such a pulse duration was, however, much too short to collect any of the relatively immobile negative molecular ions. The contribution to the total current-flow of electrons liberated during the application of the pulse was only 5 per cent; the loss of electrons, when vapours capable of capturing them were present in the chamber, was therefore observed effectively under field-free conditions and when the energy of the electrons present was thermal. The vapours of the test substances were introduced into the gas stream flowing to the chamber after their passage through an efficient 100-ft. capillary tube chromatograph column. This precaution was found essential since few of the substances tested were free of electron-capturing contaminants. The concentration of vapour in the gas stream was measured by means of a photo-ionization detector[6] connected in parallel with the chamber for observing electron capture. The current-flow from the two ionization chambers was amplified by electrometer amplifiers and recorded using two separate potentiometric recorders.

Fig. 2 illustrates a typical measurement in which the emergence of several compounds in sequence from the chromatograph column is displayed as chromato-

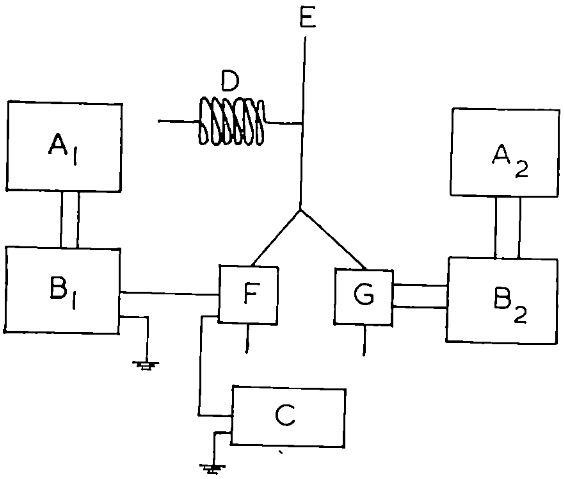

Fig. 1. Schematic diagram of the apparatus used for the measurement of relative electron affinities. A_1 and A_2 potentiometric recorders, B_1 and B_2 electrometer amplifiers, C a pulse generator, D a capillary tube chromatograph column, E inlet for diluent gas, F the ionization chamber for observing electron capture and G a photo-ionization detector for the measurement of concentration of test vapour

grams. The lower chromatogram shows the vapour concentrations of the test substances and the upper shows the extent of electron capture. The small vapour concentrations of the test substances, ethyl pyruvate and dimethyl fumarate, are seen to capture electrons much more readily than the large vapour concentration of the reference substance, chlorobenzene. Also, the test substance, diethyl succinate, is seen to have little or no affinity for electrons. The relative electron affinities of the different substances tested were compared in terms of the ratio of the change of current in the two ionization chambers and are expressed always as relative to the reference standard, chlorobenzene. Whenever possible, the quantity of test substance used was adjusted so that the change in current in the electron-capture chamber did not exceed 10 per cent of the total current. Above this value the change of current is no longer linearly related to vapour concentration. To meet this need, quantities of between 10^{-6} and 10^{-9} gm. were applied to the column. It must be emphasized that the electron affinities reported here may be as much as 30 per cent in error. Uncertainties arise principally in the measurement of vapour concentration. It is not yet possible to apply precisely known amounts of test substances to the efficient capillary tube column. Also, the response of the photo-ionization detector used to measure vapour concentration is not yet known with precision. This detector was chosen for this application because it is the only available sensitive ionization detector the response of which is not adversely affected by substances with a high affinity for free electrons.

Relative electron affinities of the substances tested. Table 1 lists the electron affinities, relative to chlorobenzene as unity, of the strongly electron-attracting substances tested; also shown are the principal electron-attracting substituents or structures of these substances and the electron affinities of comparable weakly attracting compounds.

The great majority of simple aliphatic organic compounds possess a slight or negligible affinity for free electrons of thermal energy. Those which do capture electrons strongly have one or more of the following structures or substituents in their molecules, which henceforth will be called 'electrophores': (1) —CO.CO—, (2) —CO.CH : CH.CO—, (3) the quinone structure, (4) $—NO_2$, (5) $—X$, where X is one or more halogen atoms. With substitution by halogens affinities fall in the order: $I > Br > Cl > F$; multiple substitution by halogen- or nitro-groups greatly enhances the affinity for electrons.

It is probable that other more or less complex structures can function as electrophores. Thus, although simple conjugated and aromatic hydrocarbons such as butadiene, benzene, naphthalene and phenanthrene show little affinity, more complex conjugated hydrocarbons, including *cyclo*-octatetrene, azulene, diphenyl butadiene and anthracene, all show a marked affinity for free electrons. It appears also that [—CO.] in the electrophores listed above can be replaced by a phenyl radical without great loss of affinity; a substitution of nitrogen in place of carbon can also be made. It must be emphasized, however, that affinity of a high order, greater than ten, is rare among the simpler organic compounds. An affinity of this order has not been found during the examination of 430 members of the following classes of organic compounds: saturated, ethenoid and ethinoid hydrocarbons, ethers, esters, alcohols, carboxylic acids, aldehydes, ketones, nitriles, amines and, with the exceptions listed in Table 1, compounds with two or more of these groups. Although weakly attractive to thermal electrons, the compounds just listed do possess a sufficient affinity for analytical purposes.

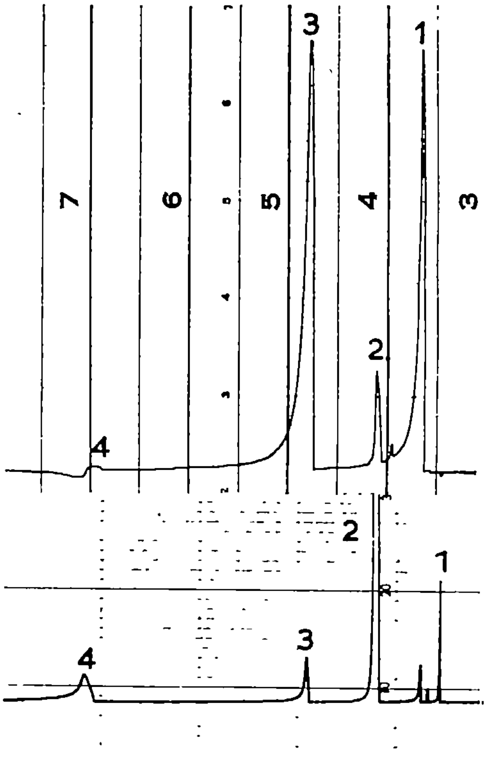

Fig. 2. Measurement of electron affinity using the apparatus indicated in Fig. 1. The lower chromatogram shows the concentrations of vapours emerging from the chromatograph column, the upper chromatogram the capture of electrons by the same vapours measured simultaneously. The test substances are ethyl pyruvate (1), chlorobenzene (2), dimethyl fumarate (3) and diethyl succinate (4)

Table 1. AFFINITIES FOR THERMAL ELECTRONS OF COMPOUNDS OF BIOLOGICAL INTEREST

All values are relative to the electron affinity of chlorobenzene, which is taken to be unity

Compounds with high electron affinity	Electrophore	Affinity	Compounds with low electron affinity	Affinity
Ethyl pyruvate	—CO.CO—	1,700	Ethyl acetate	< 0 01
Diacetyl	—CO.CO—	2,000	Acetylacetone	1·2
Dimethyl oxalacetate	—CO.CO—	1,300	Ethyl acetoacetate	0·7
Diethyl fumarate	—CO CH : CH CO—	1,500	Ethyl acrylate	0·1
Diethyl maleate	—CO CH : CH CO—	1,700	Diethyl malate	0·01
			Diethyl succinate	< 0·01
Quinone	*Q*	5,000		
Dimethylnaphthaquinone	*Q*	4,100	Hydroquinone	0·1
Benzaldehyde	—CO *P*	48	Benzyl alcohol	0·05
Cinnamaldehyde	—CO CH : CH *P*	310		
cis-Stilbene	*P* CH : CH *P*	1	Styrene	< 0·01
trans-Stilbene	*P* CH · CH.*P*	4		
Acetamide	—CO NH.	12	Methyl amine	0·01
Azobenzene	*P*.N : N.*P*	9	Aniline	0 1
Diacetyldihydropyridine	*Q*	4,000	Pyridine	0 02
Anthracene		12	Phenanthrene	0 05
Azulene		340	Naphthalene	< 0 01
Cyclo-octatetrene		210	Cyclopentadiene	< 0·01
Carbon tetrachloride	—Cl	7,000	Ethane	< 0·01
Chloroform	—Cl	800		
Hexachlorobenzene	—Cl	1,100	Benzene	< 0 01
Chlorobenzene	—Cl	1		
Bromobenzene	—Br	6		
Iodobenzene	—I	870		
Nitrobenzene	—NO_2	390		
Dinitrophenol	—NO_2	1,450		

P, phenyl radical. *Q*, quinone structure.

At present no information is available concerning the end products of the reaction between the compounds tested and free electrons. It is probable, however, that capture is followed by dissociation with the halogen- and nitro-compounds. The hydrocarbons and perhaps some CHO compounds are, on the other hand, likely to form stable negative molecular ions.

Relevance to biological systems. It has been suggested that protein may show semi-conducting properties important in its normal function[7]. More recently, evidence has become available to suggest that in photosynthesis[8,9] and in the transfer of energy in mitochondria[10,11], free electrons play an important part. In the light of these suggestions it is of interest that the electrophores, —CO.CO—, —CO.CH : CH.CO— and the quinone structure are all closely associated with those systems thought to be important in electron transfer. Thus, in the process of oxidative phosphorylation proceeding from pyruvate through the Krebs cycle to carbon dioxide each alternate intermediate has one or other of the two electrophores, —CO.CO— and —CO.CH : CH.CO—. The first is found in pyruvate, oxalacetate, and ketoglutarate; the second in *cis*-aconitate and in fumarate. The remaining intermediates are found in the form of their esters, or would be thought to have but little affinity for free electrons. The 'inert' intermediates, including succinate, malate, acetate, citrate and *iso*citrate, are always interposed between the electron-attracting intermediates. Two other substances thought to be important in the transport of electrons in the living cell are coenzyme *Q* and diphosphopyridine nucleotide (DPN). The former has the quinone electrophore; it is conceivable that the structure of DPN includes an electrophore as yet unidentified.

The presence in the electron transport system of the living cell of an ordered distribution of so many of the few simple organic substances likely to have a high affinity for free electrons seems to be more than coincidental. It is also remarkable that among the few remaining substances with a similar high affinity for free electrons are several which are able to disturb the process of oxidative phosphorylation, such as dinitrophenol and certain halogen-containing compounds. The significance of the association between electron affinity and biological function depends on the assumption that the electrophores are as active in the relevant compounds in their natural state as they are in the volatile esters tested. If this assumption is justified, then the observations suggest the following unifying hypothesis: electron transport in the living cell proceeds through an ordered sequence of reversible electron traps. The introduction of foreign, especially irreversible, trapping agents is harmful because of their ability to remove electrons from the normal sequence. The term reversible trap refers to a compound which after capturing an electron changes either physically or chemically to a second compound the affinity of which is slight, and so releases the electron for the next trap in the sequence. To illustrate this point, fumarate could be considered to capture an electron and the negative fumarate ion then reacts with water to form a malate negative ion; the weak affinity of malate for electrons would encourage their transfer to the next trap in the sequence, possibly DPN.

The hypothesis that electron trapping in the living cell is a purposeful process offers explanations for a number of apparently intractable problems in biological electron transport. A few of these problems, particularly those concerned with the mechanism of action of toxic substances able to disturb the normal process of electron transport, are briefly discussed as follows:

In descriptions of the mechanism of photosynthesis, it has repeatedly been stressed that some process is required to explain the rapid removal of primary electrons before they can recombine with the positive charges simultaneously produced by photon impact[12]. The trapping mechanism just described would meet this need.

The volatility of the thyroid hormones is too low to measure their electron affinity by the methods just described. It is tolerably certain, however, that these compounds, which contain three or more iodine atoms, are potent electron traps. The possibility that the thyroid hormones owe their ability to moderate the process of oxidative metabolism to their high affinity for free electrons is supported by the following circumstantial evidence: the biological activities of trichloro-, tribromo- and tri-iodo-thyronine[13] are respectively: 1, 37 and 420. The electron affinities of chloro, bromo- and iodo-benzene are respectively: 1, 6, 370. Although the structures of the thyronines are very different from those of the halogen-substituted benzenes, the comparison is justified by the fact that the electron affinity conferred by halogen substitution is frequently independent of the nature of the molecule substituted; provided, of course, no other electrophores are also present. The resemblance between the biological activity of the thyroid hormones and that of dinitrophenol is further evidence in support of this interpretation.

Another reaction in biochemistry thought for some time to involve electron transfer is that between carcinogenic hydrocarbons and protein. A stumbling block to the understanding of the nature of this reaction has been the persistently held assumption that the hydrocarbon is the donor and the protein the acceptor of electrons; this has been difficult to reconcile with theory or observation. It was suggested tentatively[14,15] that these difficulties could be resolved if the hydrocarbon were in fact the acceptor of electrons. The unpopularity of the notion of a hydrocarbon so behaving in that way seems to have prevented the general acceptance of the suggestion. However, as shown in Table 1, complex hydrocarbons are very ready to function as electron acceptors. Because of their slight volatility, it has not yet been possible to test the carcinogenic hydrocarbons themselves, although it is of interest that stilbene and azobenzene both are able to capture electrons and give rise to simple derivatives with carcinogenic activity.

In general, where a similar toxic action is shared by compounds differing only in substitution with halogen- or nitro-groups, and where a disturbance of electron transport is thought to occur, then the toxicity of the compounds could be due to their ability to trap electrons. One important difference between normal intermediates which can trap electrons and the toxic substances could be in the type of reaction which takes place. Trapping of electrons is potentially most harmful when it is irreversible; in these circumstances, the potential energy of the captured electron may be completely removed from the system. Furthermore, if dissociative capture occurs, and it is likely to occur with halogen- and nitro-compounds, then a highly reactive and potentially harmful free-radical may be formed. In addition to those classes of toxic agent already mentioned, other substances which may function in a similar way include halogenated insecticides, inhibitors of plant growth, certain fungistatic iodo- and nitro-compounds[16] and certain antibiotics such as chloramphenicol. Some of the limitations of the evidence provided from measurements of electron affinity arise from the need to conduct the observations on volatile derivatives in the gas phase. There is no reason in principle why similar measurements to those described should not be made in the liquid or even solid phases. The solution of the practical problems in this direction will greatly extend the range of measurement of this potentially important molecular property, and perhaps provide the evidence necessary for the confirmation or denial of the hypotheses outlined in this article.

I am indebted to my colleagues T. Nash and N. L. Gregory for the stimulus of their suggestions.

AGGREGATION, VARIANCE AND THE MEAN

By L. R. TAYLOR
Department of Entomology, Rothamsted Experimental Station, Harpenden, Herts

IN populations where the individuals are distributed at random, that is, are independent of each other, the variance (s^2) at each population density is equal to the mean (m). Individuals in natural populations are not, however, independent of each other; mutual attraction leads to aggregation which makes variance more than the mean ($s^2 > m$), and mutual repulsion leads to regularity which makes variance less than the mean. Hence, in Nature, true randomness is only one of a continuous series of possible distributions (both in a spatial and a statistical sense) from regular to highly aggregated, and is consequently rare.

This property of natural populations, to show some degree of aggregation, is commonly thought to be highly specific; for example, soil zoologists know that leather-jackets are 'more highly aggregated' than wireworms, yet the meaning of this is intangible, because no consistent measure of aggregation is at present available. In addition, many kinds of statistical analysis require that the variance should be made independent of the mean and there is no rational transformation available covering all grades of aggregation. Aggregation has been measured most widely using k in the expression:

$$s^2 = m + km^2 \qquad (1)$$

derived from the negative binomial distribution. Unfortunately k is not always independent of m (ref. 5), and it is plainly desirable that an index of population structure should be the same at different population densities, unless some actual change in behaviour is involved.

In all the sets of samples I have examined, variance appears to be related to the mean by a simple power law; variance is proportional to a fractional power of the mean:

$$s^2 = am^b \qquad (2)$$

where a and b are characteristic of the population in question. This is most clearly demonstrated by a log × log plot of s^2 on m as in Fig. 1, which includes some classic population surveys. Table 1 gives a and b for these and other populations, namely, virus lesions, macro-zooplankton, worms and symphylids in soil, insects in soil, on plants and in the air, mites on leaves, ticks on sheep and fish in the sea.

* Units combined to cover areas varying in size from 1 sq. ft. to 100 sq. ft. † Larvæ/stalk × infested stalks/100 : this introduces some bias in the variances.

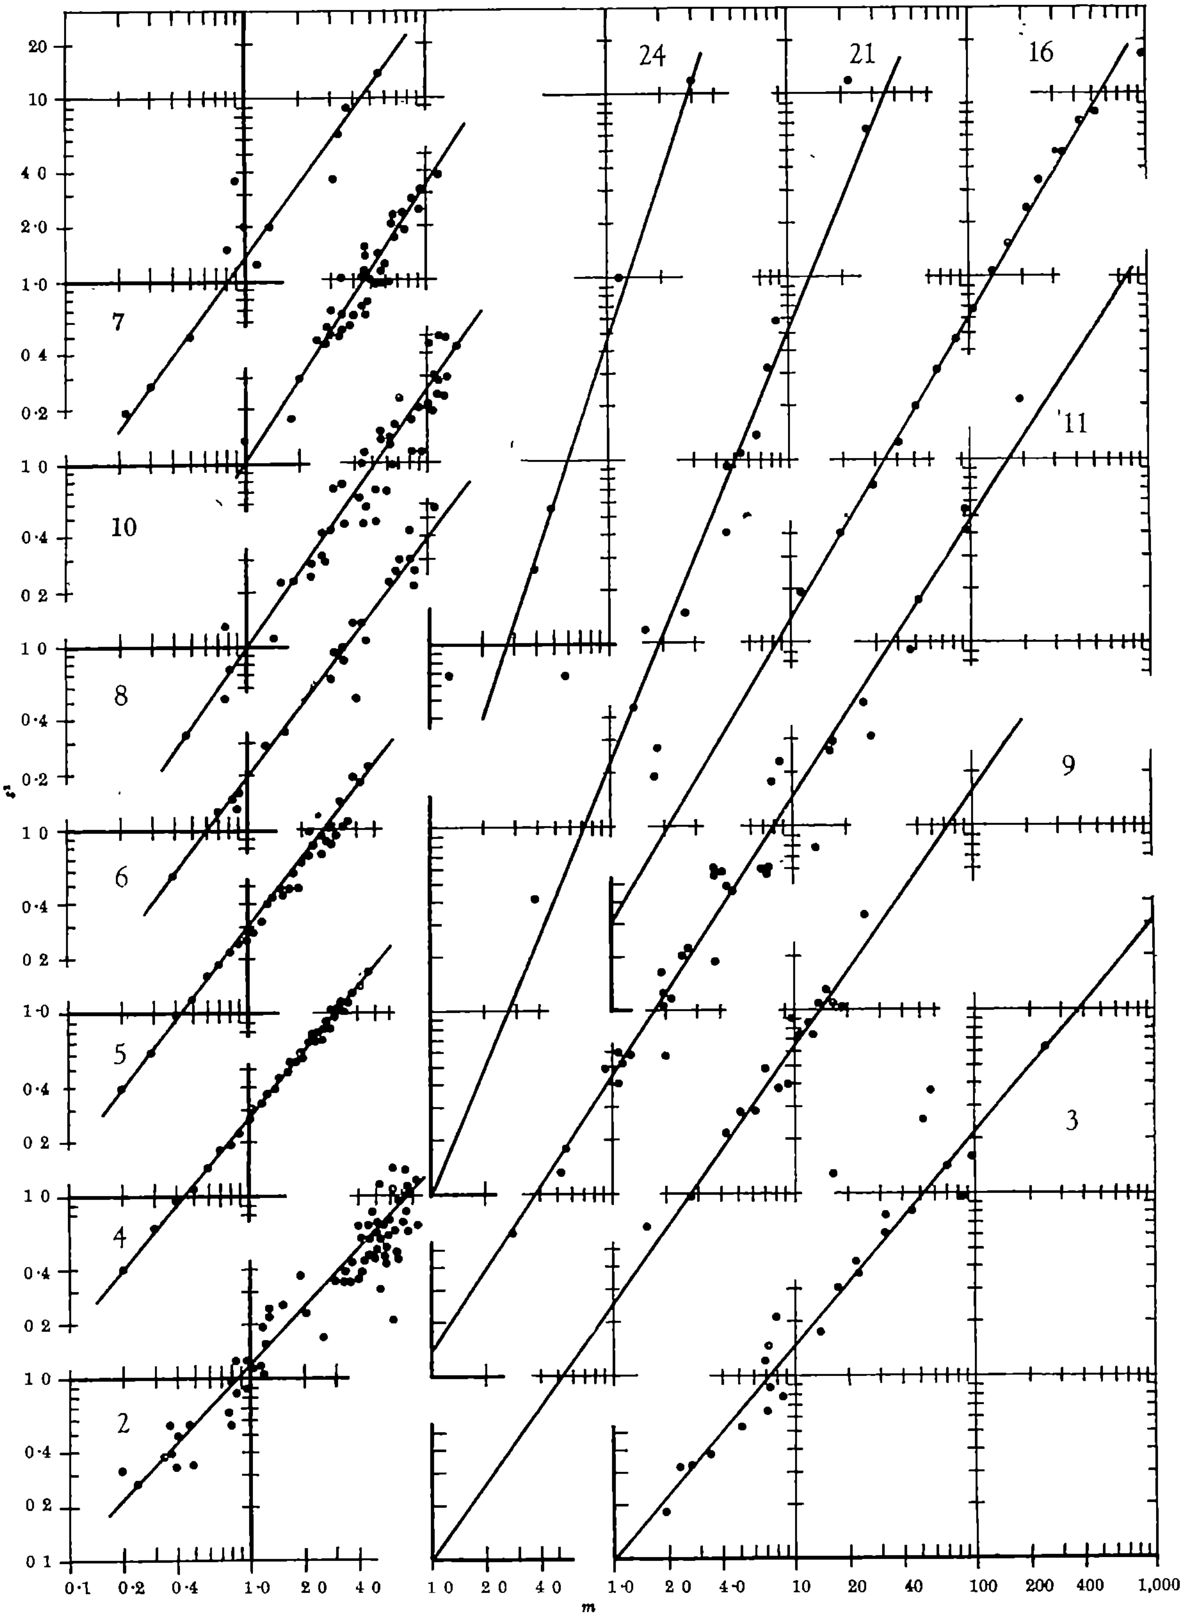

Fig. 1. Variance × mean on log × log scale for material numbered as in Table 1. The axes (heavy lines) are staggered to accommodate as much material as possible

a is evidently largely, possibly wholly, a sampling or computing factor, depending upon the size of sampling unit and on which estimate of variance is used; this was not clearly stated in some of the analyses. b appears to be a true population statistic, an 'index of aggregation' describing an intrinsic property of the organisms concerned and with a continuous graduation from near-regular ($b \rightarrow 0$), through random ($b = 1$) to highly aggregated ($b \rightarrow \infty$).

To use the analysis of variance technique raw data must first be transformed to make s^2 independent of m. Using expression (2), the general transformation:

$$f(x) = Q\int m^{-b/2}\,\mathrm{d}m \qquad (3)$$

where Q is a constant, is obtained. Integration gives a square root transformation when $b = 1$ and, logically, a logarithmic transformation when $b = 2$, as are commonly used; for highly aggregated populations ($b > 2$) it gives a negative fractional power, for example, a reciprocal, as is appropriate to the powerful transformation required.

The power law appears to hold good down to low densities ($m < 1$) in the material examined here. This implies that populations aggregated at high density tend to become regular when density diminishes, and vice versa; the law may break down eventually or, alternatively, perhaps the concept of aggregation ($s^2 > m$) is inappropriate at these low densities. In any event samples consisting mainly of 0's and 1's are likely to need special statistical treatment.

SURFACE ORIENTATION AND FRICTION OF GRAPHITE, GRAPHITIC CARBON AND NON-GRAPHITIC CARBON

By Dr. J. W. MIDGLEY and D. G. TEER

Mechanical Engineering Laboratory, English Electric Co. Ltd., Whetstone, near Leicester

THE effect, if any, of surface orientation on the friction of various carbons has not yet been clearly established. Indeed, previous reports on the orientation developed by rubbing are conflicting[1-4]. To clarify the position and hence to improve our understanding of the mechanism of the friction of wear of these materials, an attempt has been made to provide fresh evidence, notably by a comparison of the behaviour of a carbon with a very low degree of graphitization[5] with graphite and graphitic carbon These materials have been rubbed unidirectionally and the surface orientation studied by electron diffraction.

When graphite or highly graphitic carbon is rubbed unidirectionally against itself, mild steel or paper, the surface crystallites rapidly become orientated with their (00l) basal planes at a small angle (5–10°) to the surface with the basal plane normals tilted against the direction of motion of the opposing surface, as shown by the electron diffraction pattern of Fig. 1. The deviation of this orientation from the parallel orientation previously reported[1-3] is small, but nevertheless significant, since, as the coefficient of friction is in the range 0 1–0·2 the present texture is consistent with a compression texture with its axis parallel to the resultant of the normal reaction and the friction forces. Similar textures have been recently reported by Porgess and Wilman[6] to be developed by graphite when abraded with emery.

The following factors could contribute to the formation of this texture: (*a*) basal plane slip; (*b*) the plate-like shape of the crystallites; (*c*) preferential removal of crystallites in other orientations.

Concerning the first of these, an electron microscope study has confirmed that, as previously reported

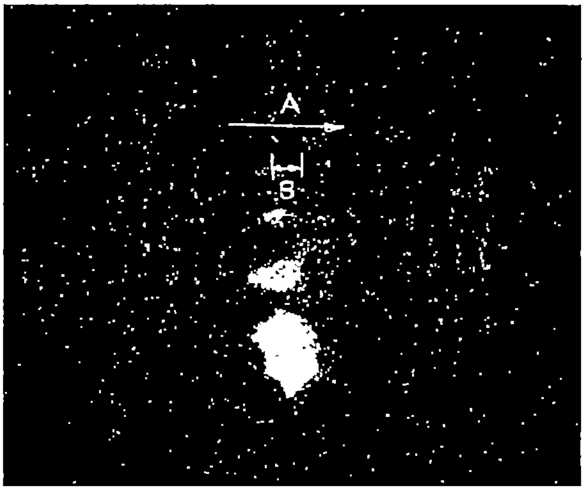

Fig. 1. Electron diffraction pattern of rubbed graphitic carbon. *A*, direction of motion of opposing surface; *B*, basal plane normals make angle of 5–10° to the surface normal

by Williamson[7] and others, basal plane dislocations are present in graphite. Furthermore, we have noted that rubbing gives rise to an extra ring in the electron diffraction patterns which coincides with the normally forbidden (111) ring and this is interpreted as arising from the presence of diffracting crystallites which have been reduced by shear to a few atom planes in the [001] direction[8]. Deacon and Goodman[3] have suggested that in the case of rubbed films of colloidal graphite the plate-like shape of the crystallites plays a decisive part in determining the surface orientation, and we believe that the shape of the crystallites will almost certainly contribute to the observed orientation on massive graphite and graphitic carbon. Finally, it is considered that the development of this preferred orientation is assisted by the preferential removal of crystallites, the basal plane normals of which are tilted in the direction of motion of the opposing surface, for such crystallites will tend to interlock and be plucked out by asperities on the opposing moving surface. The last mechanism, however, could not by itself form the observed orientation on graphite and graphitic carbon, and it is considered that with these materials the first two mechanisms are the most important.

Non-graphitic carbon behaves differently. A surface orientation does develop, but much more slowly than with graphite, and it eventually consists of crystallites the basal plane normals of which are tilted at all angles against the direction of motion of the opposing surface, as shown by the electron diffraction pattern of Fig. 2. This orientation is believed to arise from the preferential removal or wearing away of crystallites with unfavourable orientations. The structure of non-graphitic carbon does not encourage basal plane slip as there is not a unique slip direction, and the crystallite shape does not appear to play a significant part.

Simple compression tests have been employed to verify that non-graphitic carbon does not form a compression texture even when subject to a much higher compressive stress than that necessary to cause graphitic carbon to form the well-known (00*l*) compression texture. This result is in accordance with those of Bacon[9] and Ali, Fitzer and Ragoss[10], and confirms that with non-graphitic carbon the crystallite shape and slip mechanism are likely to be of minor importance in the formation of the rubbing texture.

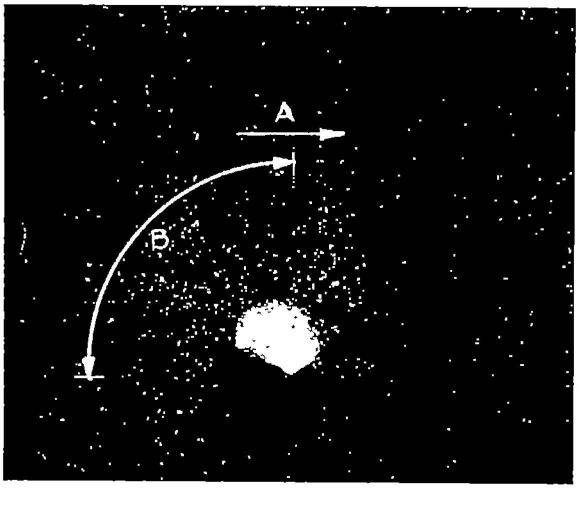

Fig. 2. Electron diffraction pattern of rubbed non-graphitic carbon. *A*, direction of motion of opposing surface; *B*, basal plane normals in this quadrant only

It has been found that the coefficient of friction of non-graphitic carbon is as low as that of graphitic carbon, and yet this low friction is achieved even though a high percentage of the surface crystallites have their basal planes at large angles to the surface. Thus, a parallel orientation is not necessary for the production of a low friction with non-graphitic carbon, and there is no reason to suppose that this is not also true for graphite and graphitic carbon. However, a temporary increase of friction of both graphitic and non-graphitic carbon has been found to occur after reversal of the rubbing direction as shown in Fig. 3 (a similar effect has been mentioned by Fullam and Savage[4]). This increase of friction is considered to arise from the interlocking of those crystallites which are in unfavourable orientations after reversal, as with fibres rubbed against the direction of the scales on their surface (cf. Bowden and Tabor[11]). The mechanism of the friction and wear of graphitic and non-graphitic carbon crystallites with unfavourable orientations is thought to be abrasion rather than intercrystallite attraction.

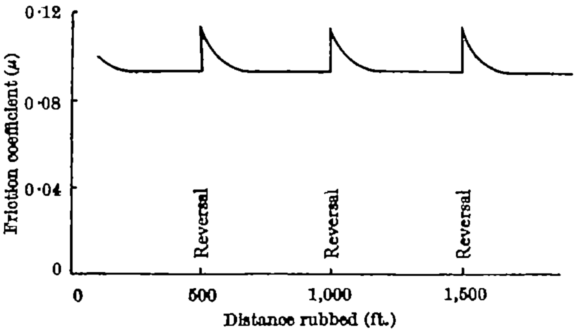

Fig. 3. Increase of friction on reversal of rubbing direction

The present results are interpreted as giving considerable evidence in support of the view that the low friction of graphite and non-graphitic carbon is due to the low adhesion between crystallites[3] rather than to low shear strength[12].

A more detailed account of this work will be published elsewhere.

We are indebted to the Directors of the English Electric Co., Ltd., for permission to publish this communication. We also wish to thank Mr. R. Brew, who took some of the electron diffraction patterns, and Mr. R. Suhr, who supplied X-ray results on the compression textures.

ASTROPHYSICS

Rotation Period of the Artificial Satellite 1958δ1

RECENTLY, C. R. Faulkner[1] has suggested that changes of the rotation of 1958δ1, especially the decrease of the period during the last days in November 1958, may be explained in part by a strong westerly wind in the upper atmosphere.

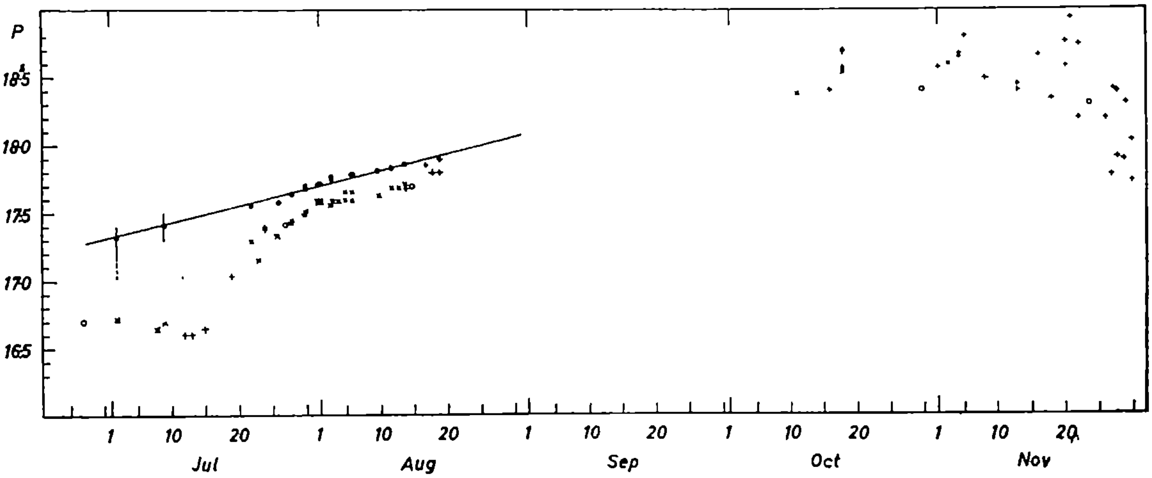

Fig. 1. Period of rotation of 1958δ1. ⍿, Period of rotation with limits of error (October 18 : two possible solutions). ×, Period of scintillation from observations in Babelsberg and Potsdam. ○, Uncertain (November 23 . amplitude of light variation very small). +, Scintillation period from some other sources (ref. 7 and Tatum, J. B., private communication)

Consider first the influence of the rotation of the Earth's atmosphere on the speed of the rotation of the satellite. According to King-Hele[2], in the presence of atmospheric rotation, a factor F, which is 0·95 for 1958δ1, must be added to the aerodynamic force acting in the direction opposite to the velocity of the satellite. Similarly, the formula for the momentum, braking the rotation of the satellite[3], must be altered to the form (neglecting for a moment the component of the atmospheric rotation acting vertically to the path of the satellite):

$$D_B = \text{const.}\, \rho B L^3 \left[v\sqrt{F}\, \omega \mathbf{F}_1 - \frac{1}{3H} v^2 F\, \mathbf{F}_2 \cos \angle B \right] \quad (1)$$

This formula holds for a long cylinder of diameter B and length L ($L \gg B$). $\mathbf{F}_1$ and $\mathbf{F}_2$ are the drag-coefficients for rotation; they change by a maximum of 24 per cent, depending on the position of the rotational axis. H is the scale-height of the atmosphere. $\angle B$ denotes the angle between the pole of rotation and the pole of the orbit of the satellite. The introduction of the factor F in D_B changes this momentum to approximately 0·97 (for 1958δ1) of its former value.

Further, the rotation of the satellite will be influenced by the component of the rotational velocity of the atmosphere, acting vertically to the orbit of the satellite:

$$v_\perp = r_p\, \omega_e \sqrt{(\cos^2\varphi - \cos^2 i)}$$

Here ω_e means the Earth's angular velocity, r_p is the distance from the Earth's centre at perigee, i the inclination of the orbit to the equator. This component is of influence only in the vicinity of the equator ($\varphi = 0$), but even there, its contribution is limited to a maximum of 1·5 per cent of the momentum given by (1), because its action is equivalent to a small displacement (max. ~4°) of the position of the rotational axis with respect to the orbit of the satellite. This causes the coefficients $\mathbf{F}_1$ and $\mathbf{F}_2$ in (1) to change slightly (by maximum of 1·5 per cent as mentioned above).

Because of the smallness of all these factors, we think it impossible, using the observations so far available, to prove that the rotating atmosphere can have an effect on the rotation of satellites, and even less provide evidence of strong winds in the upper atmosphere. From the theoretical point of view, an acceleration of the rotation as indicated in the last days of November (see Fig. 1) is only possible for periods exceeding about 100 sec., provided the position of the rotation axis is favourable.

It is quite certain that the observed period of flashing of 1958δ1 is not identical with its true rotation period[4,5]. An attempt to calculate the real period from the observed flashes has shown[6] that very great deviations up to about 0·9 sec. from the true period may occur, especially if the distance of the satellite from the observer is small (for example, July 1–25, 1958). A similar effect may be present at the end of November. Therefore it is not necessary to explain the behaviour of the rocket at that time by a real acceleration of its rotation. Unfortunately, it was not possible for us to determine the true period from the known observations in November, because of the lack of a sufficient number of exactly known moments of single flashes.

[7] Moore, J. G., *Sky and Telescope*, 18, 88 (1958).

MY estimate of a decrease of 0·3 sec. in the rotation period (strictly the 'tumbling' period) is the residual effect, after making allowance for the difference between the flash period and the true rotation period Observing from the north of Scotland, I found that by November 27–28, 1958, the flash period had fallen to 8·95 sec. in transits across the south-west at about 0·8°/sec.

I think it is possible to show that only about half the decrease can be attributed to more rapid movement of the observers' line of sight, if it is assumed that the number of flash cycles could never be more than one greater than the actual number of 'tumbles'.

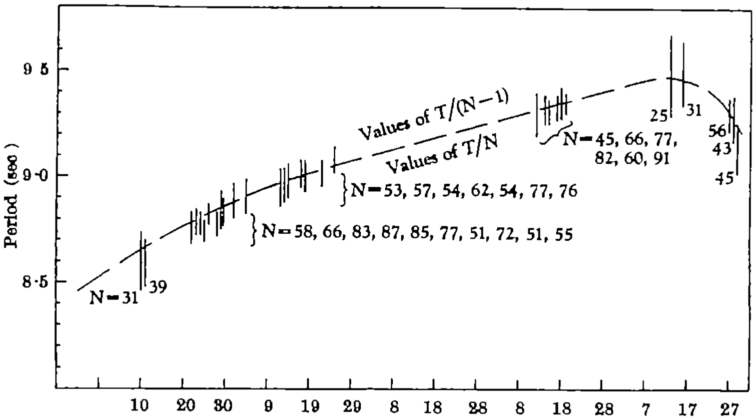

Fig. 1. Tumbling period of satellite $1958\delta 1$, estimated from observations of large numbers of flashes

In constructing Fig. 1, I have used only published observations[1,2] of large numbers of flashes. Each result gives an initial range of uncertainty as drawn between T/N and $T/(N-1)$, where T is the interval containing $(N+1)$ flashes.

The expression for the full rotation period:

$$P = 2T/(N - \theta/180)$$

gives consistent results, where θ is the angle of movement of the line of sight during an observation. The broken curve in Fig. 1 contains what appear to be essential features of the variation. Apart from timing errors, the true curve must pass through the tie-line joining T/N to $T/(N-1)$ for each observation, at a position depending on the value of θ, and therefore closer to $T/(N-1)$ when θ is large.

Any southern hemisphere observations (near apogee) during May or June 1958 would be a valuable check on the form of the early variation.

If it is accepted that a real change took place, at least in November, there follows the problem of finding an explanation. The idea of a 'cross-wind' introduces a non-symmetry of the correct kind, but I agree it should be stated relative to the satellite, and so represent the combined effect of rotation of the atmosphere and any westerly flow greater than the angular velocity of the Earth.

It seems necessary to seek an additional combination of deviations from, and extreme variations within, the ideal model used by P. Notni and H Oleak in their very thorough analysis.

During an interval when the change in angle B is small, the braking moment D_B is controlled by ρ, the air density at perigee. ρ can be calculated from the height of perigee[3], the air density at that height[4], and the deviation from the mean experienced by this satellite[5].

From August until the end of October 1958, the increase of ρ was small, and, apart from the 28-day period of solar disturbances, regular. During this period, the braking moment appears to have been constant. In November, ρ increased at a greatly increasing rate, while my Fig. 1 represents an increasing acceleration of tumbling. The data are not accurate enough to prove that the increase of acceleration is proportional to the increase of air density, but an explanation of the changes can be advanced on this assumption.

This requires proof first of a mechanism to convert most of the air friction to accelerating torque, and second, a main braking force independent of the air density.

The acceleration might arise from large non-symmetries of shape and weight distribution in the rocket body, and a true windmill effect

A precise evaluation of the contribution of magnetic damping may prove to be significant. For the case of a small rapidly rotating spherical satellite, Davis, Whipple and Zirker[6] found that the effect of air friction should be "several orders of magnitude less" than the expected damping of spin by the Earth's magnetic field. For $1958\delta 1$, there are factors of 500 in the rate of spin, and perhaps 10 in the ratio of axial length to diameter.

Note added in proof. I have not yet been able to study the discussion of magnetic retardation by Notni and Oleak in their ref. 6.

HD 101065—a G0 Star with High Metal Content

On April 26, 1960, in the course of a spectroscopic survey of stars with large proper motions, a spectrum of the eighth magnitude star *HD* 101065 was observed with the Zeiss spectrograph at the Newtonian focus of the 74-in. telescope at Mount Stromlo Observatory. This star, classified as a *B*5 star in the Henry Draper Catalogue, proved to be a much cooler star with a peculiar spectrum of unknown type. The spectral type of this star as estimated from the continuum, and later confirmed by three-colour photometry undertaken at my request by Mr. J. B. Whiteoak, is *K*0. The spectrum, however, shows strong hydrogen lines corresponding to class *F*8 or *G*0. The assumption that this star may have a composite spectrum could not be substantiated by the appearance of the spectrum in the violet region since the strength of all Balmer lines uniformly corresponds to that of a *G*0 star. The constant radial velocity of + 2·3 ± 1·0 km./sec. (based on three plates) and the six-colour photometry described here also suggest that the star *HD* 101065 is not a spectroscopic binary.

In view of the fact that no explanation could be found for the discrepancy between the spectral type determined from the continuum and from hydrogen lines (besides the obvious fact that the star in question has a peculiar spectrum) at my request this star was recently observed photoelectrically by Dr. G. E. Kron in six colours (private communication). The results of these observations are shown in Table 1 together with similar data for *HD* 19373—a normal main sequence *G*0 dwarf, ι Persei[1]—and *HD* 140283—an extreme *G*2 sub-dwarf (Stebbins, J., and Kron, G. E., private communication). Like the two other stars, *HD* 101065 is in all probability a dwarf, as the fairly high annual proper motion of 0·054″ and the six-colour photometry suggest. All three stars agree well in three colours, blue, green and red, and therefore should have essentially the same effective temperature not differing much from that of the Sun. If the difference in the infra-red is interpreted as a temperature effect the star *HD* 101065 should be the hottest and the sub-dwarf *HD* 140283 the coolest, but the difference should not be large. The three stars differ, however, considerably in their violet and ultra-violet colours. The sub-dwarf *HD* 140283, which according to L. H. Aller and J. L. Greenstein[2] and B. Baschek[3] contains only a negligible amount of metals in its atmosphere, possibly only 1/200 of the amount of metals in normal main sequence dwarfs, is the bluest, while the star *HD* 101065 is the reddest. The differences in the violet and ultra-violet are due to the differences in the degree of blanketing, that is, to the differences in the abundance of metals. The star *HD* 101065 should therefore have a much higher abundance of metal in its atmosphere than main sequence dwarfs. This is also suggested by the appearance of its spectrum, which contains about 500 lines, mostly unidentified, in the range λλ3922–4528 Å. on plates with a dispersion of 36 Å./mm. at Hγ, taken with the three-prism spectrograph at the Cassegrain focus of the 30-in. Reynolds telescope.

Table 1

Colour	*U*	*V*	*B*	*G*	*R*	*I*
λ in Å. / Star	3530	4220	4880	5700	7190	10,300
HD 140283	−0·52	−0·27	−0·04	−0·01	+0·03	+0·07
HD 19373	−0·16	−0·12	−0·03	−0·02	+0·05	+0·13
HD 101065	+0·08	+0·06	−0·04	−0·02	+0·07	+0·20

The high abundance of metals is also suggested by the appearance of the continuum. It can be expected that the contribution of metals to the continuous absorption coefficient would suppress the continuum below 4300 Å. or possibly up to λ4400 Å., and therefore a high content of metals would change the continuum in the sense that the star would appear to be of a later type. Since the spectral type estimated from the continuum and from the three-colour photometry is *K*0, while the temperature of the star indicates a spectral type *G*0, the abundance of metals which would cause such a marked change in the appearance of the spectrum must be very high indeed. It is hoped that the spectroscopic study which I have started will provide in the near future a precise figure for the abundance of metals. I expect that the abundance of metals will prove to be many times higher than that of normal main sequence stars.

The energy distribution based on photoelectric spectrophotometry recently secured at my request by Prof. L. H. Aller will be described in another paper now in preparation. This paper will also contain a detailed description of the spectrum; the main features, however, are briefly noted here. The ionized calcium lines *H* and *K*, which are very prominent in normal *F* and *G* dwarfs and even in sub-dwarfs, are faint and approximately equal in strength to hydrogen lines. Also, the absorption spectrum of iron is greatly suppressed and only three lines of iron (λλ4045, 4063, 4071 Å.) can be seen beyond any doubt; the line at λ4045 Å. is fairly strong. The lines of ionized strontium at λ4077 Å. and of barium at λ4554 Å. on the contrary are considerably strengthened in comparison with normal dwarfs. The spectrum shows about 500 lines between λλ3922 and 4528 Å., the majority of which have not yet been identified. Preliminary identifications seem to suggest that many lines should be attributed to rare earths. The spectrum does not show any *G* band, which could be interpreted as an indication that the abundance of carbon is low.

The high abundance of barium and strontium—two elements with the magic number of neutrons in their nuclei—as well as the high abundance of rare earths indicate that the star *HD* 101065 is in an advanced stage of stellar evolution. The star apparently passed through a stage of evolution in which heavy elements were built up by slow neutrons. It presents the same evolutionary problems as *S* stars, complicated in addition by the fact that in all probability it is a dwarf.

I wish to thank Dr. G. E. Kron, who at my request observed the star *HD* 101065 in six colours in spite of the fact that this meant a loss of valuable observing time during his short stay on Mount Stromlo, J. Stebbins and Dr. G. E. Kron for their permission to use unpublished data on *HD* 140283, and Mr. J. B. Whiteoak for securing the *UBV* photometry of *HD* 101065 at a time when this could not be done by me.

RADIOPHYSICS

The Total Electron Content of the Ionosphere during the Magnetic Disturbance of November 12–13, 1960

MEASUREMENTS of the total electron content of the ionosphere by observation of the differential Faraday fading of lunar radio echoes on two closely spaced frequencies were first made by Evans[1]. Use of a transit aerial limited observations to 1 hr. per day and permitted only the mean diurnal variation of the total electron content (n_t) to be obtained. Similar measurements are now being made with equipment mounted on the 250-ft. Jodrell Bank radio telescope; this allows up to 16 hr. continuous observation a day and gives reliable information on short-term and day-to-day variations in n_t. The frequencies used are 100·60 and 99·40 Mc./s.

The present communication presents some results obtained during a magnetic disturbance during November 12–14, 1960. The sudden commencement preceding the main phase of the disturbance occurred between 12.00 and 15.00 hr. U.T. on November 12, and the most intense phase of the disturbance ($K \geqslant 7$) was between 18.00 hr. on November 12 and 15.00 hr. on November 13. Curves of n_t vs. time for each of the days November 11–14 are shown in Fig. 1 (full line). The periods covered are those when the Moon was at a high enough elevation to permit useful observations. The curves have been corrected to local mean time at the sub-ionospheric point, and the mean sub-ionospheric latitude is 50·0° N. Also shown in Fig. 1 are hourly values of the maximum electron density N_m (points) derived from f_oF2 values for Slough (51·5° N. geographic, 54·3° N. geomagnetic) and 3-hourly K indices for the Hartland Magnetic Observatory.

K was low throughout the observational periods on November 11 and 12, and the n_t curves for these two days are normal. The disturbance began shortly after moonset on November 12, and the n_t curve for November 13 covers a large part of the most intense phase of the disturbance. n_t is lower than normal during the pre-sunrise period, and also shows an abnormally low rate of increase after sunrise, so that its midday value is less than one-third of that on the two preceding days. N_m is unmeasurable at Slough from 19.00 on November 12 until 03.00 on November 13, and is abnormally low throughout November 13. Both n_t and N_m are very low in the pre-sunrise hours of November 14 and both have returned to their normal values by midday on this day. Aurora was visible almost overhead at Jodrell Bank shortly before moonrise on November 13, but had retreated to the northern horizon before observations began. Visual observations of auroræ in the British Isles for the night of November 12–13 (Paton, J., private communication) show that it is unlikely that an aurora was present in the line of sight to the Moon at any subsequent time.

Table 1. BEHAVIOUR OF CERTAIN PARAMETERS AT SELECTED TIME DURING NOVEMBER 11–14, 1960

	Nov. 11	Nov. 12	Nov. 13	Nov. 14
n_t at 05.00 L.M.T.* (electrons/cm.^{2} × 10^{-12})	7·6 ± 1·3	10·9 ± 1·3	2·8 ± 2·1	0·8 ± 0·5
n_t at 10.00 L.M.T. (electrons/cm.^{2} × 10^{-12})	33·8 ± 1·7	35·4 ± 1·7	9·6 ± 2·9	30·2 ± 1·4
dn_t/dt from 07.00 to 10.00 L.M.T. (electrons/cm.^{2}/hr. × 10^{-12})	8·3	8·0	1·9	8·5
n_t/N_m at 05.00 L.M.T. (km.)	450 ± 80	570 ± 70	500 ± 300	200 ± 120
n_t/N_m at 10.00 L.M.T.	200 ± 10	200 ± 10	> 640	220 ± 10

* Local mean time.

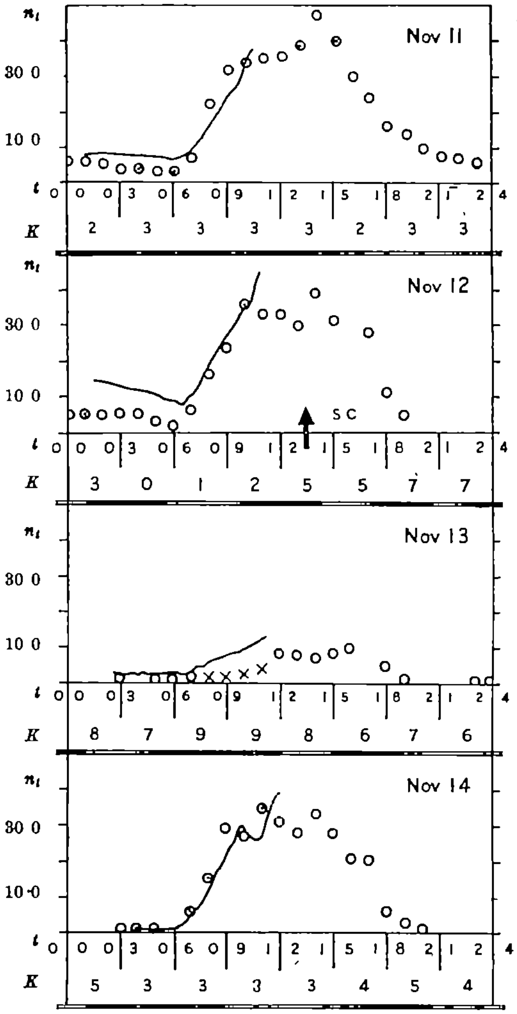

Fig. 1. Total electron content (n_t, full line) and Slough maximum electron density (N_m points) vs. time for each day during November 11–14, 1960. Also shown are Hartland K indices (K) and the approximate time of the sudden commencement on November 12 (S.C.). Upper limits are indicated as ×. Units: n_t, electrons/cm.^{2} column × 10^{-12}; N_m, electrons/cm.^{3} × 10^{-6}; t, hr.

Some relevant parameters for each of the four days are shown in Table 1. Listed here are n_t at 05.00 and 10.00 hr.; the mean rate of increase, dn_t/dt, between 07.00 and 10.00 hr.; and the equivalent column height, n_t/N_m, at 05.00 and 10.00 hr. The error in n_t is proportional to the error of measurement of the total number of Faraday rotations. This latter error is normally ± ½ rotation, and the corresponding errors in n_t are listed in Table 1. The errors shown for November 13 are rather larger than normal. This is partly because the Faraday fading on this day was slow and erratic throughout, and also because the record was partially obscured by interference for about an hour just before dawn.

The pre-dawn values of n_t are very low on both November 14 and 13; since magnetic activity was much lower at this period on November 14 than 13, the low value on the former date can probably be attributed to normal night-time decay following a low noon maximum on November 13. The low value of dn_t/dt after dawn on November 13 suggests that one of the effects of the disturbance may be either an increased rate of recombination or a decreased rate of production of electrons in the lower levels of the ionosphere, where most of the ionization originates. The equivalent column heights at 05.00 hr. lie in the normal range on November 13 and November 14, but this parameter appears to be abnormally high at 10.00 hr. on November 13.

Several workers have measured n_t during magnetically disturbed periods by observations of transmissions of satellites. Hame and Stuart[2] report decreases in n_t at two periods of high magnetic activity near the vernal equinox. Ross[3] finds an inverse correlation between n_t and K_p, the correlation being good in the summer but poor in the winter. Garriott[4] finds normal values of n_t and abnormally high equivalent column heights on disturbed days, the observations applying mainly to the winter half of the year.

These results are not necessarily inconsistent with the present ones, since all the previous observations were made at appreciably lower geomagnetic latitudes than apply here. Maeda and Sato[5] have shown that, at high latitudes, ionospheric disturbances are mainly 'negative' in type (f_0F2 decreases) at all times of the year, while in medium latitudes disturbances are predominantly negative in summer, but may be either positive or negative in winter. The importance of the observations described in this communication is to show that, at least on the present occasion, the reduction in N_m was accompanied by a proportional reduction in n_t. Thus there appears to have been a scaling down of the whole ionosphere rather than a vertical redistribution of ionization within it.

I wish to thank Sir Bernard Lovell for the use of the facilities of the Nuffield Radio Astronomy Laboratories and Dr. J. H. Thomson for valuable guidance. Thanks are also due to the Director of the Radio Research Station (Department of Scientific and Industrial Research), Slough, and the Superintendent of the Magnetic Department, Royal Greenwich Observatory, for permission to quote pre-publication values of f_0F2 and K indices respectively. This work was carried out under U.S. Air Force Contract No. *AF*61(052)–172.

PHYSICS

Optical Demonstration of Bragg's Law

A simple and rather striking demonstration of Bragg's Law can be given by making use of Lippmann's method for producing colour photographs[1]. In this method a photographic plate with an extremely fine-grained emulsion is placed with its sensitive layer on a mercury surface. It is then exposed from above, through the glass plate, to monochromatic light, for example from a sodium arc lamp. Due to reflexion at the mercury surface, standing light waves are produced in the sensitive layer, which, after development, give rise to parallel equidistant layers of photolytic silver, with a spacing equal to half the wave-length of sodium light.

Such a plate, of dimensions, for example, 3 cm. × 3 cm. (prepared in this Laboratory by B. Phielix, using, with some modification, a method described by H. Lehmann[2]), is fixed on a revolving holder, and inserted in an ordinary spherical glass flask as used in chemical experiments (diameter about 10 cm.). The flask is filled with benzene, to prevent reflexion at the outer surface of the emulsion layer. If now a parallel beam of white light, after passing through the solution, is reflected by the Lippmann plate, the latter acts as an 'interference mirror', and reflects a coloured beam, the colour changing with the angle of incidence. The reflected beam, when falling on a transparent screen, is of sufficient strength to be visible in a lecture room. In the experiment as I have performed it, the colour changes from yellow at a glancing angle θ in the neighbourhood of 90° to violet at θ about 45°.

The arrangement may serve to illustrate the influence of a slight change in spacing on the reflected wave-length. By breathing on the sensitive layer, a slight swelling of the gelatine takes place, which produces a considerable change in colour, from yellow to red for θ close to 90°, whereas for $\theta \sim 45°$ the colour of the reflected beam changes only from violet to blue. Thus also the different sensitivity of 'high-angle' and 'low-angle' reflexions for a slight change in spacing can be illustrated.

I do not know whether this 'application' of Lippmann's plates has already been described elsewhere. In a most interesting paper on "The Crystal Structure of *Tipula* Iridescent Virus as determined by Bragg-Reflection of Visible Light"[3], A. Klug, (the late) Rosalind E. Franklin and S. P. F. Humphreys-Owen analysed a crystal with lattice spacings so large that these could be measured by reflexion of visible light. Dr. Klug told me that cells containing these virus crystals had been used to demonstrate Bragg's law optically. This suggested to me that the above demonstration might be of some interest.

Acceleration of Deuterons in a Synchrotron

Because of the theoretical interest in the study of the collisions between nucleons, all the large heavy-particle synchrotrons at present operating have been designed to accelerate protons[1]. In many of these machines, however, the frequency of the accelerating voltage can be pre-set to follow any suitable law of variation with magnetic field. There is nothing then to prevent the acceleration to an appropriate energy of particles with an e/m different from that of the proton providing that they can be injected.

In the Birmingham proton synchrotron[2] the radio-frequency law was originally obtained by a rotating condenser which varied the capacity in an oscillator circuit[3]. This system has now been successfully replaced by an analogue computer and a function generator, driven by a signal proportional to the rate of change of magnetic field, the output signal controlling a variable capacitance diode in an oscillator circuit. This allows considerably greater flexibility. The low injection energy and small aperture of the Birmingham machine impose severe limits on the permissible errors of the radio-frequency at injection. As a result, the system requires a signal to noise (and drift) ratio of $10^5:1$, and this has been achieved. It has been found possible to accelerate deuterons readily with this installation.

Deuterium gas was supplied to the radio-frequency ion source of the synchrotron injector. With the same injection energy as for protons (460 keV.) a beam was found to enter the synchrotron vacuum system and to circulate before acceleration at a magnetic field of $\sqrt{2}$ times the value for protons. This beam was carried to full energy (estimated from the magnetic field to be 642 ± 12 MeV. for mass 2) by suitable adjustment of the radio-frequency function generator and was found to circulate at maximum field with a frequency 0·76 times that for protons. The beam was extracted from the synchrotron by the method normally used for protons[4] and was found to have an intensity of 10^8 particles per pulse over an area of 12 cm.^{2} at a distance of 16 m. from the extractor. The range of the beam in copper was measured to be 167 ± 3 gm. cm.$^{-2}$ which, allowing for 7-MeV. energy-loss in polythene and air in the beam path, corresponds to an energy of 640 ± 5 MeV., confirming that the particles accelerated were deuterons. No beam was accelerated when hydrogen gas was fed to the ion source with the radio-frequency generator set for deuterons.

The identity of the accelerated particles was also confirmed in a preliminary experiment to measure the differential cross-section for the elastic scattering of deuterons by protons. Coincidences between scattered deuterons and recoil protons from a hydrogenous target were recorded at the correct correlation angle; when the counter telescopes were moved off this angle the counting-rate dropped to 20 per cent of that previously obtained. It is hoped to continue these observations and to extend them to a study of the deuteron–deuteron interaction at the available energy.

The new radio-frequency installation was developed from a system proposed by W. Boyd and his team at the National Institute for Research in Nuclear Science, Harwell. We wish to acknowledge the valuable help we have received from them at all stages of the work. We are also indebted to D. A. Gray of the Institute for assistance in the problem of deriving signals from the rising magnetic field. Many members of the synchrotron group of this laboratory also contributed to this project, in particular K. R. Chapman, who made the necessary adjustments to the ion source, and the Counter Group, who made the range and scattering measurements.

The Quasi-Longitudinal Approximation to the Appleton–Hartree Equation

IF an electromagnetic wave passes through a medium containing free electrons, which may make collisions with heavy particles, in the presence of a uniform magnetic field, the refractive index and absorption coefficient of the medium are given by the Appleton–Hartree equation[1]:

$$n^2 = (\mu - i\chi)^2 =$$
$$1 - \frac{X}{1 - iZ - Y_T^2/2(1 - X - iZ) \pm [Y_T^4/4(1 - X - iZ)^2 + Y_L^2]^{1/2}} \qquad (1)$$

where μ = refractive index; χ = absorption coefficient; $X = f_0^2/f^2$; $Y_T = (f_H/f)\sin\theta$; $Y_L = (f_H/f)\cos\theta$; $Z = \nu/2\pi f$; f = frequency of wave; f_0 = plasma frequency; f_H = gyrofrequency; ν = frequency of collisions between electrons and neutral molecules; θ = angle between wave normal and magnetic field.

Because of the complicated nature of the above equation the quasi-longitudinal and quasi-transverse approximations, first discussed by Booker[2], are often used.

The quasi-longitudinal approximation holds when:

$$Y_T^4/4Y_L^2 \ll (1 - X)^2 + Z^2 \qquad (2)$$

It is generally quoted as:

$$n^2 = 1 - X/(1 - iZ \pm |Y_L|) \qquad (3)$$

Equation (3) means that the wave behaves very much as if it is being propagated along the direction of the magnetic field, since, for longitudinal propagation, equation (1) reduces to:

$$n^2 = 1 - X/(1 - iZ \pm Y) \qquad (4)$$

However, equation (3) is incorrect, as can easily be seen by considering the denominator of the second term of equation (1):

$$1 - iZ - Y_T^2/2(1 - X - iZ) \pm$$
$$[Y_T^4/4(1 - X - iZ)^2 + Y_L^2]^{\frac{1}{2}}$$

When the inequality (2) holds, this becomes:

$$1 - iZ - Y_T^2/2(1 - X - iZ) \pm |Y_L|$$

and $Y_T^2/2(1 - X - iZ)$ is not necessarily negligible compared with Y_L. In fact, if we assume the usual numerical condition that the inequality (2) is satisfied if the larger quantity is nine times the smaller, then $|Y_T^2/2(1 - X - iZ)|$ may be as large as $\frac{1}{3}Y_L$. The correct approximation is thus:

$$n^2 = 1 - \frac{X}{1 - iZ - Y_T^2/2(1 - X - iZ) \pm Y_L} \qquad (5)$$

and the wave does not behave as if it were propagated along the direction of the magnetic field. It will only behave thus when the term $Y_T^2/2(1 - X - iZ)$ can be neglected, that is, when:

$$Y_T^2/2Y_L \ll |(1 - X) - iZ| \qquad (6)$$

Outside these limits, but where inequality (2) still holds, equation (5) should be used. A similar correction should also be made to the expressions for the polarization.

I am grateful to Prof. J. A. Gledhill for some helpful discussion.

MINERALOGY

Kilchoanite, a Polymorph of Rankinite

THE compound $9CaO6SiO_2H_2O$ was originally synthesized and described by Roy[1,2], who called it phase *Z*. Revised data on its properties have been given by Roy, Gard, Nicol and Taylor[3], who showed that, when hydrothermally synthesized at 715° C. and with a pressure of 1,100 bars, its composition was $3CaO2SiO_2$ and that it became inverted to rankinite on heating between 954° C. and 1,090° C.

A mineral corresponding to phase *Z* has been found in limestones thermally metamorphosed by gabbro at Ardnamurchan, Scotland, and Carlingford, Eire. It has been named kilchoanite after the village in Ardnamurchan near where it was first found.

It has the following properties: colourless, slightly turbid due to minute inclusions and no visible cleavage, α 1·647, γ 1·650, $\gamma - \alpha$ 0·003, $+ 2V$ 60°, dispersion distinct $r > v$, density 2·992. In thin section the interference colours are commonly weak ultra-blue and ultra-brown.

Kilchoanite has always been found as a replacement of rankinite and no crystal form has been observed. Single crystal X-ray data indicate that it is orthorhombic with *a* 11·42 Å., *b* 5·09 Å., *c* 21·95 Å. (all ± 0·05 Å.). The Laue group is *mmm* and the probable space group *I mam* or *I ma*2. X-ray powder data, given in Table 1, agree with those of Roy[2] for the phase *Z* apart from discrepancies which could be due to impurities in the latter.

Separation of kilchoanite for analysis was difficult owing to the complexity of the mineral assemblages with which it is associated and because of its irregular distribution. A rock containing no rankinite was eventually used to prepare a sample in which spurrite was the only impurity. Having established that kilchoanite contained no carbon dioxide, this sample was analysed. On the assumption that all the carbon dioxide was in the contaminating spurrite, this analysis, together with the cell dimensions and the determined density, gave the calculated cell contents as:

$$(\mathrm{Ca}_{23\cdot47}\mathrm{Mn}_{0\cdot03}\mathrm{Fe^{III}}_{0\cdot05})_{23\cdot55}(\mathrm{Si}_{15\cdot71}\mathrm{Al}_{0\cdot35})_{16\cdot06}(\mathrm{O}_{55\cdot53}\mathrm{OH}_{0\cdot47})_{56\cdot00}$$

This value is in close agreement with $8(Ca_3Si_2O_7)$ and confirms that kilchoanite corresponds to the phase *Z* and is a polymorph of rankinite. Further confirmation is found in that on heating at 1,000° C. for 10 hr. a single crystal of kilchoanite became inverted to a polycrystalline aggregate of rankinite.

The metamorphic assemblages from which kilchoanite is developed consist essentially of:

rankinite—spurrite—melilite
rankinite—wollastonite—melilite

These give way to assemblages such as:

rankinite → kilchoanite — spurrite → tilleyite — melilite — cuspidine
kilchoanite — tilleyite — melilite — cuspidine
kilchoanite — spurrite — grossular — idocrase — cuspidine
kilchoanite — wollastonite — grossular — idocrase

It is suggested that kilchoanite does not form in normal prograde metamorphism as under conditions of relatively high carbon dioxide pressure the reaction spurrite + wollastonite → rankinite + carbon dioxide, is above the stability limit of kilchoanite. If, however, the rock has been decarbonated, a later retrograde phase or repeated thermal metamorphism under a low carbon dioxide pressure may convert the rankinite to kilchoanite at lower temperatures in the presence of water.

Further work on this mineral and these rocks is in progress and will be reported in detail later.

CRYSTALLOGRAPHY

Etch Patterns on Cadmium Crystals grown from Vapour

SERVI[1] showed complex spirals on the basal plane of cleaved zinc crystals after etching, and spiral terraced etch pits have been obtained on zinc crystals[2] grown from vapour using 'Superoxol' etch. Presented here are two types of etch figures obtained on 99·9 per cent cadmium crystals grown from vapour. Of several etching reagents that had been tried the most suitable one was a saturated solution of picric acid in acetone and a normal time of 2 min. was decided on. For longer periods of etching the solution acted as polishing agent.

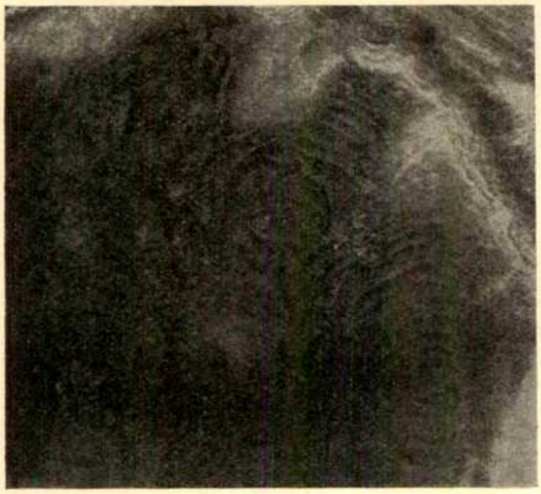

Fig. 1

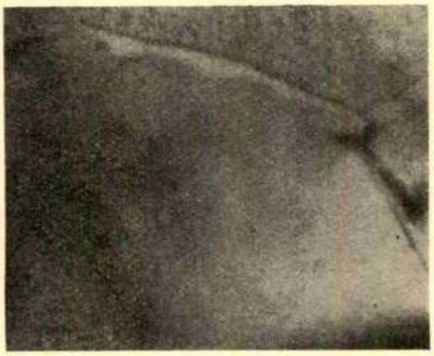

Fig. 2

Several complex spirals were observed on the basal planes of some of the crystals after etching (Fig. 1). The hexagonal symmetry of the basal plane is clearly indicated in these spirals. This suggests that crystal symmetry is a factor in etch spiral formation. As the spiral moves outwards it breaks up into terraces, and a sort of interlacing occurs. It is interesting to note that the spirals break and make along crystallographic directions. In some cases etch patterns closely resembling hexagonal spirals with the dislocation line emerging at the centre were observed (Fig. 2). It is evident that these etch pits are formed at the sites of dislocations.

GEOLOGY

Palæoecology of Carboniferous Peat Bogs

THE microscopic examination of coals can provide valuable information on their mode of formation. The works of Teichmüller[1] and Thomson[2] on the Rhineland brown coal are notable examples. Apart from the investigations of Kremp[3] and Smith[4], little of the published work on the possible origin of the different petrographic types of coal takes account of the evidence provided by the plant spores in coals of Carboniferous age.

Recently, a systematic study of the petrology and palynology of British bituminous coals from the Lower and Middle Coal Measures of the East Pennine coalfield has yielded results which are not only of theoretical importance, but also provide information which will permit the more effective use of spores in the correlation of coal seams. These results are being prepared for publication.

Broadly speaking, each of the more important petrographic coal-types possesses a distinctive assemblage of miospores (and probably megaspores). Four main types of assemblage have been recognized, associated respectively with predominantly bright, interbanded, and the two distinct petrographic types of dull, coal. These assemblages are related in the order in which they succeed one another in seam profiles. A full sequence is found only in seams containing dull coal characterized by the petrographic constituents micrinite (massive) and exinite, the latter largely comprising the exines of a single spore *Densosporites sphaerotriangularis* Kos. A sequence may be repeated more than once within a seam profile.

It is possible to recognize, within the profiles, horizons with distinctive petrological and palynological features which include allochthonous elements. These horizons probably mark the flooding of the bog surface and their occurrence may modify the development of a sequence.

From what is known of the botanical affinities of the spores, it is possible to visualize something of the nature of the plant succession corresponding to the sequence of miospore assemblages. The conditions under which peat formed may be inferred from the nature and possible origin of the petrographic constituents associated with the different assemblages of spores.

Any hypothesis as to the conditions under which peat was formed in the Carboniferous must take account of the evidence provided by work on the frequency and stratigraphic ranges of spores found in the seams in all the major British coalfields. These have demonstrated an essentially identical pattern of distribution and abundance in the different coalfields. Also to be considered is the occurrence, over wide areas within a coalfield, of beds, often nearly constant in thickness, of dull coal containing massive micrinite and spores predominantly of one type. This petrographic type is known from coals of paralic and limnic origin, and is a conspicuous feature of the middle and upper portions of certain seams in the Lower and Middle Coal Measures in Britain.

With regard to the palynological evidence, it is thought unlikely that the quantitative and qualitative composition of the miospore assemblages from whole seams of coal deposited contemporaneously would show common features if depth of water cover or salinity had been the controlling factor determining the nature of the vegetation growing in the areas of peat deposition. Considering those features of the dull coal to which reference has been made, W. G. Chaloner (personal communication) suggested that the formation of peat of a distinctive type within certain Carboniferous bogs may have taken place under conditions similar to those which give rise to blanket bogs at the present time, and that the causative factor was more likely to be a climatic (for example, rainfall) fluctuation than simply one of water-level.

Such a mode of origin accords well with the observed facts. By analogy with present-day raised bogs, it seems reasonable to suggest that the vertical changes which took place as peat accumulated in these Carboniferous deposits may have been the result of the increase in acidity and the decrease in nutrients available for plant growth. On this view, therefore, the sequences which have been observed may mark the change from peat of eutrophic to that of oligotrophic type.

It is of interest that the study of the peat deposits of north-west Borneo by Andrews and Richards[5] suggests that these peats are of raised-bog type. The vegetation growing on these peats is arboreal and is reported to exhibit a concentric zonation. Profiles from the central parts of the deposit show a succession of peat types formed from the same plant communities that occur at the present time from the periphery to the centre. In this and other respects there is probably a close analogy with the structure observed in certain coals which originated in Carboniferous peat bogs.

The mode of peat formation, which it is suggested might account for the petro-palynological characteristics of certain Carboniferous coal seams, is different from that postulated by Teichmuller[6] for the brown coals of the Rhineland.

The possible climatic control of bog structure in the Carboniferous would explain features of the distribution and abundance of miospores in coal seams of the period.

This work is published by permission of the Director of Scientific Control of the National Coal Board.

CHEMISTRY

Polymers and the Theory of Numbers: Molecular Weight Distributions from Rheological Measurements

Recently, V. S. Nanda and R. K. Pathria have shown how certain problems from the theory of numbers may be applied to the theory of polymer degradation[1]. Their work appears to be one of the very few applications of the theory of numbers to physical or chemical problems. We wish to report a new application of another classical theorem of the theory of numbers to yet another problem in the field of polymer physical chemistry. By the use of this theorem, it appears to be possible to obtain the molecular weight distribution of a polymer sample from rheological measurements.

Rouse's equation[2] for the real part of the complex viscosity of a polymer solution may be written as:

$$\eta_1(\omega) = K \sum_{p=1}^{\infty} f(\omega/p^2) \qquad (1)$$

where η_1 is the real part of the complex viscosity, ω is the frequency and K is a frequency-independent parameter.

The function $f(\omega/p^2)$ is a type of Stieltjes transform of the molecular weight distribution function, $Z(M)$, defined as $MW(M)/\overline{Mw}$, where $W(M)$ is the weight fraction of polymer between molecular weights M and $M + dM$, and $\overline{Mw}$ is the weight-average molecular weight. In fact, $Z(M)$ is related to $f(\omega) \equiv f(\omega/1^2)$ by the relation:

$$Z(M) = \mathscr{S}\{(f(\omega)\} \qquad (2)$$

where $\mathscr{S}$ stands for inversion of the Stieltjes transform. Such an inversion may be obtained to any desired approximation through the use of the inversion formula of Hirschman and Widder[3]. In order to obtain $f(\omega)$ from equation (1), we use the classical number-theory theorem of Moebius[4] to obtain:

$$f(\omega) = K^{-1} \sum_{s=1}^{\infty} \frac{\mu_s}{s^2}\eta_1(\omega/s^2) \qquad (3)$$

where μ_s is the Moebius μ-function defined as equal to $+1$ if s is $+1$ or if s can be factorized into an even number of unlike primes and -1 if s can be factorized into an odd number of unlike primes, and zero for other values of s. Combining (2) and (3), we have:

$$Z(M) = \mathscr{S}\left\{K^{-1} \sum_{s=1}^{\infty} \frac{\mu_s}{s^2}\eta_1(\omega/s^2)\right\} \qquad (4)$$

Thus if $\eta_1(\omega)$ is known experimentally for any polymer, equation (4) gives an equation for directly obtaining the molecular weight distribution function. The potential usefulness of such a relation lies in the fact that it may present a far easier and more rapid method of experimentally determining the molecular weight distribution of a polymer than has heretofore been possible.

The BH_4^- Ion in the Lithium Borohydride Lattice

Price[1] reports an anomalous band at about 1,250 cm.$^{-1}$ in the paraffin-oil mull spectrum of lithium borohydride at room temperature. This band does not occur in the room-temperature spectra of sodium borohydride[2,3] and potassium borohydride[3] or in the low-temperature spectra of sodium borohydride[2,4] and potassium borohydride (Schutte, C J. H., unpublished results).

The crystal structure of lithium borohydride is orthorhombic (space-group V_h^{16}) with four molecules per unit cell[5].

V_h^{16} has the following sites[6]: $2C_i(4)$ and $C_s(4)$. A comparison of the site groups of the space group and the sub-groups of the ionic point group (T_d) shows that the BH_4^- ion is on site C_s. The local-symmetry group of the ion, constructed from the common elements of the site group and the space group, is C_s.

The symmetry of the perturbing crystal field acting on the tetrahedral BH_4^- is thus C_s. Under the action of a perturbing field of symmetry C_s the vibrational levels of the tetrahedral ion transform as follows :

$$\begin{tikzcd}[row sep=small]
T_d & C_s \\
A \arrow[r] & A' \\
 & A' \\
E \arrow[ur] \arrow[dr] & \\
 & A'' \\
 & A'' \\
F_2 \arrow[ur] \arrow[r] \arrow[dr] & A' \\
 & A'
\end{tikzcd}$$

that is, the degeneracy of all the levels is removed and all the levels are infra-red active (only the F_2 levels are infra-red active under T_d).

This means that all four tetrahedral fundamentals should be observable in the infra-red absorption spectrum, as well as all the overtones and combination bands In addition, all the degenerate bands should show fine structure caused by the removal of all the degeneracy by the perturbing crystal field.

The splitting of the degenerate bands would probably be obscured by the broadness of the bands at room temperature, but ν_1 and ν_2 should be observable. Unfortunately, the band due to the ν_1 vibration lies among ν_3 and its satellite bands (at about 2,300 cm.$^{-1}$) and could easily be obscured by these.

From the spectrum published by Price[1] it can be deduced that ν_2 should occur around 1,280 cm.$^{-1}$ (from the frequencies of ν_4 and $\nu_2 + \nu_4$).

The anomalous band reported by Price[1] at about 1,250 cm.$^{-1}$ in the spectrum of lithium borohydride can thus probably be assigned to the ν_2 vibration of the BH_4^- ion in the lithium borohydride lattice. This band is normally inactive in the infra-red, but occurs here because of the 'reduction' of the symmetry of the ion by the crystalline field, which is of the type C_s.

Isolation of D-Glycero-D-galacto-heptitol from the Wound Exudate of Avocado Trees

D-GLYCERO-D-GALACTO-HEPTITOL has been isolated from the semi-crystalline exudate of wounds in the bark of *Persea americana* Mill.

The crude material was a pale brown solid which did not reduce Fehling's solution, and gave evidence of only one major component on paper chromatograms. Two recrystallizations of this solid from aqueous methanol afforded a colourless product in the form of needles which had a melting-point of 183–185°, no depression on admixture with authentic perseitol.

A portion of the crude exudate was acetylated with pyridine and acetic anhydride to give a crystalline acetate, which after recrystallization from aqueous ethanol had a melting-point of 119–120·5°, no depression on admixture with authentic perseitol heptacetate. This derivative also had $[\alpha]_D^{22°} -14°$ (about 2·02 in chloroform); literature value[1] $[\alpha]_D^{16°} - 13·3°$ (chloroform).

A further portion of the crude material was treated with benzaldehyde and acid according to Hudson *et al.*[2]. From this reaction mixture a crystalline derivative was isolated, which after one recrystallization from pyridine–ethanol had a melting-point of 276–278° and $[\alpha]_D^{17°} -62°$ (about 1·95 in pyridine). Hudson *et al.*[2] give values of 277 ± 2° for the melting-point and $[\alpha]_D^{16°} -58·1°$ (about 0·9 in pyridine) for 1,3 : 5,7-di-O-benzylidene-D-glycero-D-galacto-heptitol.

From these results we have concluded that the chief constituent of *Persea americana* Mill wound exudate is D-glycero-D-galacto-heptitol (perseitol), a compound known to be present in the fruit[3] and leaves[4] of this tree.

Thanks are due to Drs. L. W. Klotz and G. A. Zentmyer of the Citrus Experiment Station, Riverside, California, who supplied the exudate described here.

Monosaccharide Sequence in *Pneumococcus* Type XIV Polysaccharide

PREVIOUS work[1] has established that in *Pneumococcus* type XIV polysaccharide there are two non-reducing end groups of D-galactopyranose, one D-galactopyranose residue linked 1 : 3, one D-glucose residue linked 1 : 4 and two 1 : 4 : 6-linked 2-acetamido 2-deoxy D-glucose residues for every six monosaccharide units. Although the majority of these linkages are β-, some α-D-galactose units may be present. The two major disaccharides left after treatment of the type XIV polysaccharide with *N* hydrochloric acid at 100° for 2½ hr. were 4-O-β-D-glucosyl 2-acetamido 2-deoxy D-glucose and 3-O-β-(2-acetamido 2-deoxy)-D-glucosyl D-galactose. Less drastic hydrolysis has enabled other disaccharides to be isolated and the structure of these is the subject of the present communication.

The polysaccharide (3·606 gm.) was hydrolysed with 2 *N* sulphuric acid (430 ml.) at 85–90° C. for 2½ hr. After neutralization with barium carbonate, the hydrolysate was passed through 'Amberlite *IR*' 120 (H+), which was eluted with water to yield neutral sugars (1·8 gm.) and with 2 *N* sulphuric acid to remove basic sugars (1·0 gm.). Fractionation of the neutral sugars on a charcoal–'Celite' column[2] gave a D-galactose–D-glucose mixture (about 1·4 gm.), N-acetylglucosamine (40 mgm.), disaccharides I and II (4 mgm.), III (11 mgm.), V (30 mgm.), VI (3 mgm.), trisaccharides IV and V (30 mgm.), as well as trisaccharide VI and another oligosaccharide (30 mgm.).

The basic sugars were selectively N-acetylated[3] and fractionated on a charcoal–'Celite' column[2] to yield a D-galactose–N-acetylglucosamine mixture (0·80 gm.), disaccharides IV (9 mgm.), V (20 mgm.), trisaccharides I (6 mgm.), II (3 mgm.), III (12 mgm.) and higher oligosaccharides (24 mgm.). Disaccharides and trisaccharides are numbered in order of elution from the charcoal–'Celite' column.

Acid hydrolysis of disaccharide III (1 mgm.) and paper chromatographic analysis of the products showed that III contained D-galactose and D-glucose. Reduction of III with sodium borohydride afforded a disaccharide alcohol the components of which were D-galactose and sorbitol. Hence III was a galactosylglucose. III showed on paper chromatograms R_{glucose} values of 0·33 in butanol/acetic acid/water (40 : 10 : 50), 0·45 in amyl alcohol/pyridine/water (1 : 1 : 1) and on paper ionophoretograms[4] an M_G value of 0·37 in borate buffer pH 10. In each case this behaviour was identical with that of lactose, and III is therefore 4-O-β-D-galactopyranosyl-D-glucose.

The mixture of disaccharides I and II was separated (R_{glucose} values 0·26 and 0·33 respectively) on paper chromatograms irrigated with an amyl alcohol/pyridine/water (1 : 1 : 1) mixture. Acid hydrolysis of II gave D-glucose and D-galactose. Disaccharide II alcohol contained glucose and dulcitol. Since D-galactose must therefore occupy the reducing position in the disaccharide and previous methylation data[1] had established only 3-substituted galactose units, disaccharide II must be 3-O-β-D-glucosyl D-galactose. Its high mobility (M_G 0·70) on borate ionophoresis[4] supports this contention. Disaccharide I contained only D-galactose. Hydrolysis of disaccharide I alcohol gave galactose and dulcitol. Its high mobility (M_G 0·82) on borate ionophoresis[4] supports the assignment of its structure as 3-O-D-galactosyl-D-galactose.

Similar structural investigations established that disaccharides V and IV were identical with 4-O-β-D-glucosyl-2-acetamido 2-deoxy D-glucose and 3-O-β-(2-acetamido 2-deoxy)-D-glucosyl-D-galactose, which had been encountered in previous work[1]. Since the small amounts of disaccharides isolated might have arisen via acid reversion, a control experiment was carried out in which a synthetic mixture of D-galactose, D-glucose, and N-acetyl D-glucosamine (3 : 1 : 2) was submitted to the identical conditions of acid hydrolysis, etc., used in the hydrolysis of the polysaccharide. Only one disaccharide was detected, and this corresponded to disaccharide VI.

Trisaccharide VI (R_{glucose} 0·20 in butanol/acetic acid/water; 0·28 in amyl alcohol/pyridine/water; M_G 0·10 in borate buffer) contained galactose, glucose and N-acetylglucosamine. Partial acid hydrolysis gave as well as these sugars the disaccharides III and V. Sodium borohydride reduction of trisaccharide VI and subsequent partial acid hydrolysis gave galactose, glucose and disaccharide III as the only reducing sugars. Hence trisaccharide VI is probably O-β-D-galactosyl-(1→4)-O-β-D-glucosyl-(1→4) D-(2-acetamido 2-deoxy)-glucose. Trisaccharides IV and V also contained galactose, glucose and N-acetylglucosamine as their component monosaccharides.

Although the fine details of the structure of type XIV polysaccharide must still await the characterization of other trisaccharides and higher oligosaccharides, the following points are significant with respect to the cross-reactivity of anti-type XIV *Pneumococcus* sera and various polysaccharides. Both human blood group A substance[5] and type XIV polysaccharide contain the disaccharide 3-O-β-(2-acetamido 2-deoxy)-D-glucosyl-D-galactose. Anti-type XIV sera do not react with intact A substance, but do so after treatment with acetic acid. Intact human Le^a blood group substance probably cross-reacts with anti-type XIV sera solely because of the presence of non-reducing end groups of D-galactose, since Watkins and Morgan[6] have concluded from inhibition studies that such terminal β-D-galactosyl groups are attached to the 3 position of neighbouring N-acetylglucosamine residues. No evidence has been found for the presence of 4-O-β-D-galactopyranosyl N-acetylglucosamine, which has been found[7] in pig group A substance and is believed by Schiffman, Howe and Kabat[8] to be responsible for cross-reactivity with anti-type XIV sera. The detection by us of 3-O-D-galactosyl D-galactose in type XIV polysaccharide is consistent with the presence of this disaccharide in lung galactan and other polysaccharides containing galactose which cross-react[9–11] with anti-type XIV sera. However, the cross-reaction of guar gum[12] with anti-type XIV sera appears to be due to the non-reducing α-D-galactose terminal units in this polysaccharide.

We are indebted to Prof. M. Heidelberger for his interest in this work and the gift of type XIV polysaccharide. One of us (M. C. K.) is grateful to the Colonial Products Research Council for the award of a research scholarship.

BIOCHEMISTRY

Role of Tocopherol, Selenium and Anti-oxidants in the Rat

THE view that α-tocopherol functions solely as a lipid anti-oxidant has long been implicit in the conclusions of many workers (Dam[1] has given a useful summary) and has again been most recently elaborated in the work of Zalkin and Tappel[2]. Other workers, however, have postulated a more specific role for tocopherol in animal tissues. We have already shown[3,4] that α-tocopherol and selenium both control ubiquinone-levels in the rat, and wish briefly to report here some work that provides strong evidence for a specific biochemical function of tocopherol, distinct from that of other lipid anti-oxidants.

Groups of six weanling female rats were reared for 10–12 weeks on a vitamin E-deficient diet. Some groups received throughout this period dietary supplements of 0·01 per cent *dl*-α-tocopheryl acetate, or 0·1 p.p.m. of selenium (as selenite) or 0·10 per cent of 'Santoquin' (1,2-dihydro-6-ethoxy-2,2,4-trimethylquinoline). Other groups were given 80 mgm. of 'Santoquin' or 10 mgm. of α-tocopheryl acetate 48 hr. before all groups were killed. Tissues were analysed for ubiquinone and tocopherol by previously described methods[5]. Table 1 shows that, whereas tocopherol and selenium (which usually increased tissue tocopherol-levels) markedly increased ubiquinone in heart and liver, 'Santoquin' was inactive. Similar effects were found in other tissues.

Table 1. Effect of α-Tocopherol (α-Toc.), Selenium and 'Santoquin' on Ubiquinone (UQ) in Rat Tissues

Group and treatment	Heart UQ (μgm./gm.)	Heart α-Toc. (μgm./gm.)	Liver UQ (μgm./gm.)	Liver α-Toc. (μgm./gm.)
Control	144	1·8	62	0·7
+ 0·01 per cent α-Toc.	170	44·5	92	41·9
+ 10 mgm. α-Toc. dose	165	12·6	83	30·0
+ 0·10 per cent 'Santoquin'	128	1·4	68	6·5
+ 80 mgm. 'Santoquin' dose	151	1·3	65	6·6
+ 0·1 p.p.m. selenium	195	8·2	93	6·8

Table 2 illustrates another experiment. Four groups of 8 female rats were reared on the deficient diet to 4 months of age. One group received a dietary supplement of 0·05 per cent DPPD (N,N′-diphenyl-*p*-phenylenediamine), two other groups dietary 'Santoquin' (at either 0·015 or 0·10 per cent). The animals were killed and livers analysed for ubiquinone and vitamin A. At the same time, *in vitro* peroxide production was measured on three individual livers from each group of the thiobarbituric acid reaction[6], after incubating homogenates for 15 min. at 37°. Optical densities were recorded directly. Both N,N′-diphenyl-*p*-phenylenediamine and 'Santoquin' effectively protected vitamin A (increased liver storage) and both significantly prevented *in vitro* peroxidation in liver. Neither substance significantly increased ubiquinone in heart or liver.

Table 2. The Effect of 'Santoquin' and DPPD on Ubiquinone (UQ) and Vitamin A in the Rat, and their Protective Action on Peroxidation

Group and treatment	Tissue	UQ (μgm./gm.)	Vitamin A (I.U./gm.)	Liver peroxidation* (E at 520 mμ)
Control	heart	208		
	liver	106	116	14
0·05 per cent DPPD	heart	186		
	liver	96	178	8*
0·10 per cent 'Santoquin'	heart	227		
	liver	114	146	11*

*Significantly different from controls ($P = 0·01$).

Dietary selenium did not prevent lipid peroxidation in the rat, whether animals were fed casein-based vitamin E-deficient diets or 'necrogenic' vitamin E/selenium-deficient diets. In a typical experiment, groups of 16 weanling rats were fed a 'necrogenic' bakers' yeast diet, one group being supplemented with 0·05 p.p.m., another with 0·5 p.p.m. of selenium (as sodium selenite), and another with 0·01 per cent *dl*-α-tocopheryl acetate. Three rats in the control group died of liver necrosis at the twenty-third, twenty-sixth and twenty-ninth day; selenium or tocopherol fully protected the other animals. Livers were examined at 20 and 26 days for *in vivo* and *in vitro* peroxidation and the results show (Table 3) that, in contrast to tocopherol, selenium had no significant protective effect on peroxide formation in rat liver.

Table 3. Effect of Selenium on Lipid Peroxidation of Rat Liver

Group and treatment	Liver peroxides (E at 520 mμ) *in vivo*	*in vitro*
Control	6 (4–6)	9 (8–11)*
+ 0·05 p.p.m. selenium	6 (4–8)	10 (8–14)*
+ 0·5 p.p.m. selenium	6 (4–6)	11 (8–11)*
+ 0·01 per cent α-tocopheryl acetate	4, 4, 4	7, 6, 7†

* Mean and range of 7 determinations. † Individual determinations.

These experiments suggest that the mechanism(s) by which α-tocopherol and selenium increase ubiquinone in the rat can be divorced from the general anti-oxidant function of the former substance. Under conditions in which two powerful anti-oxidants have been demonstrated to carry out their function, they were unable to influence ubiquinone; selenium, on the other hand, had no demonstrable anti-oxidant properties, but a tocopherol-like effect on ubiquinone. This work will be reported in full elsewhere.

Role of Selenium in Relation to Ubiquinone in the Rat

In a preliminary communication[1] and in more detailed work[2], we have shown that α-tocopherol and selenium independently control ubiquinone-levels in the rat, and a similar relation between tocopherol and ubiquinone has been found in the rabbit[3]. We have proposed a theory of vitamin E function which can be briefly summarized as follows. Although animal species vary considerably in their requirements for tocopherol, an even more important variation exists in individual tissue requirements for the vitamin, and in the rates at which tissues become depleted in vitamin E deficiency. Thus, in the rat, uterus normally contains a relatively high concentration of tocopherol and is rapidly depleted, whereas, in the rabbit, skeletal muscle is the tissue most readily depleted. In both these tissues, diminished ubiquinone-levels are the result and may be causally related to the specific syndromes of vitamin E-deficiency, fœtal resorption in the rat and muscular dystrophy in the rabbit. The remarkable species differences in vitamin E deficiency are, according to this hypothesis, a reflexion of local tissue tocopherol deficiencies.

We have now studied the implications of such a hypothesis with respect to the role of selenium. Selenium prevents or cures some symptoms of vitamin

Table 1. EFFECT OF ORALLY ADMINISTERED SELENIUM AND α-TOCOPHEROL (α-TOC.) ON UBIQUINONE (UQ) IN FEMALE RATS

Control	144	62	56	13
+ 0·1 p.p.m. selenium	195	98	66	12
+ 0·01 per cent α-tocopheryl acetate	170	92	70	22

E deficiency, its effect varying from species to species. Some syndromes, such as hepatic necrosis in the rat[4] and exudative diathesis in the chick[5], are prevented by either selenium or tocopherol. Other syndromes, such as gestation-resorption in the rat, are only preventable with tocopherol[6]; yet a third group of syndromes, such as muscular degeneration in lambs[7], may well be primarily selenium-deficiencies, only partially responsive to tocopherol. These differences must be explained if an understanding of the role of either compound is to be reached.

In a typical experiment, three groups of 8 female rats (3½ months old) were fed a 'necrogenic' fat-free yeast/sucrose diet designed to reduce tocopherol, selenium and ubiquinone in the animals' tissues to very low amounts. Rats in one group were dosed with 20 μgm. of selenium (as selenite) 48 and 24 hr. before death, and a second group with 5 mgm. of *dl*-α-tocopheryl acetate at the same times. The three groups were killed together. Hearts, uteri and ovaries were analysed by methods already described[8] (Table 1). Tocopherol-levels in heart and uterus were almost too low to measure; but the ovaries contained much tocopherol—being, with adrenals, the last tissue in the body to retain stores of tocopherol[8]. The ubiquinone concentration in deficient heart was very low, but was increased to high levels with α-tocopherol. Selenium had a similar effect (but less marked, due to the smallness of the dose). Selenium and tocopherol both markedly increased ubiquinone in the ovaries, but in uterus, although tocopherol was fully active in increasing ubiquinone, selenium was without effect. In another experiment groups of 6 female rats were reared for 10–12 weeks on a vitamin E-deficient diet. One group received a dietary supplement of 0·01 per cent *dl*-α-tocopheryl acetate, a second a supplement of 0·1 p.p.m. of selenium (as selenite), while a third group acted as controls. Both selenium and tocopherol increased ubiquinone in heart, kidney and liver; only tocopherol had an effect in uterus (Table 2).

While the reason for the failure of selenium to influence ubiquinone in the rat uterus but not in the ovary, which have a common blood supply, is unknown, it is not suggested that this is directly the reason for its failure to prevent fœtal resorption in the rat; nor do we believe that ubiquinone enhancement in uterus by tocopherol explains the latter's action in preventing resorption. Rather, we regard the ubiquinone effect as diagnostic evidence of the ability or otherwise of these two substances to reach the embryos, where ubiquinone synthesis at a certain stage might be extremely critical. This work will be reported in full elsewhere.

Tocopherol, Ubiquinones and Ubichromenols in Yeasts and Mushrooms

DURING work on vitamin E, we have been interested in obtaining animal diets rigorously freed of tocopherol. Methods of analysis now available[1,2] allow amounts of tocopherol much less than 1 μgm./gm. of diet to be determined and have already shown that many constituents of 'vitamin E-free' diets in fact contain appreciable amounts of tocopherol. Of particular interest is yeast, which has usually been held to be devoid of tocopherol (for example, Forbes and György[3]). When several kinds of commercial dried bakers' yeast were analysed by the above methods they were found to contain small quantities of α-tocopherol (of the order of 0·3 μgm./gm.) Eventually, fresh compressed bakers' yeast (Distillers Co., Ltd., 3 kgm.) was lysed by a method[4] using diethylamine as catalyst, and the solid residue was extracted with hot ethyl acetate. The extract was purified and analysed[1] for α-tocopherol, ubiquinone-30 and ubichromenol-30. In Table 1 the results are compared with those found on a replicate batch of yeast autolysed with ethyl acetate and extracted with hot benzene–alcohol (a method[5] used for ergosterol). It would appear that the former method is superior to the latter. The ubichromenol-30 was identified by comparing it with a synthetic specimen, prepared from ubiquinone-30 by Links's method[6]. Certain batches of yeast appeared to contain ubiquinone-35 instead of ubiquinone-30. The identity of the α-tocopherol was confirmed by isolating it chromatographically. The substance was strongly reducing, ran identically with α-tocopherol in two chromatographic systems, had an ultra-violet maximum at 291 mμ and an infra-red spectrum consistent with it being α-tocopherol.

Since it appeared possible that the tocopherol might have been of exogenous origin, samples of beet and cane molasses (the main organic constituents used for the commercial production of this yeast) were examined. Several hundred grams of each, dissolved

Table 1. TOCOPHEROL, UBIQUINONE AND UBICHROMENOL IN YEAST, ETC.

* A special yeast produced for high content of vitamin B.
D.C.L., Distillers Co., Ltd.

in water, were extracted in a continuous extractor with ethyl acetate. Analysis of the extracts showed that cane molasses did in fact contain a little α-tocopherol (Table 1), but beet molasses did not. In order to arrive at an unequivocal answer to the problem of the origin of yeast tocopherol, a culture of the commercial yeast was grown in the laboratory on a medium in which the only energy source was pure sucrose. Analysis of the compressed cake (300 gm.), lysed with diethylamine as before, confirmed the presence of α-tocopherol (identified as previously). Considerably more ubiquinone than in the commercial sample was also found, the increase probably being due to the more efficient aeration used in the laboratory, as found by Sugimura and Rudney[7].

Torula yeast (*Torula utilis*) has also been widely used as a constituent of vitamin E-free diets. Two commercial samples of dried *Torula* yeast (Lake States Yeast Corp.) were examined. They both contained considerable α-tocopherol, and were remarkable because of their large ubiquinone and, in particular, ubichromenol contents (Table 1). Yeast is the first natural substance we have so far encountered in which the concentration of ubiquinone is exceeded by that of ubichromenol. The latter is clearly the unidentified tocopherol-like substance previously reported in yeast by Cowlishaw and Prange[8]. Paper chromatographic separation of the *Torula* extracts revealed 3 ubiquinones and 3 ubichromenols. The former consisted mainly of ubiquinones-45 and -35, as already described[9], with a trace of ubiquinone-30. The three ubichromenols were isomeric with the quinones. All six substances were compared chromatographically with authentic samples, followed by individual isolation and determination of their ultraviolet spectra. A sample of British *Torula* yeast was examined (Table 1) and found to contain considerably less of the lipid constituents. However, this yeast also contained more ubichromenol than ubiquinone.

The common mushroom (*P. campestris*) contained amounts of ubiquinone, ubichromenol and α-tocopherol very similar to those in bakers' yeast (Table 1). It seems, therefore that, although in a previous survey[10] it was suggested that the synthesis of α-tocopherol might be limited to chlorophyll-containing organisms, this view can no longer be held.

We wish to thank the Lake States Yeast Corp., Rhinelander, Wisconsin, for their generosity both in providing specimens of *Torula* yeast and their useful information; also Distillers Co., Ltd., for kindly giving us samples of their cane and beet molasses. We also thank S. A. Price and L. Gare of these Laboratories, who provided us with yeast grown on a defined medium.

An Unidentified Ubichromenol-like Lipid Constituent of Bakers' Yeast

DURING investigations of the unsaponifiable fraction of bakers' yeast (Distillers Co., Ltd.) by two-dimensional chromatography[1], a heavy spot was observed on the papers in a position very close to that expected for ubichromenol-30, which substance is present only in very small amounts in this yeast (preceding communication). The new substance was —like ubichromenol-30—slowly reducing to ferric chloride–dipyridyl; but, on papers pretreated with zinc carbonate containing a trace of sodium fluorescein[2] is weakly fluorescent under ultra-violet light, whereas the ubichromenol is observed as a quenching spot under the same conditions. By a combination of adsorption and reverse-phase partition paper chromatography, a few milligrams of the substance were obtained in a reasonable state of purity. Long runs in two reverse phase paper systems (*a*) liquid paraffin/95 per cent ethanol, and (*b*) olive oil/95 per cent ethanol, clearly distinguished the new substance from ubichromenol-30; the R_F values for these two substances in the latter system were 0·64 and 0·46, respectively. The new substance had absorption maxima at 255 and 282 mμ, with minima at 267 and 315 mμ (in ethanol). In the presence of dilute ethanolic alkali, the 282-mμ peak disappeared and a new peak at 345 mμ appeared. Well-defined isosbestic points occurred at 271 mμ and 322 mμ. These changes are similar to those described[3] for ubichromenol-50, with some displacement of the points, and probably indicate the presence of a phenolic OH grouping as in the latter. The infra-red spectrum had bands at ν 2,899, 2,809, 1,455, 1,373, 1,261, 1,208 and 1,059 cm.$^{-1}$, similar to those found in a specimen of ubichromenol-50 (kindly given by Prof. R. A. Morton). Substance 282 (so-called because the single peak at 282 mμ characteristically distinguishes it from the ubichromenols) was chromatographically distinct from the fluorescent substance, 3-formylindole, which is present in certain animal tissues[4] and has $\lambda_{\max.}$ 282 (in cyclohexane) and $\lambda_{\max.}$ 294 (in ethanol). Substance 282 was found to be strongly active, like α-tocopherol, in the *in vitro* erythrocyte hæmolysis test.

Forbes and György[5] have already isolated from bakers' yeast a blue fluorescent substance, which has some vitamin E-like activity and is also strongly active in the hæmolysis test. This substance has been identified[6] as 2-(6-hydroxy-2-methoxy-3,4-methylenedioxyphenyl)-benzofuran and is clearly distinguishable from substance 282 on chromatographic and spectral evidence. In fact, those are not the only two fluorescent substances in the non-saponifiable fraction of bakers' yeast: yet a third non-reducing substance, strongly fluorescent, is present and has chromatographic properties almost identical with those of α-tocopherol.

It is interesting that substance 282 occurs in bakers' yeast and also in the mushroom (*P. campestris*), both of which contain very little ubichromenol. *Torula* yeast, on the other hand, which contains much ubichromenol (preceding communication), contains no detectable substance 282.

Electrophoretic Behaviour of Rat Serum Amylase

Determinations of the electrophoretic behaviour of human serum amylase[1] showed that the largest amount of amylase migrated with the albumin fraction and that a significant amount also migrated with the γ-globulins. Our preliminary observations[2] indicated that this was not the case for rat serum. The Delcourts[3] found that this was also not true for mouse serum, where about 75 per cent of the total serum amylase migrated with β_1- and β_2-globulins.

Sera were obtained from both normal rats and those suffering severe liver damage from treatment with N-nitrosodimethylamine[2,4]. The proteins of these sera were separated by paper electrophoresis with a Spinco paper electrophoresis apparatus, Model *R*, using a new filter paper, Schleicher and Schuell 2043*A gl*, thinner than the Whatman paper previously used[1]. The protein fractions were eluted with 0·9 per cent sodium chloride and analysed for amylase by a micro modification[1] of Van Loon's amyloclastic method[5].

As indicated in Table 1, the largest fraction of the serum amylase recovered was that associated with the β-globulin (70 per cent) and a lesser amount (about 25 per cent) with the γ-globulins, a pattern somewhat similar to that found for mouse serum[3]. The leading fractions contained amounts so small as to be almost insignificant. With sera from rats with liver damage, the amylase in the β- and γ-globulin fractions was reduced to less than 30 per cent of that in the normal sera, while the very small amounts in the albumin and α-globulin fractions remained essentially the same as in the normal.

Table 1. Distribution of Amylase in Rat Serum

Serum fraction	Amylase units/100 ml. serum	
	Normal*	N-nitrosodimethylamine* treated
Albumin	24	35
α_1-Globulin	19	19
α_2-Globulin	31	26
β-Globulin	1,012	287
γ-Globulin	337	93
Total of all fractions	1,443	460

* Five animals in each group. Duplicate determinations on each animal.

The fact that liver damage leads to marked reduction in the amylase of the β- and γ-globulin fractions might be interpreted as indicative that the amylase normally found in these fractions is produced in the liver. Because of the uncertainties in the interpretation of measurements of paper electrophoresis caused by protein–protein and protein–paper interactions, we would be cautious about making this interpretation unequivocally from these data alone. However, this interpretation would strengthen our previous conclusion from other data[2,6,7] that the liver is a source of amylase production.

Whatever the conclusions concerning the relationship of the liver to serum amylase, we wish to point out that the distribution pattern of serum amylase may vary from one species to another. That for the rat is definitely different from that for man.

Identification of 3,4,5-Trimethoxyphenylacetic Acid as the Major Metabolite of Mescaline in the Dog

Mescaline (3,4,5-trimethoxyphenylethylamine), an alkaloid obtained from *Anhalonium lewinii* and *Trichocereus terscheckii*, has been the subject of many investigations. After oral administration of mescaline to dogs, Slotta and Müller[1] were able to isolate 38 per cent of the mescaline as 3,4,5-trimethoxyphenylacetic acid but were unable to detect any of the parent compound in the 24-hr. urine. These results could not be confirmed by Cochin and co-workers[2], who reported that only 'trace' quantities of 3,4,5-trimethoxyphenylacetic acid were excreted in this species, but that 28–46 per cent of a dose, administered parenterally or orally, was excreted as the parent compound. Others[3-6] have reported similar findings of unchanged mescaline in the urine of human beings receiving the drug. The metabolism of this drug was re-investigated in the dog employing 8-^{14}C mescaline.

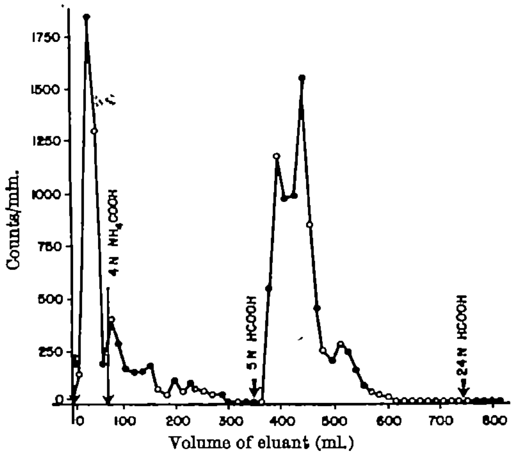

Fig. 1. Fractionation of acidified urine on 'Dowex-1' formate resin

Labelled mescaline (15 µc.) in a dose of 20 mgm./kgm. was administered intraperitoneally to mongrel female dogs anæsthetized with pentobarbitone sodium (35–40 mgm./kgm.). Urine was collected via an indwelling Foley catheter. Aliquots of urine (0·1–1·0 ml.) were combusted and assayed for radioactivity in a 250-ml. ionization chamber (Nuclear-Chicago model 6000). Excretion of radioactivity was determined for periods up to 13 hr. following administration of labelled mescaline. The values for radioactivity excreted during these experiments range from 55 to 62 per cent. Peak urinary excretion of radioactivity occurred within 2 hr. after administration of the drug.

Fractionation of acidified urine (pH 2–3) on 'Dowex-1' formate resin revealed the presence of two major peaks of activity (Fig. 1). The first peak of radioactivity when re-chromatogrammed on Whatman No. 52 paper (solvent system: water/acetic acid/butanol, 4 : 1 : 4) demonstrated an R_F value of 0·71–0·74, whereas mescaline had an R_F of 0·72 when chromatogrammed under similar conditions. The second peak of radioactivity, representing approximately 60 per cent of the excreted radioactivity, was eluted from the resin column with 5 N formic acid and had an R_F value of 0·91–0·92 when examined by paper chromatography.

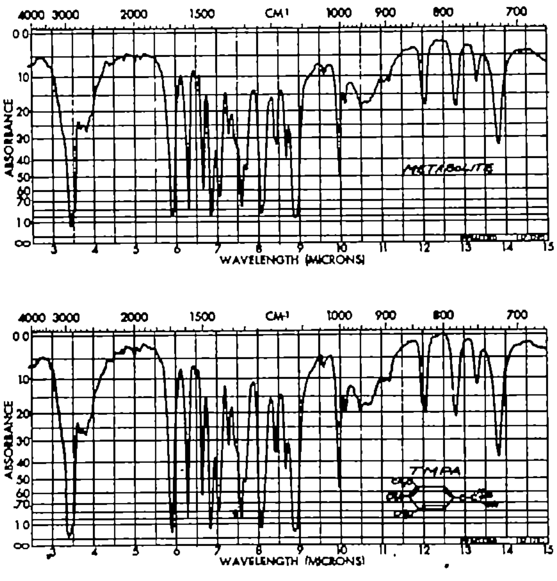

Fig. 2. Infra-red spectra of trimethoxyphenylacetic acid and metabolite of mescaline isolated from the urine of the dog

Acidified, unfractionated urine, or material corresponding to the second peak of resin-fractionated urine, was extracted with chloroform and/or diethyl ether. After evaporation of the latter solvent, the residue was washed with petroleum ether ('Skellysolve B') and then sublimed under vacuum. White crystalline material, melting point 118–119·5° C., was obtained. A mixed melting point with authentic 3,4,5-trimethoxyphenylacetic acid (melting point 118·5° C.) showed no depression. The infra-red absorption spectra of the metabolite and authentic 3,4,5-trimethoxyphenylacetic acid were identical (Fig. 2). Elemental analysis of the metabolite revealed the following values: found: C, 57·51; H, 6·10; N, 0·0; O (by difference), 36·39; calculated: C, 58·40; H, 6·20; N, 0·0; O, 35·40.

These results clearly indicate that deamination with resultant formation of a carboxylic acid is the major pathway of metabolism of mescaline in the dog, but that a significant amount of unchanged drug is also excreted in this species.

I wish to thank Dr. Raymond M. Hainer, Arthur D. Little, Inc., Cambridge, Massachusetts, for help in interpreting the infra-red observations and for several helpful discussions, and Dr. S. B. Leavitt for assistance in these experiments. This work was supported by grant M-2539, Public Health Service, National Institutes of Health, Division of Research Grants.

Method of dissolving Triacetyloleandomycin for the Assay of Sensitivity of Micro-organisms

The usual *in vitro* tests of the sensitivity of bacteria to antibiotics are not applicable to triacetyl-oleandomycin (TAO), known in Great Britain as 'Evramycin' and in the United States as 'Cyclamycin', since it is almost insoluble in water. In spite of this, TAO is known to be clinically effective, and after oral administration it attains a high concentration in the blood.

It seems that in order to enter the blood-stream and to reach the peak-concentration in as short a time as about 2 hr., this antibiotic must be converted into an absorbable form very soon after ingestion, either in the stomach or in the upper segment of the intestine.

My experiments *in vitro* showed that TAO is insoluble in the duodenal juice, but it dissolves readily in the gastric secretion, samples of filtered, unfiltered and also of boiled gastric juice being equally effective solvents. This suggests that gastric hydrochloric acid is the effective substance.

TAO dissolves readily in $N/10$ hydrochloric acid (a concentration corresponding to that found in normal gastric juice), but neither gastric juice nor $N/10$ hydrochloric acid could be used as solvents of TAO for assays of sensitivity, since these reagents alone produce narrow zones of inhibition of bacterial growth and may cause considerable alteration and discoloration of complex media.

A series of tests with a wide range of hydrochloric acid concentrations showed that $N/100$ hydrochloric acid had no effect on media or micro-organisms, and dissolved TAO satisfactorily. To provide a margin of safety, however, $N/200$ hydrochloric acid is recommended as the solvent for TAO in sensitivity assays.

Triacetyl-oleandomycin requires an acid medium for its solubilization, and because of this one may speculate whether the speed of absorption and effectiveness of this antibiotic could be increased by dissolving it beforehand or supplementing it with dilute hydrochloric acid during its oral administration, especially in patients with achlorhydria or hypochlorhydria.

Crystalline α-Kojibiose

Kojibiose (2-O-α-D-glucopyranosyl-D-glycopyranose) was first detected in saké and its moromi[1], and it was isolated from hydrol[2], koji extract[3] and honey[4] as its crystalline α- and β-octaacetates. Chemical synthesis[5],[6] of this sugar was also achieved. But the crystallization of free sugar was hitherto unsuccessful, so its properties such as melting point, specific rotation or its form of crystal were still unknown. We have now succeeded in crystallizing kojibiose and examining its properties.

The same method as reported previously[7] was used for preparation of the kojibiose; but in this work the culture medium of *Leuconostoc mesenteroides* contained sucrose (9 per cent) and lactose (15 per cent) instead of sucrose (2 per cent) and lactose (10 per cent), and then a branched trisaccharide (O-β-D-galactopyranosyl-(1 → 4)-O-[α-D-glucopyranosyl-(1 → 2)]-D-glucopyranose) and lactosucrose[8],[9] (O-β-D-galactopyranosyl-(1 → 4)-O-α-D-glucopyranosyl-(1 → 2)-D-β-fructofranoside) were obtained together. After removal of most of the lactose and dextran by addition of an equal volume of ethanol, the supernatant was concentrated and fractionated by carbon column chromatography. 95 gm. of lactosucrose and 140 gm. of the branched trisaccharide contaminated with a small amount of lactosucrose were obtained from 15 litres of the culture medium. The contaminated lactosucrose in the branched trisaccharide fraction was hydrolysed to lactose and fructose with 0·5 N sulphuric acid at 60° C. for 30 min. and was removed by carbon column chromatography. 97 gm. of the branched trisaccharide was obtained. 10 gm. of the lactase preparation of *Saccharomyces fragilis* (kindly supplied by Dr. Henry Roberts) and 90 gm. of the above branched trisaccharide were incubated in 1 litre of phosphate buffer (pH 6·2), and 48 gm. of amorphous kojibiose was obtained by carbon column chromatography.

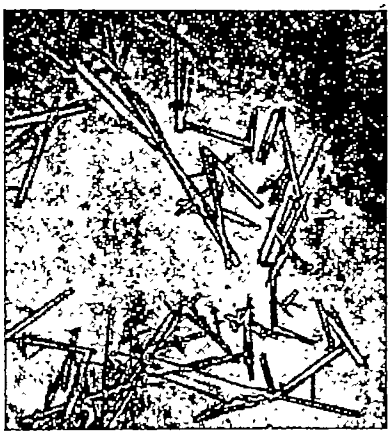

Fig. 1

This crude kojibiose was dissolved in 200 ml. of hot methanol, and the solution was refluxed gently, followed by filtration of the insolubles on 'Celite', and was left to cool at room temperature and then the kojibiose crystallized, 30·5 gm. of crystalline free sugar was obtained. Recrystallization was carried out by dissolving 10 gm. of the above crystals in 15 ml. of hot water and adding 35 ml. of methanol after being decolorized with charcoal. The crystals obtained took the form of fine prisms (Fig. 1). On drying in vacuum at 100° C. for 2 hr. over phosphorus pentoxide, crystalline kojibiose, which was somewhat hygroscopic, showed a melting point of 187–88° C. (uncorrected) and $[\alpha]_D^{18} = +162° \rightarrow 137°$ (17 hr.) (c., 2·1 in water) (calculated for $C_{12}H_{22}O_{11}$: C, 42·11; H, 6·48 per cent; found: C, 42·22; H, 6·48 per cent). The downward mutarotation showed that this crystalline kojibiose was α-isomer. This fact was further confirmed by formation of its acetyl derivative. Namely, only α-kojibiose octaacetate (m.p. 166° C.) was obtained when the acetylation was carried out at a low temperature by using pyridine as catalyst, while both α-kojibiose octaacetate (m.p. 166° C.) and β-kojibiose octaacetate (m.p. 117° C.) were obtained by the usual method using sodium acetate. Neither acetate showed depression of melting point on admixture with the authentic samples synthesized chemically by Matsuda[5].

PHYSIOLOGY

Plastic Changes of Spinal Monosynaptic Responses from Tenotomized Muscles in Cats

In an attempt to reduce muscle afferent activity, the tendons of some hind-limb muscles of cats were cut. It was postulated that this would prevent the development of effective tension, reduce passive stretching, and so induce relative disuse of the central synaptic connexions of the muscle afferent nerves.

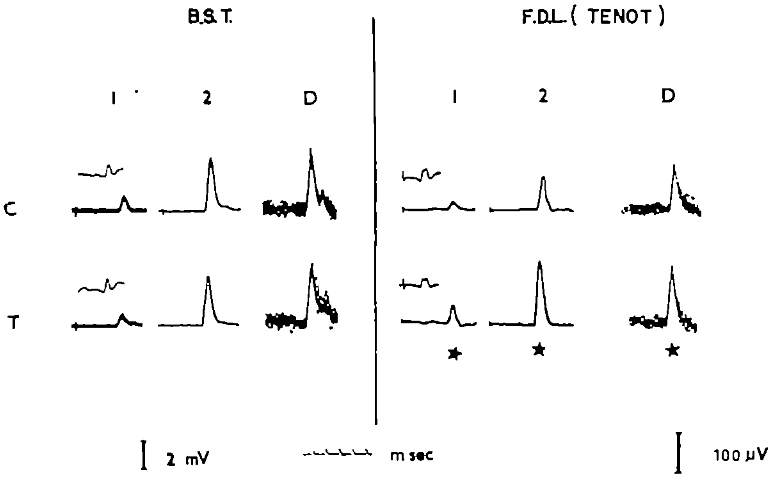

Fig. 1. All reflexes in this figure were taken from one typical experiment. Columns 1 and 2, respectively, are monosynaptic reflex responses for each nerve recorded from *L7* ventral roots before and after tetanic conditioning at 400 c./sec. for 10 sec. The afferent volleys from the cord dorsum are inset. *C*, Control side; *T*, tenotomized side. Biceps-semitendinosus nerve (*B.S.T.*) provided a bilateral control. Flexor digitorum longus (*F.D.L.*) was tenotomized. Dorsal spinocerebellar tract responses occupy columns *D*. Stars indicate enhanced responses from tenotomized muscle

At initial aseptic operations of 23 cats (inset Fig. 2) tenotomy was performed by excising about 10 mm. of the tendons of the following muscles on one side: triceps surae, flexor digitorum longus, and flexor hallucis longus. A dummy operation was made on the contralateral side.

One to four weeks after tenotomy, the spinal monosynaptic reflex responses were tested by two methods during the final acute experiments under pentobarbitone anæsthesia.

(1) The skin of both hind-limbs and the back was formed into pools which were filled with warmed paraffin oil. The cut nerves from the tenotomized and also from the control muscles (biceps-semitendinosus, quadriceps femoris, and peroneal group) in both hind-limbs were stimulated electrically. The reflex responses were recorded monophasically from the central cut ends of ventral roots *S1*, *L7*, *L6*. Further details of methods are the same as those given in a previous communication[1].

(2) Monosynaptic responses in the dorsal and ventral spinocerebellar tracts were also recorded[2]. The dorsal funiculi were dissected off the spinal cord between *T12* and *L2*, and the remaining portion of the cord was then hemisected longitudinally[3]. Dorsal spinocerebellar tract responses to both group 1*a* and 1*b* afferent volleys were recorded from the ipsilateral half-cord[3], while the ventral spinocerebellar tract reflexes from only group 1*b* afferents were recorded in the contralateral half-cord[4].

In Fig. 1 the typical monosynaptic reflexes recorded monophasically from ventral roots show the symmetry of control reflexes evoked by biceps-semitendinosus volleys into both ventral roots By contrast reflexes evoked from the nerve to flexor digitorum longus muscle are, significantly, 50–100 per cent larger from the nerve to the tenotomized muscle (Fig. 1). Though the conduction velocities for the afferent volleys (inset) were equal, a slight shortening of the central latency (mean about 0·1 msec.) was observed in reflex responses evoked from nerves to tenotomized muscles. The results described for biceps-semitendinosus and flexor digitorum longus were duplicated by the other muscles tested. Fig. 2 gives further details. These results are in close agreement with those obtained by Beranék and Hnik[5], who used similar techniques.

Spinocerebellar tract responses evoked by biceps-semitendinosus and flexor digitorum longus volleys in the same experiment (Fig. 1) illustrate the pooled results shown in Fig. 2. There is symmetry of the control dorsal spinocerebellar tract responses from hamstring, peroneal, deep tibial nerves, and of the ipsilateral ascending mass discharges from a skin nerve, sural. The nerves to tenotomized muscles, however, show a 45–55 per cent enhancement of their dorsal spinocerebellar tract responses with no significant change in ventral spinocerebellar tract responses.

Since the dorsal spinocerebellar tract responses arise more from group 1*a* than 1*b* muscle afferent fibres and since ventral spinocerebellar tract has exclusively 1*b*

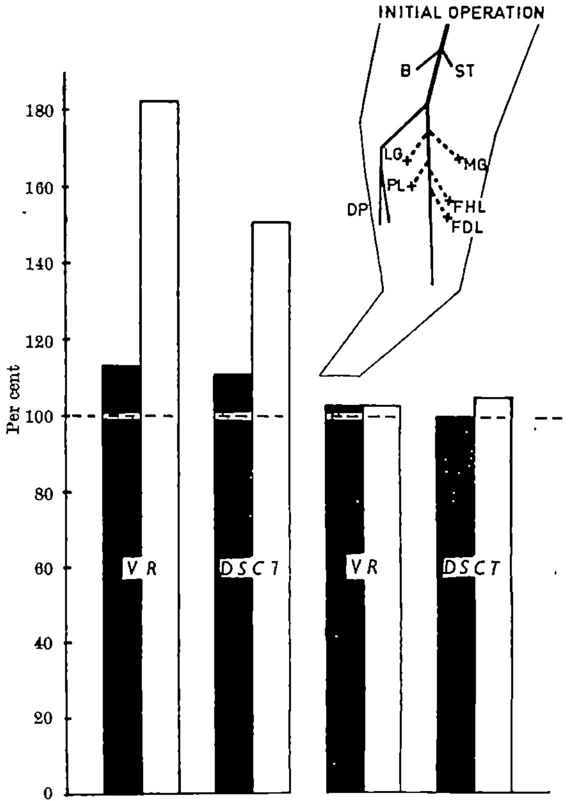

Fig. 2. Inset is a diagram of the initial operative procedure showing the nerves to tenotomized (+ – – –) and normal (——) muscles. Monosynaptic responses recorded from ventral roots *VR* and dorsal spinocerebellar tract response *DSCT* from ipsilateral half-cord. The results depicted in the histogram are averages of pooled reflex responses from 21 animals in the first group and 8 in the second group. The ordinate indicates the mean percentage ratio of corresponding reflexes from tenotomized side/normal side for the groups of nerves to normal (filled columns) and tenotomized (open columns) muscles. Thus 100 per cent indicates bilateral symmetry and a ratio of 1·00. The mean enhancement of *VR* and *DSCT* responses from tenotomized muscle is statistically significant, $P < 0·01$, and is prevented by spinal transection with tenotomy

connexions, our results suggest that the group 1*a* muscle afferents from the muscle spindle are responsible for the enhancement of dorsal spino-cerebellar tract monosynaptic reflex responses, which thus parallels the increased monosynaptic reflexes in ventral roots.

Comparison of muscle wet weight in both hind-limbs of all cats revealed that all muscle groups in the tenotomized leg wasted to some extent. The amount of wasting of tenotomized muscles themselves was much greater and persisted over several weeks, while control muscles on the tenotomized side began to recover their small weight losses after 9–10 days.

Since little is known of proprioceptor function in tenotomized muscles, preliminary attempts were made (in 40 muscles from 10 cats) to analyse the afferent activity from chronically tenotomized muscles by recording directly from the distal segment of cut muscle nerves. A significant 25–40 per cent increase was observed in spontaneous afferent spike discharges from chronically tenotomized muscles.

In further experiments transection of the spinal cord at *T*10–11 level immediately prior to tenotomy prevented, over the same period of survival, the development of both the reflex enhancements (Fig. 2), and the increased afferent discharges induced by tenotomy alone. This effect of cord section, which abolishes supraspinal gamma efferent activation, suggests that an over-active gamma loop mechanism could be responsible for the increased spindle discharges, which could lead to reflex enhancements.

We conclude from available evidence that tenotomy of muscle results in increase of the monosynaptic responses evoked by group 1*a* afferent volleys. There is some evidence suggesting that this effect is brought about by increased discharges of 1*a* impulses from the chronically tenotomized muscles, that is, that it is due to increased synaptic use. The effects are prevented by spinal cord-section (*T*10–11) at the time of tenotomy.

Role of Biliary Alkaline Phosphatase in the Guinea Pig

ALTHOUGH the part played by intestinal alkaline phosphatase in digestion and absorption is still not clear, it has long been postulated that the high concentration in the duodenum and intestine is concerned with the absorption of glucose[1]. Following adrenalectomy, Verzar *et al.*[2,3] showed that intestinal alkaline phosphatase was reduced and glucose absorption decreased. Administration of adrenal cortical hormones caused regeneration of the phosphatase.

Alkaline phosphatase is known to be secreted in the bile of mammals and it has been suggested that the biliary enzyme plays some part in digestion[4]. The present experiments were designed to see if there were any relation between biliary and intestinal alkaline phosphatase, in particular to see if the high concentration in the intestine were a result of the adsorption of biliary phosphatase by the mucosa. Such a system might be advantageous in replacing enzyme lost either by a mechanical rubbing off or by attack by digestive enzymes.

Duodenal alkaline phosphatase was therefore compared in normal guinea pigs and in guinea pigs in which the common bile duct had been tied and a gall bladder fistula made. In previous reports of guinea pigs with biliary fistulæ, the animals died within 24 hr.[4]. It was found that operated animals drank very little for the first 48 hr., and, as the daily output of bile from a fistula could reach 150–200 ml. (cf. 500 ml. for an adult man), a control of the fluid balance was planned in an attempt to increase survival times. In practice fluid was injected either subcutaneously or intraperitoneally. The fluid injected was Krebs's physiological saline containing vitamins C and K. In the absence of vitamin K, local hæmorrhages occurred.

Male guinea pigs were given vitamin K (0·1 mgm. 'Synkayvit') and vitamin C (10 mgm.) before their operation. The operation was carried out under nembutal and ether anæsthesia and at the beginning of the operation 20-ml. fluid was injected subcutaneously into the axilla. Immediately following the operation, 20-ml. fluid was injected intraperitoneally and a further 20 ml. given subcutaneously 1 hr. later. Thereafter injections of fluid were given at about 3-hr. intervals in an attempt to keep the body-weight constant. The flow of bile was considerably reduced after 48 hr. and it was found practical to maintain operated animals in a healthy condition for at least eight days.

A number of control and experimental animals were killed and duodenal samples rapidly removed. These were freeze-dried and embedded in paraffin wax *in vacuo*. After sectioning they were fixed in 90 per cent alcohol. The alkaline phosphatase of the brush border of the mucosal cells was estimated quantitatively by the method of Barter and Danielli[5]. Phosphatase activity was expressed in standard units of gm. phosphate hydrolysed per gm. of tissue per min. and the results obtained are shown in Table 1.

The results for operated animals show a consistently higher phosphatase activity compared with those from control animals which have not undergone operation. This result is opposite to that which would be expected if duodenal alkaline phosphatase was partly absorbed from the bile. The higher concentration found may indicate a reduced removal of duodenal phosphatase by mechanical or enzymic factors since the food intake of operated animals was lower than in the control animals. Alternatively, adrenal cortical hormones may have increased in the operated animals and caused the increase in duodenal phosphatase.

Table 1

Guinea pig	Period of biliary fistula (days)	Duodenal phosphatase in standard units			
		Proximal duodenum		Distal duodenum	
		Site 1	Site 2	Site 1	Site 2
1 (control)	—	0 050	0 048	0 09	0 064

Alkaline Phosphatase in Cell Cultures of Human Origin

IN an attempt to define some of the changes which cells undergo in adaptation to growth *in vitro*, work has been carried out on the metabolic and enzymatic activities of a variety of established cell cultures, mainly of human origin. For this work, cells were cultured in several media, including Eagle's medium[1] and *M*199 [2] containing 10 or 15 per cent undialysed human serum, or in a nutrient medium described by Marcus *et al.*[3] containing 20 per cent undialysed human serum. Cells were grown for 6–8 days on glass surfaces at 37° C. in an atmosphere of 5 per cent carbon dioxide in air, and dispersed with 0·05 per cent trypsin in saline. They were collected by centrifugation at 500*g*, washed and resuspended in 0·25 *M* sucrose, and disrupted with a 10-kc./s. Raytheon sonic oscillator for 1–5 min. Cell protein was measured by the procedure of Lowry *et al.*[4].

The initial findings confirmed observations made by Lieberman and Ove[5] with regard to the similarity in specific activities of catalase, glucose-6-phosphate dehydrogenase, rhodanese and β-glucosidase among cell-free preparations of various cell lines. On the other hand, a striking dissimilarity was noted in alkaline phosphomonoesterase activity as measured by the hydrolysis of *p*-nitrophenylphosphate in 1 *M* 2-amino-2-methyl-1-propanol buffer, at *p*H 10·6, according to Lowry's technique[6].

Table 1 summarizes the specific activities for alkaline phosphatase in sonicates of a variety of established human cell lines, including the parental and three clonal strains of the *Z* liver line derived from an infant with congenital atresia of the bile ducts, and of a recently explanted bovine embryonic kidney cell line. As can be noted, alkaline phosphatase activity with sonicates of the Chang liver line[7] is two-fold greater than that of human intestine[8], three-fold greater than that of *KB* (Eagle)[9] and anywhere from 25- to 200-fold greater than that of other cell lines. After one or two successive single cell platings according to the technique of Puck *et al.*[10] several clonal strains of Chang liver have been obtained which show differences in alkaline phosphatase activity. Sonicates of one of these clonal strains, which can be defined by the gross morphological characteristic of a smaller cell size, have a specific activity which is only 1/40 that of the parental strain.

Table 1. ALKALINE PHOSPHATASE ACTIVITY OF MAMMALIAN CELLS IN CULTURE

Cell line	Activity, *p*H 10·6
Chang liver	21·88*
Intestine (Henle)	9·65
KB (Eagle)	6·56
Z Liver-*P.S.*	0·53
Z Liver-1	0·15
Z Liver-2*A*	0·14
Z Liver-4*A*	0·84
HeLa-*S*3	0·12
HeLa-3218*A*	0·22
MAF (Gray)	0·71
Bovine kidney	0·19

* Specific activity = μ*M* *p*-nitrophenyl phosphate hydrolysed per mgm. protein in 30 min. at 38° C. in 1 *M* 2-amino-2-methyl-1-propanol – hydrochloric acid buffer, *p*H 10·6.

Separation of cell sonicates by differential centrifugation in 0·25 *M* sucrose[11] reveals the major portion of activity for all cell lines in the microsomal fraction. Extraction of a 10 per cent microsomal preparation with *n*-butanol[12] yields up to 9–10-fold purification of the phosphatase activity. Kinetic studies with the enzyme from the Chang liver microsomal fraction show the reaction to be zero order with the activity linearly dependent on enzyme concentration over a 100-fold range. The *p*H optimum is 10·6 with a decline to 10 per cent of maximal activity at *p*H 8·0. No activation with Mg^{2+} is found using *p*-nitrophenylphosphate as substrate, but inhibition is observed with Be^{2+}, Zn^{2+}, Mn^{2+}, CN^- and cysteine. Concentrations of 10^{-2} *M* inorganic phosphate are required for inhibition of activity. The enzyme exhibits a broad substrate specificity showing activity against *p*-nitrophenylphosphate, β-naphthylphosphate, β-glycerophosphate, adenosine monophosphate, glucose-6-phosphate and ethanolamine phosphate in decreasing order. Work is in progress to characterize further the physical-chemical properties of these enzyme preparations, some preliminary results of which indicate qualitative as well as quantitative differences in properties of enzymes derived from different cell lines.

During the course of this work, it was noted that the specific activity of alkaline phosphatase in Chang liver sonicates shows some variation over a four-fold

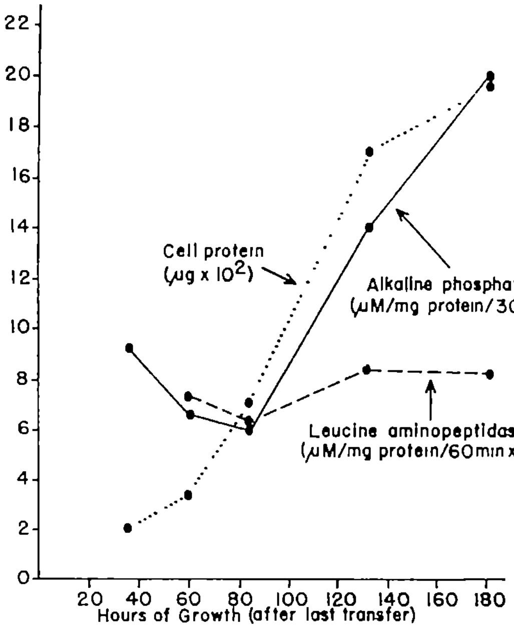

Fig. 1. Change in specific activity of alkaline phosphatase and leucine amino-peptidase in Chang liver sonicates with growth

range, although it is consistently higher than the activity of other cell lines. This variability can be correlated with the duration of growth following their last transfer, and in general, the longer the growth period the higher is the specific activity observed. These findings are illustrated in Fig. 1, where during a single growth-cycle of 180 hr., when cell protein increases ten-fold, the specific activity of leucine aminopeptidase remains constant but the specific activity of alkaline phosphatase rises to a value of 20·00 at 180 hr. of growth after falling from 9·50 initially to 6·00 at 84 hr.

Of interest are the recent observations of induced synthesis of alkaline phosphatase in *E. coli*[13,14], *B. subtilis*[15] and yeast[16] in response to removal of the repressor effect of inorganic phosphate in the growth medium. Preliminary work on inorganic phosphate concentrations in the nutrient medium reveal no alterations during the growth of Chang liver cells which can be correlated with the change of alkaline phosphatase activity. Work is now in progress to define more clearly whether an inducer or repressor mechanism plays some part in the differential activation or synthesis of alkaline phosphatase in these cells and whether such alterations, like those demonstrated by De Mars for glutamine synthetase[17], are characteristic of other enzyme systems.

This investigation was supported in part by grants from the National Institute of Arthritis and Metabolic Diseases of the National Institutes of Health, United States Public Health Service, and the National Association for Retarded Children.

Prevention by Vagotomy of Erythrocytosis induced by Hypoxæmia

WHILE investigating the effect of fluid aspiration into the lungs[1], observations were made on erythrocytosis induced by hypoxæmia, which to our knowledge have not yet been described.

Sheep were anæsthetized with 'Thiopentone', intubated, and given 1–3 ml./kgm. fresh water into the trachea. Before and 5 min. following the latter procedure, blood samples were taken from the femoral artery through an indwelling cannula. Arterial oxygen saturation, hæmoglobin and *p*H were determined and arterial oxygen tensions calculated. Observations carried out on 24 intact and 24 vagotomized sheep are reported here. Vagotomy was performed bilaterally on the neck prior to the control period.

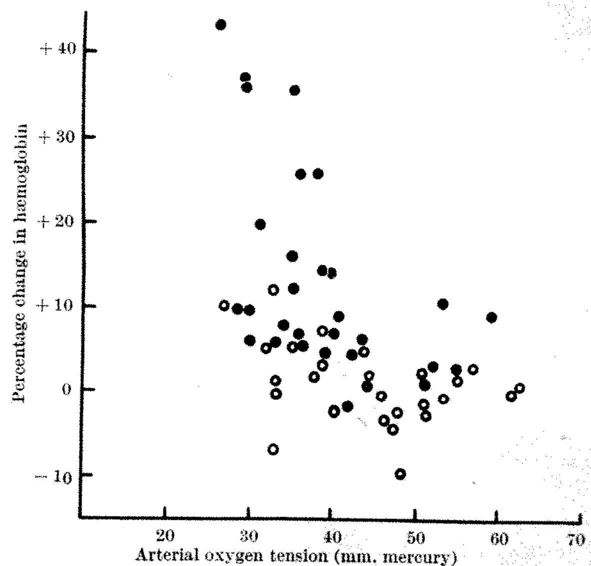

Fig. 1. Relationship of arterial oxygen tension and percentage change in hæmoglobin content in intact (●) and vagotomized (○) sheep 5 min. following the induction of hypoxæmia. Each dot represents one animal. Oxygen tension is given in mm. mercury

Results are shown on Fig. 1. The arterial oxygen tension 5 min. following the inhalation of water was related to the percentage change in hæmoglobin.

Water inhaled into the lungs is rapidly absorbed and remains unaffected by vagotomy[2]. Both groups were given strictly equal quantities of water; the resulting hæmodilution is therefore comparable.

Erythrocytosis appears to commence rather abruptly at an arterial oxygen tension of about 35–40 mm. mercury. This is in good agreement with earlier observations, suggesting a critical oxygen tension of 40 per cent.

In experiments reported in the literature, hypoxæmia was caused by the inhalation of gas mixtures low in oxygen. Alveolar oxygen tension in our animals was invariably normal[1]. It seems justifiable to conclude that arterial unsaturation is in itself a sufficient stimulus to mobilize the stored red cells in the body.

A comparable degree of hypoxæmia failed to cause erythrocytosis in our vagotomized sheep ($r = -0·153$; $P = 0·40$). The nerves were divided well below the carotid sinus: its denervation could scarcely have been responsible for the absence of the reaction.

Splenic[3] and hepatic contraction, and an increase in splanchnic blood-flow, appear to be the accepted mechanism of hypoxic erythrocytosis. Splanchnic stimulation is followed by similar changes, while electric stimulation of the peripheral end of the divided vagus was without an effect. The profound fall in hæmatocrit during anæsthesia[4] and following the administration of chlorpromazine and dihydroergotamine[5] is accompanied by an increase in the red-blood cell content of the spleen.

Barcroft and Stephens[3] suggested that splenic contraction is the effect of hypoxæmia on the central nervous system. Our observations would therefore suggest that it is the absence of an afferent impulse which accounts for failure to observe hypoxic erythrocytosis after vagotomy.

Relationship of the Sarcoplasmic Reticulum to Sarcolemma in Sheep Cardiac Muscle

SINCE Huxley and Taylor[1] demonstrated that in striated muscle each myofibril segment probably receives an individual stimulus to contract, electron microscope studies have suggested that the most likely pathway for such stimuli from the sarcolemma to the myofibrils is the sarcoplasmic reticulum[2], particularly[3] its transverse tubular elements (also named the 'transverse sarcotubular system'[4]). Theories about this have recently been elaborated and the evidence has been reviewed[5,6]. Such theories are necessarily based on the possibility that the membrane of the tubules is polarized and is capable of undergoing depolarization in the same way as the plasma membrane (inner layer of sarcolemma).

The question of continuity between plasma membrane and sarcoplasmic reticulum is a somewhat vexed one. Such continuity appears to occur in certain non-muscular cells[7,8], and it has been suggested or demonstrated also for both cardiac[2,9–11] and skeletal muscle[12,13]. This could not, however, be proved by serial sections in a major study of skeletal muscle[4], and the theories put forward[5,6] concerning impulse conduction by the sarcoplasmic reticulum are not based on a concept of communication between the lumen of the sarcoplasmic tubules and the extracellular fluid, although Huxley[14] favours such a concept on physiological grounds. Lindner[11] found that the transverse tubules in the dog myocardial cells had triple-layered membranes, like the sarcolemma, and he suggested that these tubules might be continuous with invaginations of the sarcolemma.

We have studied the fine structure of sheep cardiac muscle and we have found evidence of two types of tubular structure within the cell. One type is rather sparse in our material, possibly due to fixation artefact, and consists of delicate irregular small tubules, some of which are in contact (if not actual continuity) with the inner layer of the triple-layered sarcolemma (Fig. 1), in agreement with previously published work[5,9]. The other type is usually seen as cross-sections of tubules, lying between the myofibrils, usually opposite *Z* bands (Fig. 2). These tubules are comparatively large with triple-layered walls, identical in thickness and appearance to the sarcolemma. When the plane of section passes longitudinally between two myofibrils, the transverse tubules are cut longitudinally (Fig. 3), and the walls of some of the more superficial ones can be seen to be continuous with invaginations of the sarcolemma, as suggested by Linder[11]. We feel that the electron micrographs cannot be satisfactorily interpreted in any other way; complete proof of the continuity of the whole transverse tubular system and the sarcolemma will depend on a three-dimensional picture built up from serial sections, but the present findings go far towards confirming Huxley's theories[3,14] of muscle activation.

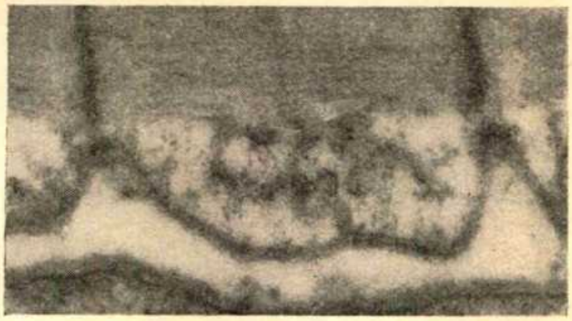

Fig. 1. Electron microscope (Siemens Elmiskop 1) photograph of edge of sheep myocardial cell. Part of a network of fine tubules can be seen, apparently continuous with the plasma membrane (inner layer of sarcolemma). (× 43,000)

This concept makes it much easier to accept the theory of a polarization of the sarcoplasmic reticulum, as it implies that this part of the sarcoplasmic reticulum is actually an integral part of the sarcolemma and necessarily undergoes the same electrical and chemical changes as the sarcolemma. The concept also implies that the lumen of this system of tubules is in communication with the extracellular space, and that the total area of sarcolemma (as Siekevitz[15] has suggested for other cells) is much greater than simply the external surface area of the cell. This may help to explain the great rapidity of the ionic fluxes which take place across the sarcolemma.

One may speculate further whether the alternate contraction and relaxation of the cell provide a pumping of extracellular fluid out of, and into, the system of tubules, and whether this might be of importance in the nutrition of the cell as well as in the electrical events of depolarization and repolarization.

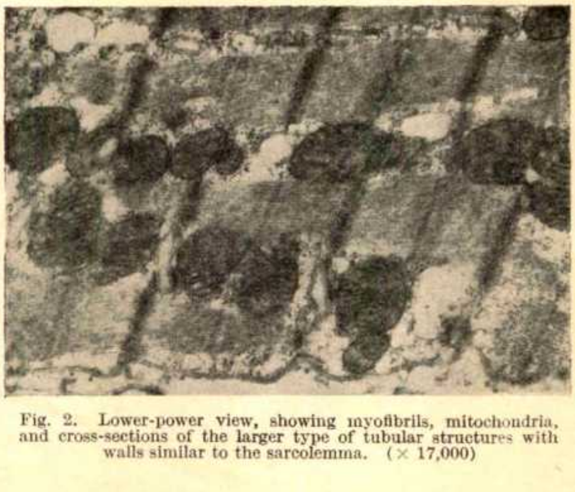

Fig. 2. Lower-power view, showing myofibrils, mitochondria, and cross-sections of the larger type of tubular structures with walls similar to the sarcolemma. (× 17,000)

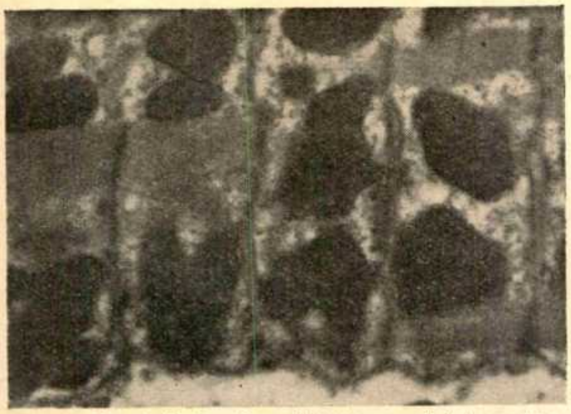

Fig. 3. Longitudinal section which has passed between two subsarcolemmal myofibrils. The walls of one of the longitudinally sectioned tubular elements are continuous with a sarcolemmal invagination, and the lumen communicates with the exterior. (× 12,000)

It is evident that this concept of myocardial cell structure will require a re-appraisal of the physiology of the myocardium and may help to solve some of the problems associated with the electro-chemical phenomena of the heart. It must be emphasized, however, that the present report is based on observations of cardiac muscle from the sheep only, and that the findings do not necessarily apply to voluntary muscle.

One of us (F. O. S.) is indebted to Dr. T. E. Lowe, director of the Baker Medical Research Institute, for suggesting this work, and to Dr. P. L. Bazeley, director of the Commonwealth Serum Laboratories, for access to electron microscope facilities.

Partition of Calcium and Phosphorus Excretion in the Laying Hen

THE need for surgery as a prerequisite to the separate collection of urine and fæces in birds has restricted our knowledge of their excretion pattern. Recently, the nitrogenous excretions of chickens have been investigated[1], but no data have as yet been published on the partition of calcium and phosphorus excretions. In order to study these excretions in laying hens, colostomies were performed by exteriorizing the distal end of the colon at a point between the ischium and the abdominal midline at the right side, approximately 1 in. anterior to the ventral lip of the cloaca, essentially as described by Ariyoshi[2]. In most birds the operation did not disturb egg production. For the collection of fæces, a polyethylene collar provided with a thread was sutured to the skin surrounding the exteriorized intestine, and a wide-mouth bottle of the same material screwed into the collar.

The hens received the following diet (quantities as percentages):

Table 1

Glucose	59·65	Choline chloride	0·1
Soybean oil meal	20	Vitamin mixtures (ref. 3)	0·25
Dried egg albumen	8	K_2HPO_4	1·1
Refined corn oil	3	$NaH_2PO_4.2H_2O$	1·1
Sodium chloride	0·3	$CaCO_3$	6·5

The assayed calcium and phosphorus contents of the diet were 2·64 and 0·50 per cent, respectively. The feed was supplied *ad libitum* from feeders specially constructed to minimize spillage. Water was supplied by a low-pressure drip system mounted overhead at the rear end of the cage, the 'founts' being activated by contact with the chicken's beak; this system minimizes feed wastage in water[4]. Daily measurements of calcium and phosphorus intake and excretion were done on four surgically prepared hens receiving this diet for seven consecutive days. Calcium was determined by a method using ethylenediamine tetraacetate as described elsewhere[5]. For the estimation of phosphorus the excreta were wet-ashed with 10 *N* sulphuric acid and 30 per cent hydrogen peroxide and phosphorus determined by Gomori's method[6].

The results are summarized in Table 2. The absolute amount of calcium appearing in the urine is similar to the amount of phosphorus, but as a percentage of the ingested mineral, 51 per cent of the ingested phosphorus appeared in the urine, whereas the corresponding average value for calcium was only 7 per cent. More than 58 per cent of the ingested calcium was deposited in the egg (most of it in the shell) and nearly all the calcium retained could be accounted for by the calcium of the egg. As a percentage of excreted mineral, 19 per cent of the excreted calcium and 62 per cent of the excreted phosphorus were found in the urine.

Table 2. CALCIUM AND PHOSPHORUS BALANCE IN COLOSTOMIZED HENS

	Calcium	Phosphorus
	(gm./hen/day)	
Consumption	3·00 ± 0·66*	0·57 ± 0·12
Excretion in fæces	0·95 ± 0·21	0·18 ± 0·03
Absorption†	2·05 ± 0·58	0·39 ± 0·12
Excretion in urine	0·22 ± 0·06	0·29 ± 0·02
Retention‡	1·83 ± 0·56	0·10 ± 0·10
Eggs§	1·75 ± 0·17	0·08 ± 0·00
Balance	0·08 ± 0·15	0·02 ± 0·02
	(Per cent)	
Absorption†	67·8 ± 9·9	67·0 ± 8·1
Retention‡	60·4 ± 10·7	15·5 ± 14·6

* Arithmetic mean ± standard deviation, calculated from individual values (4 hens for 7 days).

† Apparent absorption (consumption minus fæcal excretion) disregarding possible re-excretion of absorbed calcium and phosphorus into the gastro-intestinal tract.

‡ Consumption minus excretion in urine and fæces.

§ Each hen laid six eggs during the seven-day experimental period. The figures for eggs (and balance) denote the total values of the period divided by seven; the standard deviations are based on the averages for each hen thus obtained.

The average apparent absorption was similar for both calcium and phosphorus. It should be kept in mind, however, that the true absorption is probably higher, since the possibility of re-excretion of absorbed minerals into the intestinal tract must be considered. On the other hand, the retention and percentage retention of phosphorus were much lower than that of calcium, and showed a relatively higher variability. This higher variability of phosphorus retention may be connected with the need of the individual bird to draw upon bone material. Since the ratio calcium/phosphorus in bone (2·5 : 1) differs greatly from that required for egg formation (20 : 1), hens having a negative calcium balance, indicating the use of bone calcium for egg formation, are likely to have an excess of phosphorus at their disposal; this will lead to an increased urinary excretion of phosphorus and consequently a low retention of phosphorus, as calculated on the balance sheet. In fact, the only hen on a negative calcium balance (– 0·08 gm.) in this experiment excreted as much as 0·35 gm. phosphorus/day and retained only 0·03 gm.

RADIOBIOLOGY

Protective Action of Calcium Gluconate against After-effects of X-irradiation on Conidia of *Neurospora crassa*

AN increase in the survival of conidia of *Neurospora crassa* irradiated with X-rays has been found when calcium gluconate is added to the plating medium.

A colonial, microconidial, fluffy strain of *N. crassa* (*UA*–51) was grown on a minimal Vogel medium[1] containing 1 mgm. of calcium chloride per 10 ml. Conidia were harvested after incubation for seven days at 30° C. and suspended in distilled water with a final density of 5×10^6 cells per ml. Seven (10 ml.) samples were exposed to X-ray doses of 240, 720, 1,200, 2,400, 7,200 and 9,600 r. respectively (dose-rate 4 r./sec. at a distance of 25 cm. from the target of a Philips X-ray machine operating at 300 kV. constant potential, with a half-value thickness for the unfiltered beam of 5 mm. aluminium). The conidia from both the irradiated and control samples were plated on minimal medium with and without added calcium gluconate (15 mgm./10 ml.). The amount of light received by the conidia during plating was kept to a minimum and constant for all samples. Six replicate experiments were carried out at each dose. After plating, the conidia were incubated at 30° C. in darkness and germination counts were made on the fifth day.

The addition of calcium gluconate caused an increase in the germination of irradiated conidia when compared with that on the unsupplemented medium (Table 1). This increase in survival was observed at all dose-levels studied and was statistically significant ($P < 0·05$) in seven out of eight doses. The presence of calcium gluconate after irradiation, therefore, lessened the death-rate of spores. Unirradiated conidia showed no significant difference in germination on the two media.

Table 1. EFFECT OF CALCIUM GLUCONATE ON THE PERCENTAGE SURVIVAL OF CONIDIA OF *Neurospora crassa* IRRADIATED AT DIFFERENT DOSE-LEVELS

Dose-level (r.)	Germination of irradiated sample on minimal medium*	Germination of irradiated sample on minimal medium + calcium gluconate*	
0	100	98	
50	132†	196†	$P < 0·001$
240	76	151†	$P < 0·001$
720	46	96	$P < 0·001$
1,200	93†	98	$P < 0·8$
2,400	59	92	$P < 0·001$
4,800	34	79	$P < 0·001$
7,200	44	78	$P < 0·001$
9,600	40	76	$P < 0·001$

* Normalized to germination of unirradiated control conidia as 100. The irradiation experiments with different doses of X-rays consisted of six replicates, each replicate representing 40 conidial platings with a colony count of approximately 100 colonies per plate at zero *r*. The plating efficiencies of all 96 replicates were determined before irradiation, but these results have not been incorporated in this table, no significant differences ($P < 0·01$) having been observed.

† These figures were consistently high in all six replicates.

The plating efficiency of the unirradiated conidial cells is about 35 per cent. The germination of treated conidia has been expressed as a percentage of the germination of unirradiated control conidia. Thus, an increase in plating efficiency as a result of the treatments may appear as a germination percentage of greater than 100.

In addition to the protective action of calcium against the consequences of radiation injury, there was also evidence at certain doses of stimulation of germination by the radiation. In some cases this was seen as an increased efficiency of plating when compared with that at zero dose; in others it was apparent as a reduction in net death of conidia compared with that observed following lower doses (unpublished work). Thus, when conidia were plated on minimal medium without calcium gluconate, the survival percentage following a 50-r. exposure exceeded 100, and survival following a 1,200-r. exposure (while less than that at zero dose) was twice as great as at 720 r. The survival steadily decreased at doses higher than 7,200 r. (zero survival out of 10^6 conidia being obtained with 115,000 r.). Superimposed on the destructive effects of the irradiation there is apparently stimulation induced by radiation of conidia which would not otherwise germinate.

Rixon and Whitfield[2], in work involving increased survival of X-irradiated rats when treated with parathyroid extract, stated that protection against radiation death might be due to the ability of the hormone to increase serum calcium; they (Whitfield and Rixon, personal communication) believe that an increased calcium-level protects the irradiated cell by reducing leakage of cell components through the cell membrane.

The radiation experiments with conidia of *N. crassa* confirm the hypothesis that calcium is a potential protector against death arising from the effects of radiation, and the experiments reported below show that the protection is associated with the prevention of a radiation-induced increase in cell permeability.

Conidia were raised on a medium containing 1·5 mc. of phosphorus-32 per agar slant for 7 days.

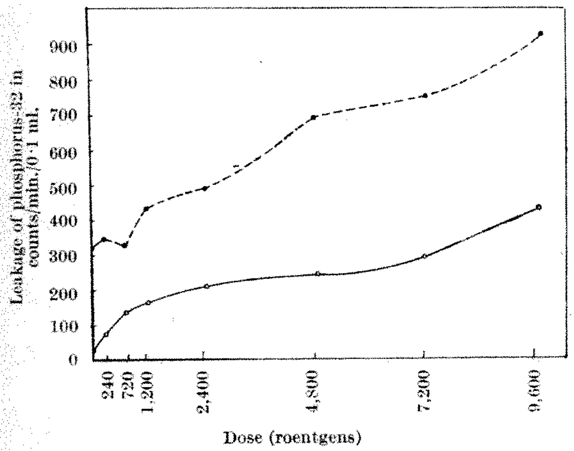

Fig. 1. Protective action of calcium gluconate against leakage of phosphorus-32 from conidia of *Neurospora crassa* after X-ray irradiation. ----, untreated; ———, treated with calcium gluconate

By the end of this time, there was 10^{-3} µµc. phosphorus-32/conidium. When these conidia were irradiated, there was a rapid release of phosphorus-32 into the medium (distilled water) in which the conidia were suspended. The magnitude of this leakage varied with the dose (Fig. 1).

When calcium gluconate was added to the medium on which the conidia were raised (25 mgm./10 ml. medium) (Fig. 1), and also when it was added to the distilled water in which the conidia were irradiated, the post-radiation leakage of phosphorus-32 could be largely prevented even when X-ray doses as high as 7,200 r. were used.

A detailed report of these experiments will be published later. The work was carried out in part during the tenure of a visiting professorship at the Biology Branch of Atomic Energy of Canada, Ltd., Chalk River (Ontario), and was supported in part by a research grant from the National Cancer Institute of Canada. My thanks are due to Dr. J. F. Whitfield and Dr. R. H. Rixon for their interest during these investigations.

Protective Effects of Di*iso*propylfluorophosphonate against the Lethal Effects of X-rays before or after Irradiation

Pre-treatment with di*iso*propylfluorophosphonate (DFP) suppresses the increase in permeability of the intestinal vessels of rats after abdominal irradiation[1,2] and similar vascular changes due to other types of injury[3]. DFP also reduces gastrointestinal symptoms (diarrhœa), which occur after exposure to X-rays. Since death from gastrointestinal injury is one of the well-recognized forms of acute radiation death, it was decided to test the effects of DFP on rats exposed to whole-body irradiation. Twenty rats were given 975 r. whole-body X-rays with a Philips X-ray apparatus (200 kV. 15 m.amp. 0·5 mm. copper, and 1·0 mm. aluminium filters, *F.S.D.* 30 cm. distance); ten of these animals received a prior injection of DFP before irradiation (3·0 mgm./kgm.).

The results of this experiment (Fig. 1) show that in the first three days after exposure to X-rays 60 per cent of the control, but only 20 per cent of the pre-treated animals had died. By 28 days, however, the same proportion of control and pre-treated animals survived. The early deaths (up to three days) were due to gastrointestinal injuries which manifested themselves in severe diarrhœa and its consequences, while the deaths in the second phase (six days and later) could be attributed to the lethal injuries to the hæmatopoietic system, thus confirming the well-established sequence of radiation deaths[4,5].

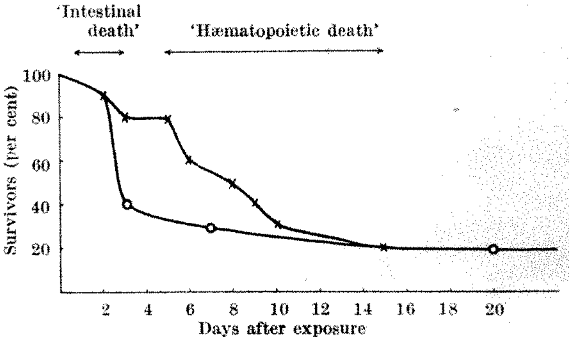

Fig. 1. Effect of DFP on whole-body irradiation. ×, treated with DFP; ○, X-rays only

Thus it appears that pre-treatment with DFP protected the rats against the 'intestinal death' but not the 'hæmatopoietic death'. To test this hypothesis further, rats were irradiated with various doses of X-rays over the entire abdomen, the rest of the animal being shielded so that most of the hæmatopoietic system was protected.

Table 1 indicates that treatment with DFP not only delays but also prevents death in a high percentage of rats exposed to doses of 1,050–1,334 r. of half-body irradiation. Of 60 rats receiving such doses of X-rays 95 ± 2·8 per cent died within four weeks, while of those treated with DFP only 65 ± 6·2 per cent succumbed (difference 30 ± 6·8). DFP proved ineffective when the dose of X-rays was increased to 2,200 r. The protective effect of DFP was the same whether administered before, immediately after exposure or 24 hr. after irradiation (Table 1).

Table 1. Effect of DFP Treatment on the Survival of Irradiated Rats (Abdominal Fields)

Dose (r.)	No. of rats	DFP treatment	Time to reach 50 per cent deaths (days)	Per cent deaths at 7 days	Per cent deaths at end of experiment (28 days)
1,050	12 ♂	0	5·5	58·0	82·5
1,050	12 ♀	0	4·0	75·0	100·0
1,050	12 ♂	Before X-rays	11·5	25·0	58·0
1,050	12 ♀	Before X-rays	11·0	25·0	58·0
1,050	12 ♂	0	5·0	75·0	92·0
1,050	12 ♂	Immediately after X-rays	11·0	33·0	58·0
1,334	12 ♂	0	3·0	92·0	100·0
1,334	12 ♂	Before X-rays	4·5	66·0	75·0
1,334	12 ♂	0	3·0	92·0	100·0
1,334	12 ♂	24 hr. after X-rays	5·5	50·0	75·0
2,200	12 ♂	0	3·5	100·0	100·0
2,200	12 ♂	Before X-rays	4·0	92·0	92·0

These experiments support the theory that DFP selectively protects rats from 'acute intestinal death' even if given *after* exposure to irradiation.

I am grateful to Dr. H. B. Fell and Dr. A. Glucksmann for their advice and encouragement. This work was done at the Strangeways Research Laboratory, Cambridge, during the tenure of a Wellcome Research Scholarship.

Differential Radiosensitivity in Rice (*Oryza sativa* Linn.) at the Genotypic Level

INFORMATION on differential radiosensitivity of genotypes of a gene locus is scanty[1]. During a course of investigations on the effects of pile radiation on rice, advantage was taken of an anthocyanin pigmented mutant appearing as a heterozygote for albinism in N_1 population of a variety *GEB*-24 to study the relative radiosensitivity of the genotypes at this locus. N_2 seedlings of the mutant segregated into greens and albinos in a 3 : 1 ratio. N_3 plants, homozygous dominant and heterozygous for chlorophyll character, segregated in 1 : 2 ratio, showing that the genes for albinism behaved as simple recessive to normal green. In the first of the two experiments, dry seeds from the heterozygous N_1 plant were irradiated with 5–40 kr. of X-rays from a therapy type X-ray machine operating at 250 kV., 30 m.amp., with 2·0 mm. copper. The seeds, stabilized for moisture content, were placed at a distance of 22·0 cm. from the target and at that distance the dose-rate was 309 r. per min. In the second experiment, in addition to those from the N_1 plant referred to above, seeds of one of its N_2 progeny, known to be homozygous dominant for green, were also irradiated. The dosage-range was 10–50 kr., and the dose-rate at a distance of 13·5 cm. from the target was 650 r. per min.

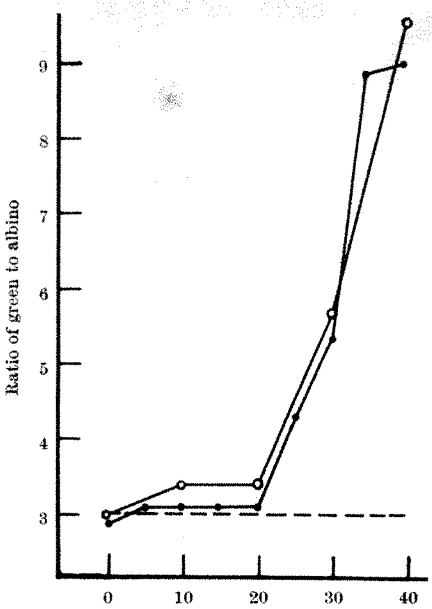

Fig. 1. Ratio of green to albino : – – – –, expected ; ●—●—●, observed in exp. 1 ; ○—○—○, observed in exp. 2

It can be seen from Table 1 that X-ray doses higher than 20 kr. had increasing effects on the rate of reduction of number of seedlings in both the experiments. It was further evident that with high doses the normal ratio, namely, 3 : 1 of green to albino seedlings, was also affected. As the dose increased, the rate of decrease of albinos in relation to greens became significantly higher, giving eventually 9 : 1 and 9·5 : 1 ratios for greens to albinos at 40 kr. in experiments 1 and 2 respectively (Fig. 1). It was evident that this was due to the greater lethality in the albinos, and the seeds carrying the recessive condition were more radiosensitive than the other two genotypes. It is of further interest to note that a difference existed between the homo- and heterozygotes for green in their degree of radiosensitivity. At the dose-level of 40 kr., there was more than four-fold decrease in emergence of seedlings in the mixed population of homo- and heterozygous greens as compared to the homozygous dominant. Presumably the greater radiosensitivity of the recessive gene is expressed even when it is in a heterozygous condition. Whether higher radiosensitivity in the recessive genotype was due to a pleiotropic effect or mutation of a closely linked gene

Table 1. EFFECT OF X-RAYS ON EMERGENCE OF RICE SEEDLINGS

Metabolism of Carboxyl-^{14}C-labelled 2,4-Dichlorophenoxyacetic Acid by Bean Stems: Heterogeneity of the Ethanol-soluble, Ether-insoluble Products

THERE is a considerable disagreement in the literature concerning the nature and number of radioactive metabolites which can be isolated from bean plants following exposure to 2,4-dichlorophenoxyacetic acid (2,4-D) labelled with carbon-14 (refs. 1–6). Because of this situation it was decided to re-investigate this problem in connexion with our work on the induction of callus growth in bean stem sections by 2,4-D (ref. 7).

The details of the preparation and isolation of the radioactive, water-soluble products from bean stems which were treated with carboxyl-^{14}C-2,4-D will be reported elsewhere. Briefly, bean stems were vacuum infiltrated with 2 per cent sucrose and 10^{-4} M carboxyl-^{14}C-2,4-D (2 mc./mM), surface sterilized by brief immersion in 0·5 per cent sodium hypochlorite solution, rinsed in sterile distilled water, and incubated in nutrient medium for 2 days. They were lyophilized, pulverized, and continuously extracted with wet acetonitrile. After removal of the solvent by distillation, ether-soluble material was extracted at *p*H 1·5, and sedimenting insoluble matter discarded. The aqueous layer was chromatographed on a 'Dowex-1' formate column using a gradient of increasing formic acid concentration. The radioactive peak was freed from formic acid and further purified by passage through a water-saturated silicic acid column using water-saturated 35 per cent *n*-butanol in chloroform as the eluting agent. The product was homogeneous by paper chromatography in the solvent of Jaworski *et al.*[4] and contained no detectable ninhydrin-positive contaminants.

When this material was absorbed on to a small amount of charcoal ('Nuchar') in a sintered glass funnel, the elution pattern shown in Table 1 was obtained. Separate re-application of each of these four fractions to fresh charcoal resulted in their elution at the same relative positions. When another aliquot of the purified material was applied to a charcoal column which differed from that described by Stambaugh and Wilson[8] only in that the column was doubled in length while column diameter and volume of eluting solvent were halved, the distribution of radioactivity shown in Fig. 1 was obtained. This pattern was very reproducible and suggests the presence of some 10 different components in this mixture. In practice, it was found that not all these materials were equally stable, and if great care was not taken during the chromatography on 'Dowex-1', there was considerable hydrolysis, resulting in the release of some radioactivity in ether-soluble form accompanied by the appearance of at least 10 distinct ninhydrin-positive materials in the water-phase. The remaining water-soluble radioactivity was eluted from charcoal only with 1 per cent ammonium in 25 per cent ethanol.

Table 1. ELUTION OF PURIFIED RADIOACTIVE, WATER-SOLUBLE AND ETHER-INSOLUBLE BEAN EXTRACT FROM 'NUCHAR'

A total of 3,000 c.p.m. were applied to 0·5 gm. charcoal. Three 10-ml. fractions were collected with each solvent

Solvent	Total c.p.m. eluted
Water	144
25 per cent ethanol (aqueous)	763
1 per cent NH_4OH in 25 per cent aqueous ethanol	1,496
50 per cent aqueous acetonitrile	306
Total recovered	2,709

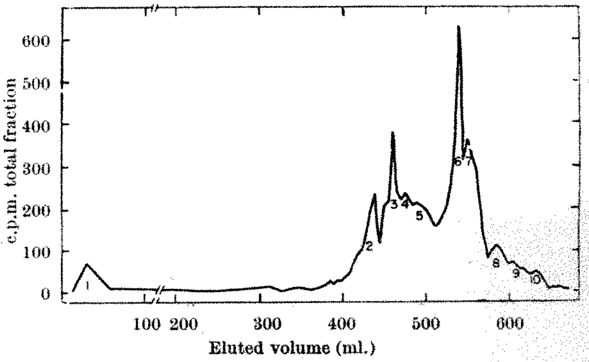

Fig. 1. The elution of radioactivity from 12-in. charcoal columns. 5 ml. fractions were cut between 350 and 700 ml. eluted volume

Holley[2] suggested that the ether-soluble hydrolysis product of the water-soluble bean fraction might be 6-OH-2,4-D, even though the compound was unknown at that time. Since then, 6-OH-2,4-D has been prepared by Cavill and Ford[9]. Using a small sample of this material, generously supplied by Dr. D. L. Ford, we found that it travels on paper indistinguishably from 2,4-D in the solvents previously used. However, when methylethylketone–conc. ammonium–water (100 : 5 : 3·2 v/v/v) was used the two compounds were readily separated. In this solvent the ether-soluble radioactive hydrolysis product from the bean extract was clearly separated from both these known substances (R_F: 2,4-D = 0·35; 6-OH-2,4-D = 0·61; bean extract hydrolysate = 0·0). Counter-current distribution of the ether-soluble material at *p*H 5·1 between phosphate buffer and diethylether resulted in the separation of four radioactive components. These results suggest that the previously reported main product of 2,4-D metabolism in beans[1–4] is indeed a complex mixture of amino-acid amides of several different and as yet unknown acid metabolites of 2,4-D. Further work towards the identification of these acids is in progress.

Excretion and Hepatic Storage of 5,6-Dimethylbenziminazolyl Cobamide Coenzyme labelled with Cobalt-58

Barker *et al.*[1,2] recently isolated a number of vitamin B_{12} derivatives from bacteria and demonstrated that they act as coenzymes in the conversion of glutamate to β-methylaspartate. Since the 5,6-dimethylbenziminazolyl cobamide coenzyme (DCC) was found to occur in rabbit liver[2], and to act as a co-factor in a rat enzyme system[3], it is reasonable to assume that the coenzymes are the forms in which vitamin B_{12} exists in the tissues and that the 'extrinsic factor' may largely consist of DCC and similar compounds. Since we have previously been engaged in research on the turnover of vitamin B_{12} (refs. 4 and 5), we thought it of interest to perform similar work on the turnover of radioactive DCC in man.

Four healthy student nurses who volunteered for the experiment were given an intragluteal injection of DCC labelled with cobalt-58. The preparation was kindly provided by the Squibb Institute for Medical Research, New Brunswick, New Jersey, and had a specific activity of about 1 μc. per μgm. The radioactive DCC was injected soon after its arrival from abroad and protected from light in order to minimize breakdown.

Three of the test subjects received a dose of 1 μgm. and one 0·75 μgm. in 1 ml. of physiological saline. The test subjects collected their excreta in one-day portions for 39 days (except on days off), and later fæces only during the seventieth to seventy-ninth day following the injection. The samples of fæces were incinerated at 600–800° C. in porcelain cups in a coal furnace in the boiler room of the hospital. Recovery experiments demonstrated that no loss of radioactivity occurred during this procedure. The urine samples were concentrated by evaporation. The ashes and the concentrates were counted in a well-type scintillation counter together with appropriate standards, and the radioactivity was expressed as mμgm. of the injected DCC.

Radioactivity counts were also taken over the liver area under standard conditions, once a day for the first 39 days, and once on the sixty-fifth day. The counts were corrected for radioactive decay.

The results of the excretion work are given in Table 1. It is seen that during the first few days after the injection the urinary excretion was slightly elevated, but later on the excretion of radioactivity was remarkably constant. From the fifth day on, urinary and fæcal excretions were about equal. The fraction of the total-body radioactivity lost per day was about 0·3 per cent or slightly less. This value corresponds to a biological half-life of about one year.

From the first day following the injection, relatively strong radioactivity was measured over the liver area, the counts ranging from 246 to 828 c.p.m. above the background ($\sim$410 c.p.m.). Maximum counts were observed within the first 12 days. During the 65-day period when liver counts were taken, there was no clear-cut decrease in hepatic radioactivity. Thus the hepatic biological half-life must be long.

On the whole, the results obtained with radioactive DCC are very similar to those observed after administration of radioactive vitamin B_{12}[4,6-8]. When radioactive DCC is injected there is possibly slightly less 'spill-over' of radioactivity into the urine in the days immediately following the injection. During later periods the excretion-rates and the total-body biological half-lives of the two compounds are very similar.

HÆMATOLOGY

Occurrence of Heparin in the Blood of Fish and its Prevention of the Clotting of Fish Plasma

The property of the blood of fish to clot rapidly provides a means of protection from fatal hæmorrhage such as may follow injuries[1]. Sometimes in the same fish the blood clotting-time is known to differ markedly at two different phases of its life-cycle. In the pre-spawning phase when the fish is fully laden with reserves, blood clotting is almost instantaneous, whereas during the period of physiological stress which generally follows spawning, clotting is slow and prolonged. Such variations in the coagulation-time have been attributed to some unknown factors which may involve a change in the chemistry of the blood of fishes[2].

Table 1. MEAN DAILY EXCRETION OF RADIOACTIVITY

The radioactivity is expressed as mμgm. of the injected preparation. *F*, fæces; *U*, urine; %, sum of fæcal and urinary excretions expressed as percentage of the radioactivity estimated to be contained in the body at the time of excretion.

Case Injected dose	*A* 1 μgm.			*B* 1 μgm.			*C* 1 μgm.			*D* 0·75 μgm.		
	F	*U*	%	*F*	*U*	%	*F*	*U*	%	*F*	*U*	%
1st–4th day	0·4	6·2	0·68	2·2	5·1	0·75	0·3	5·9	0·64	0·6	3·7	0·59
5th–39th day	1·5	1·1	0·28	1·0	1·4	0·26	1·0	1·4	0·26	1·1	1·1	0·32
70th–79th day	1·3	1·0*	0·29	1·2	1·7*	0·38	—	—	—	0·7	0·7*	0·24

* Because quantitative collection of urine for long periods is difficult, the subjects collected only fæces during this period. The urinary excretion was estimated on the assumption that the *U* : *F* ratio was the same as during the preceding collection period.

Heparin, the well-known anticoagulant, is a polysulphuric acid ester of a polysaccharide[3]. It has the remarkable property of preserving the fluidity of blood both *in vitro* and *in vivo*[4]; and for this reason in recent years there has been increasing recognition of its value in medicine and surgery[5]. The presence of heparin has generally been recorded in the blood and tissues of homoiothermous animals such as mammals which form the chief source for its extraction[6]. In poikilothermous animals and more particularly in fishes there appears to be no previous account of its occurrence and mode of action.

During a study of the hæmatology of the Indian freshwater murrel *Ophicephalus punctatus* (Bloch), blood samples were collected with a hypodermic syringe from the truncus arteriosus after pithing the fishes and exposing the heart. It then appeared that the clotting time of blood was short and that without the use of anticoagulants, suitable samples could not be obtained. A solution of peptone, as used by earlier workers in higher animals[7], was injected to liberate excessive quantities of heparin *in vivo*. This gave satisfactory results as the blood lost the power of clotting temporarily although the peptone solution in itself did not prevent clotting *in vitro*. It thus became evident that even in fishes production of heparin in order to maintain the fluid nature of blood was a natural phenomenon. Further tests were carried out to illustrate the presence of heparin in blood and its capacity to prevent the clotting of plasma.

Table 1

	Species : *Ophicephalus punctatus*		
	Normal	2 hr. after peptone injection	2 hr. after heparin injection
Prothrombin time at 37° C.	29·4 sec.	58·32 sec.	4 min. 42·5 sec.
Test with toluidine blue	Faintly positive	Positive	Strongly positive

Table 1 gives the plasma prothrombin time of *O. punctatus* by using standard methods[8] under the different conditions. The results indicate that the prothrombin time was prolonged after injecting 0·5 ml. of 5 per cent peptone solution per 100 gm. body-weight. It was considerably longer when the fishes were heparinized with 0·1 ml., heparin B.P., 1,000 I.U. per ml. for every 100 gm. body-weight. In both these cases intramuscular injections were given on the back. Each value given in Table 1 was obtained by using 10 individuals which each gave 2–3 readings. Tests with toluidine blue, as have been recommended for heparin[9], also gave positive results (Table 1).

It therefore seems certain that this remarkable anticoagulant occurs in the blood and possibly in other fish tissues also. It would be interesting to have more information about the piscine mast cells and their occurrence in various tissues, for these cells in other animals are known to secrete heparin[10]. The mechanism of action of heparin in fishes seems similar to that in higher animals[11]. It partly prevents the conversion of prothrombin to thrombin and partly antagonizes the action of thrombin itself. The co-factors such as plasma protein, serum albumin or heparin complement required for the action of heparin seem to be present in fish plasma.

We wish to thank Dr. S. Hameed, pathologist in the Institute of Ophthalmology of this University, for his help.

A New Hæmoprotein with a Unique Iron Porphyrin Prosthetic Group isolated from Human Erythrocytes

Hæmoglobin, comprising more than 95 per cent of the protein of the red cell, is the major protein in the mature human erythrocyte. The extremely high concentration of this compound in the red cell renders very difficult the identification of other hæmoproteins in the erythrocyte. Catalase is one hæmoprotein which has been isolated from erythrocytes. A third hæmoprotein, spectrally similar to hæmoglobin but which has been reported to be functional in the methæmoglobin reductase system, has also been reported[1,2]. It is the purpose of this communication to present observations on still another hæmoprotein which has been isolated from normal human erythrocytes. This compound is particularly noteworthy since its prosthetic group appears to be different from any previously reported naturally occurring iron porphyrin.

This hæmoprotein can be readily distinguished from hæmoglobin or catalase by its spectral properties as shown in Fig. 1. In its oxidized form the compound has no sharp absorption peaks in the visible region while in the Soret region of the spectra it has a typical hæmoprotein absorption with a maximum at 416 mμ. The cyanide derivative of this compound has a broad peak in the visible region with a maximum at 560 mμ and in the Soret region the peak is at 424 mμ. In contrast to catalase, the new hæmoprotein can readily be reduced with dithionite. The reduced form has absorption maxima at 560 mμ and 434 mμ.

Table 1 compares the position of the absorption maxima of the hæmoproteins known to occur in the red cell. A clear distinction can be made between

Table 1

Hæmoprotein	Oxidized	Absorption maxima		
		Cyanide	Reduced	CO reduced
Preparation	416	424	434	422
Catalase (ref. 6)	407	425	—	—
Myeloperoxidase (ref. 7)	430	458	475	—
Methæmoglobin	405	415	430	418

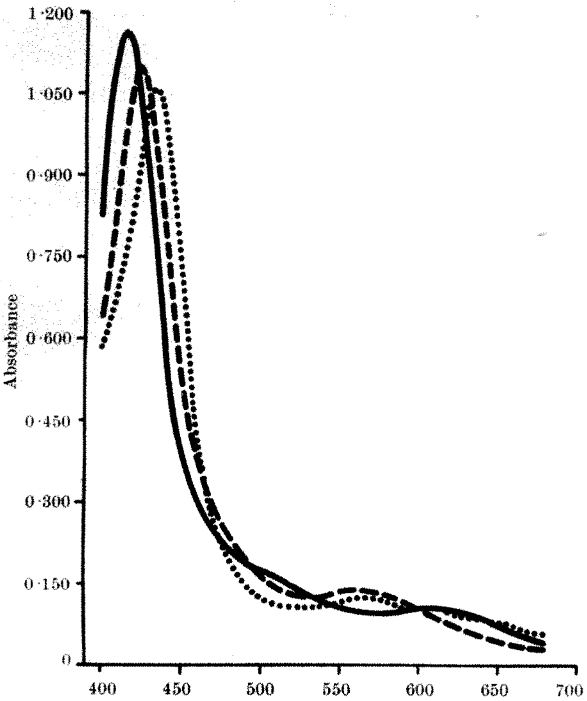

Fig. 1. ——, The hæmoprotein is dissolved in 0·1 *M tris*(hydroxymethyl) aminomethane buffer *p*H 7·2. The solution contained 2·2 mgm. protein per ml.; . . . . , the same preparation as described above to which has been added a few crystals of solid $Na_2S_2O_4$; – – –, the hæmoprotein preparation dissolved in 0·1 *M tris*(hydroxymethyl) aminomethane containing 0·01 *M* cyanide

the newly isolated hæmoprotein and catalase or hæmoglobin. It is also easily distinguished from myeloperoxidase, which might conceivably have been present if the white cells had not been completely removed in preliminary stages of the preparation.

The iron porphyrin prosthetic group of this compound appears to differ from that reported for any other hæmoprotein. Treatment of the preparation with acidified acetone as previously described[3] does not yield a hæmin which is extractable by ether. However, addition of pyridine and alkali to the hæmoprotein preparation does yield a hæmochromogen spectra. The reduced hæmochromogen has an α-peak at 572 mμ, β-peak at 535 mμ and γ-peak at 430 mμ.

A purified preparation of the hæmoprotein was analysed for protein by the biuret procedure[4] and the iron content was analysed as previously described[5]. Assuming that each molecule contains a single iron porphyrin moiety, the molecular weight was calculated to be approximately 67,500.

The hæmoprotein preparation did not appear to act as a peroxidase. No peroxidase activity could be attributed to the hæmoprotein when guiacol, dihydroxyphenylalanine or O-dianisidine were employed as hydrogen donors.

The preparation did not react with reduced di- or tri-phosphopyridine nucleotide. However, the hæmoprotein could be reduced by a highly purified reduced triphosphopyridine nucleotide diaphorase (Morrison, M., unpublished work), which was also prepared from the red cells. In enzymatic properties the diaphorase appears to be similar to the methæmoglobin reductase reported by Huennekens *et al.*[1,2] and required methylene blue in order to reduce the hæmoprotein. This suggests that the hæmoprotein may play some part in electron transport. However, the compound does not have the typical hæmochromogen spectra of a cytochrome. It combines with both carbon monoxide and cyanide, which indicates that if its does play a part in electron transport it may act as an oxidase.

The method of preparation and a more detailed account of the characterization of this hæmoprotein will be published elsewhere.

The work was supported in part by grant No. *H*-1322 from the National Heart Institute, National Institutes of Health.

HISTOLOGY

Mast Cells in Peripheral Nerve Trunks

References to mast cells occur only rarely in histological accounts of the structure of peripheral nerve trunks. They were mentioned by Cajal[1] and by Riley and West[2] in the perineurium of the rabbit and of the rat respectively, and in the looser connective tissues of the epineurium; they have been described in the endoneurium in the bony fish *Orthagoriscus mola*[3]. In injured nerve trunks, however, Cajal[1] has figured and briefly mentioned mast cells as elements of the endoneurium of the rabbit.

Recently we have studied thin (about 1μ) sections of rat sural and caudal nerves, stained with methylene blue after fixation in Dalton's fluid and embedding in 'Araldite' (a technique recommended to us by Dr. K. C. Richardson). Myelin sheaths, Schwann nuclei, etc., were stained as expected, but, in addition, large cells with metachromatically stained granules were frequently seen in the endoneurium as well as in the perineurium and the epineurium. Metachromatic granules or amorphous material frequently extended from these cells into the nearby tissue spaces between adjacent nerve fibres and as an inner lining to the 'endothelium' of the perineurium. Large metachromatically staining cells of this kind are also conspicuous elements in similarly fixed and stained longitudinal (10μ) sections of cat femoral nerve and mouse sciatic nerve. In the guinea pig sural nerve and in the splanchnic nerves of the rat and man they are also present but in smaller numbers. They are often seen in contact with small nutrient blood vessels, but many occur freely in the endoneurial tissues. In the rat nerves they constitute approximately 1·5–2 per cent of all the cells enclosed within the endothelium of the perineurium. They very closely resemble the mast cells that may be demonstrated in the rat's mesentery by similar fixation and staining or by alcohol fixation and staining with methylene blue or toluidine blue. For this reason we consider these metachromatically staining cells to be mast cells.

Recent work[4] suggests that some mast cells may be distinguished by their ability to release adrenaline and noradrenaline when suitably stimulated and may be classified as chromaffin cells. The mast cells of rat sural and caudal nerves do not exhibit the 'chromaffin' reaction as this has recently been defined[5], that is, they do not exhibit a yellow coloration after treatment with Orth's fluid. Subsequent staining of the same sections with methylene blue, however, revealed the normal complement of metachromatically stained cells. At the same time, Orth-fixed suprarenal medulla did show the 'chromaffin' reaction in cells which, when stained with methylene blue, did not exhibit metachromasia.

In injured rat nerves some changes occur in the mast cell population, as compared with normal nerves. In nerves cut 1–8 days previously a higher proportion (statistically significant) of the cells appeared to have shed some or many of their granules into the nearby tissue spaces, although the total number present had not changed. In four nerves injured 8 months previously, however, the number of mast cells present had increased about 4 times; in 5 mm. of rat caudal nerve cut, or crushed and allowed to regenerate, as many as 1,250 were counted, as compared with 250–300 in a similar length of normal nerve.

The function of these endoneurial mast cells is at present obscure. In many peripheral nerves a high content of histamine has been recorded[6], and in other tissues this has usually been related to a high content of mast cells[7]. There is also much evidence to implicate mast cells in the elaboration of connective tissue ground substance and, indirectly, of fibrils, although by means as yet unknown[8]. Thus, while mast cell hyperplasia is marked in conditions of fibroplasia, the latter usually appears first. This observation is consistent with the finding of mast cell hyperplasia only in nerves which have degenerated for a long time, where it may be related to the increase in connective tissue collagen reported by Abercrombie and Johnson[9] in such nerves. Mast cells may play some part in the metabolism of endoneurial connective tissue, aiding the formation of fibrils but unable to initiate the process. Their presence may be relevant to the problem of the origin of this tissue, which is by no means satisfactorily solved[10].

PATHOLOGY

Histochemical Evidence of 5-Hydroxytryptamine in a Dog Mast Cell Tumour

Mast cells of dogs are said not to contain 5-hydroxytryptamine[1–4]. Furthermore, this substance has not been found in neoplasms of these cells in dogs[5]. An instance of a dog mast cell tumour is reported here, however, in which there was histochemical evidence of the presence of 5-hydroxytryptamine.

The tumour removed surgically was a cylindrical teat-like projection from the abdominal surface of a black terrier. The neoplasm measured 3·5 cm. × 1·8 cm. × 1·3 cm. It was of soft texture and grey-white in colour. It had the characteristic histological structure and cytological features of a mast cell neoplasm. The tissue was fixed in acid (*p*H 5·5) formalin and examined histochemically. A toluidine blue stain revealed clusters of large round cells having the characteristic metachromatic granules of mast cells (Fig. 1). The histochemical tests for 5-hydroxytryptamine have been devised to distinguish this substance from other related compounds.

Schmorl's ferric ferricyanide produced a strong reaction, indicating the presence of reducing substances in the granules which had survived formalin denaturation; catechols do not[6].

Black cytoplasmic granules in most of the mast cells of the tumour following Lillie's diazo-safranin reaction indicated the presence of enterochromaffin substance. The identity or close chemical relationship of enterochromaffin substance and 5-hydroxytryptamine is well established. Lillie claims that phenylalanine, tyrosine, tyramine, tryptophan and other tryptamines all fail to produce this reaction with this reagent[6].

Frozen sections of the material fixed in acid formalin were examined by ultra-violet light emitted from a General Electric *AH*6 1,000-watt mercury arc, and filtered through a Corning heat-absorbing blue filter and a Corning ultra-violet-transmitting filter (No. 5840) with maximum transmission at 350 mμ.

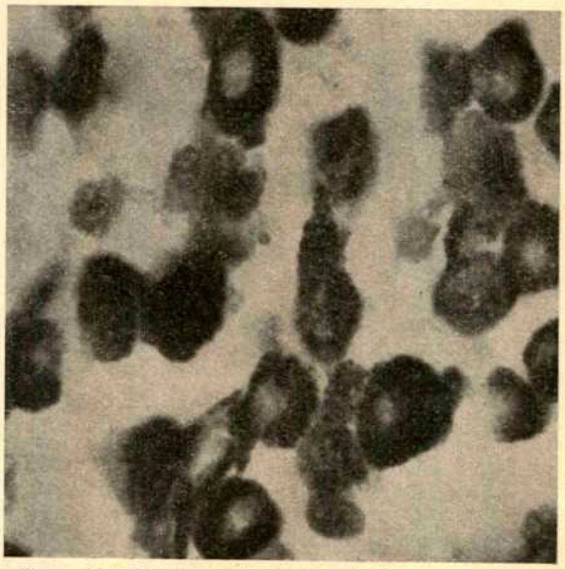

Fig. 1. Mast cells in a frozen section of a dog neoplasm stained with toluidine blue. The cytoplasmic granules which were strongly metachromatic are prominent

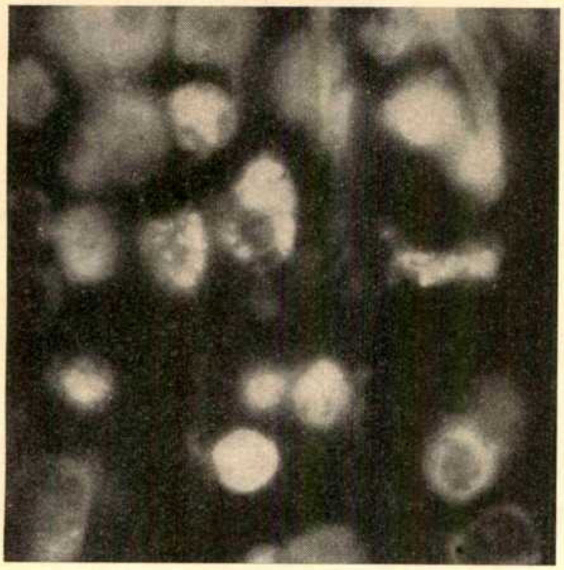

Fig. 2. Bright (orange) fluorescence in granules and in cytoplasm of the dog mast cells treated with Benditt's ninhydrin–acetic acid reaction

A Reichert Zetopan microscope equipped with an ultra-violet-transmitting dark-field condenser was used for the observations. The cytoplasmic granules of most, but not all, of the mast cells exhibited a bright golden-yellow fluorescence. The fluorescence was absent or imperceptible when a mercury arc of lower intensity (Osram 200) was used. Benditt modified Jepson and Stevens's ninhydrin method for paper chromatography[7] so that it can be used histochemically to demonstrate fluorescence of tryptamines[8]. Ninhydrin is sublimed (at 5×10^{-3} mm. mercury at 100–120° C.) on to the section of tissue which is then treated with vapours of acetic acid and acetone and examined with ultra-violet light. The mast cells so treated showed discrete, orange, fluorescent cytoplasmic globules (Fig. 2).

The following is a summary of the histochemical evidence of 5-hydroxytryptamine in the mast cell tumour :

Histochemical procedure	Results
Toluidine blue	Metachromasia of cytoplasmic granules (Fig. 1)
Schmorl's ferric ferricyanide	Strong reaction
Gomori's diazonium reaction	Strong reaction
Lillie's diazo-safranin for enterochromaffin	Strong reaction
Ultra-violet fluorescence	Golden-yellow fluorescent granules
Vapour-phase ninhydrin (for tryptamine derivatives)	Orange fluorescent granules (Fig. 2)
Methenamine–silver	Variable

According to Benditt (ref. 9 and personal communication from Benditt, E. P., to W. G. R), and Barter and Pearse[10], a specific fluorescence is produced by the interaction of acid formalin and 5-hydroxytryptamine. Catechols and resorcinol do not fluoresce like that after formalin treatment. The fluorescence noted in enterochromaffin cells after acid–formalin fixation is concluded to be due to 5-hydroxytryptamine.

This fluorescence along with positive ferric-ferricyanide and diazo-safranin (Lillie) reactions are strong presumptive evidence of the occurrence of 5-hydroxytryptamine in the mast cells of this tumour.

The variable methenamine–silver reaction cannot be equated with 5-hydroxytryptamine production[11] ; therefore, the failure consistently to reduce silver in this case does not indicate its absence.

Histochemical evidence of the presence of 5-hydroxytryptamine in a dog mast cell tumour implies an intraspecies as well as interspecies difference in its distribution in these cells. When induced ultra-violet fluorescence is being studied, the importance of using a high-intensity light source is emphasized.

This work was supported by U.S. Public Health Services research grant C–4521, and a training grant 2–G–207.

Identification of So-called Atypical Macroglobulinæmia as an Atypical Form of β_{2A}-Paraproteinæmia : a New Immunological Entity?

OCCASIONALLY, ultracentrifugation of sera from patients with multiple myeloma yields an abnormal protein fraction with a sedimentation constant of 8–12 *S*. Jahnke and Scholtan[1] referred to such cases as "atypical macroglobulinæmia", because the sedimentation constant of these pathological proteins is smaller than that of the 'true' macroglobulins such as found in Waldenström's macroglobulinæmia.

Little is known as yet about the nature of these proteins. It was pointed out by Putnam[2] that these rapidly sedimentating proteins are exclusively encountered in the case of so-called β-myelomata. They differ from the β_{2M}-macroglobulins in immunological characteristics[3].

In sera from nine patients suffering from multiple myeloma, investigation with the aid of the ultracentrifuge revealed an abnormal protein fraction with a sedimentation constant between 8 and 12. In most cases, this rapidly sedimenting component was visible in the ultracentrifuge diagram as a sharp peak with a narrow base—a picture characteristic of paraproteinæmia.

Sulphydryl reagents did not dissociate these atypical macroglobulins into smaller 6-*S* fragments, a fact which is in contrast with the findings obtained in Waldenström's macroglobulinæmia[4]. Disulphide bridges, therefore, are probably of no importance in the macromolecular structures of the proteins under investigation.

After electrophoresis in agar-gel[5], a pathological protein fraction in the β-globulin or high-speed γ-globulin region was found in all sera (Fig. 1*a*). Two abnormal protein fractions were present in two cases. The quantitatively most important fraction was found in the β-globulin region, while the less pronounced component was localized in the γ_2-globulin area (Table 1). All paraprotein fractions were periodic acid–Schiff-positive, but failed to stain with sudan black.

Two sera (*Be* and *Bu*) were examined by zone electrophoresis on starch. It was found that the paraprotein component of both sera was separated into two fractions, which could be isolated. The chemical and immunological analysis of these fractions is now in progress.

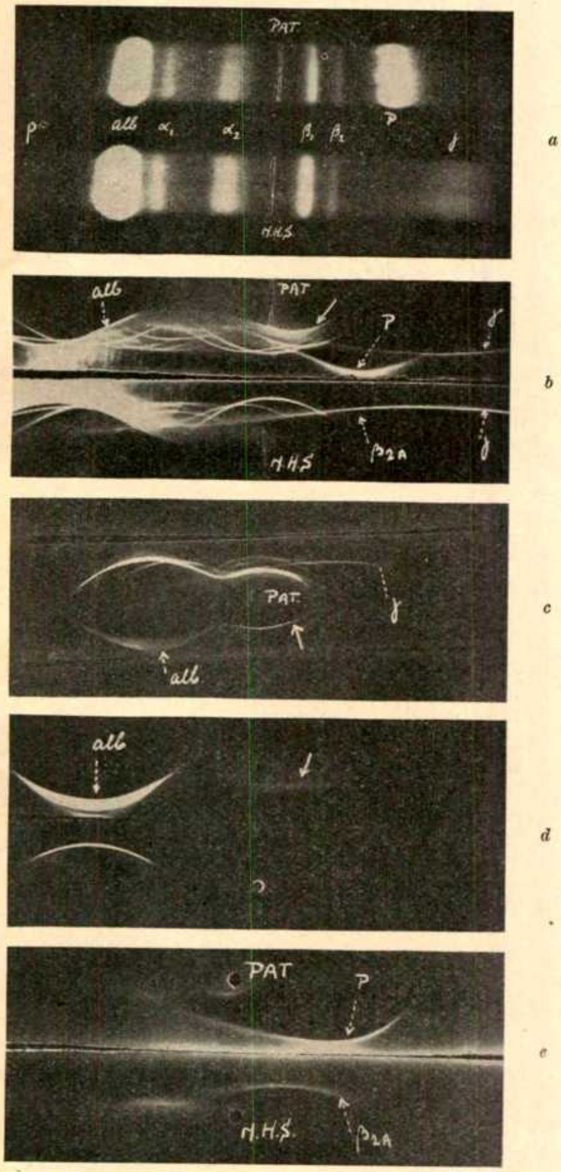

Fig. 1. *a*, Pherograms (agar gel-electrophoresis; barbital buffer *p*H 8·6; 35 V./cm.) obtained on normal human serum (*N.H.S.*) and on the serum of patient *Bu* (*PAT*). Note the paraprotein fraction in the latter serum (*P*). *b*, Immuno-electrophoresis of the serum of patient *Bu* (upper basin) and of normal human serum (lower basin). Note the deformation in the β_{2A}-line (*P*) and the abnormal albumin precipitation line (arrow). The antiserum used was *K*6. *c*, Immuno-electrophoresis of the serum of patient *Ve*. The antisera used were *K*6 (upper basin) and anti-human albumin immune serum (lower basin). *d*, Immuno-electrophoretic analysis of the serum of patient *Be* before (upper basin) and after (lower basin) treatment with cysteine. The antiserum used was anti-human albumin immune serum. Note the disappearance of the albumin line in the β-globulin region. *e*, Immuno-electrophoresis of the serum of patient *Bu* (upper basin) and of normal human serum (lower basin). The antiserum was *K*6, absorbed with umbilical cord serum and normal human serum. It is clearly demonstrated that the paraprotein fraction has β_{2A}-antigenic determinants

Table 1

Patient	m_r	Localization in the pherogram
Be	0·31	Between β_2 and γ-globulin
Bon	—	Dense precipitate behind application groove
Bo	0·35	Just behind the β_2-globulin
Bu	0·28	In the fast γ-globulin region
De	0·29	In the fast γ-globulin region
Le	0·29	In the fast γ-globulin region
PB (main fraction)	0·30	Between β_2- and γ-globulin
(small fraction)	0·12	In the slow γ-globulin region
Pu (main fraction)	0·39	On the β_2-globulin fraction
(small fraction)	0·27	In the fast γ-globulin region
Ve	0·41	On the β_2-globulin fraction
β_2-globulin in normal human serum	0·42	

Relative mobilities m_r of the paraprotein fractions in the serum of 9 patients with 'atypical macroglobulinæmia'. Agar-gel electrophoresis. Difco 'Nobel Agar'. Barbital buffer *p*H 8·6; voltage 35 V./cm. For technical details see ref. 5.

For the purpose of more precise characterization of the paraprotein fractions in the sera from our patients, these sera were submitted to immuno-electrophoretic examination. With the aid of a horse antihuman immune serum (Institut Pasteur, Paris), we obtained results such as those seen in the case of β_{2A}-myelomata[6,7]. The β_{2A}-line in the diagrams was considerably accentuated and displaced towards the antiserum reservoir (Fig. 1*b*). The β_{2M}-line was as a rule lacking. The γ-line sometimes showed shortening towards the anode side. The same results were found with a rabbit immune serum (*K*6) against the serum of one of our patients (*Be*). In the β-globulin region there was in the immuno-electrophoretic examination of all sera a short but heavy precipitation line, situated near the antigen-cup. This abnormal line, which could not be detected in immuno-electrophoretic analysis of normal human serum, shows a reaction of identity with the albumin line (Fig. 1*b*—arrow). This was clearly demonstrated by immuno-electrophoresis of the patients' sera with a rabbit anti-human albumin immune serum (Behringwerke) (Fig. 1*c*).

The abnormal protein fraction in the β-globulin region is probably a complex of albumin with a yet unknown protein. This complex could be dissociated by treatment with cysteine (Fig. 1*d*).

These findings have only been reported before by Heremans[8]. In some of the cases of β_{2A}-myeloma, investigated by him, this albumin complex in the β-globulin region was found. It is likely that these cases represent β_{2A}-paraproteinæmia with a rapidly sedimentating protein component.

Besides this abnormal albumin precipitation line there was sometimes additional abnormal precipitation lines in the β-globulin region. By immuno-electrophoresis with a rabbit anti-human γ-globulin immune serum, it was demonstrated that these lines have a γ-globulin antigenic structure.

All sera were examined by immuno-electrophoresis, with a specific rabbit anti-β_{2A}-globulin immune serum (Behringwerke) as anti-serum. In all cases, a precipitation line was visible which corresponded with the line *P* found with horse antihuman immune serum; this proved that the paraproteins under investigation did in fact possess β_{2A}-antigenic determinants.

A rabbit anti-serum (*K*6) was prepared against the serum from patient *Be*. This anti-*Be* immune serum was absorbed with umbilical cord serum and normal human serum. After absorption, this antiserum contained only antibodies against β_2A-globulins because—both in immuno-electrophoresis with normal human serum and with the sera from our patients—it reacted by forming the β_2A-line (Fig. 1*e*). Cross-reactions were excluded with certainty because, using Ouchterlony's agar diffusion technique, reactions of identity were obtained between the sera from our patients, both with rabbit anti-β_2A-globulin immune serum and with absorbed rabbit anti-*Be* immune serum.

A β_2A-paraproteinæmia with the presence of an abnormal albumin component in the β-globulin region was found to exist in the sera from nine multiple myeloma patients examined, containing an abnormally rapid sedimenting ($s_{20} = 8 - 12\ S$) protein fraction. If this is to be found in all cases of so-called atypical macroglobulinæmia, then it would be advisable to abandon the designation 'atypical macroglobulinæmia' (which is incorrect because it suggests a non-existing correlation with Waldenström's macroglobulinæmia[9-11]) in favour of the term 'atypical β_2A-myeloma'.

We wish to thank Dr. P. Burtin of the Institut Pasteur, Paris, for analysing two sera, and Dr. G. Schwick of the Behringwerke for supplying rabbit anti-β_2A-globulin immune serum.

Fibrosarcoma in a Rabbit following β-Irradiation of the Skin

THIS communication describes the gross and histological appearance of a fibrosarcoma which occurred four years after exposing an area of rabbit skin to 16,000 rads from a phosphorus-32 plaque. The only previous observation of skin tumours in rabbits resulting from radiation exposure is contained in a recent communication by Sissons and Vaughan[1]. These workers described squamous cell carcinomas in the external auditory meatus of rabbits injected with strontium-90 at an early age. The available literature indicates a low natural incidence of tumours in rabbits[2,3].

Four years ago, we began work in this Laboratory to determine the variation in the skin reaction of rabbits, pigs and sheep after acute exposure of doses of 2,000, 8,000 and 16,000 rads of β-irradiation. Six rabbits were exposed to either strontium-90 or phosphorus-32 plaques at two sites per animal with four sites exposed to each of the dosage-levels indicated. The radiation intensity was in the range of 5,000–8,000 rads/hr. The experimental animals are being kept for their life-span. The clinical appearance of the acute and chronic reactions is being reported separately (L. A. G. and L. K. B., in preparation).

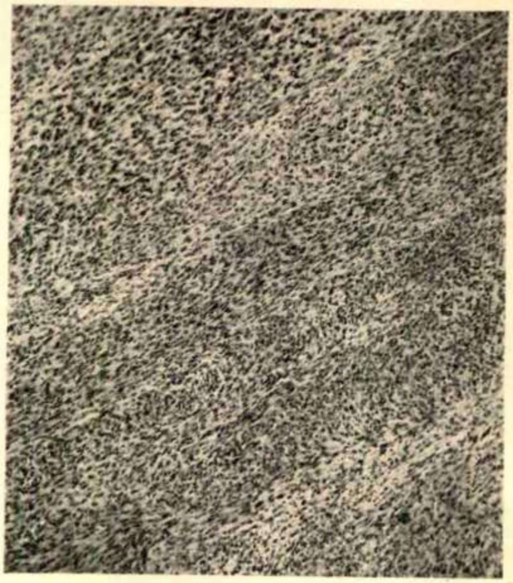

Fig. 1. Bundles of connective tissue fibres in well-differentiated areas of primary skin tumour (× 65)

The primary tumour occurred at the site of the original β-irradiation exposure. The tumour formed a moderately firm, spherical mass, measuring 6 cm. in diameter and raised to a height of 5 cm. above the body surface. The mass was located in the loose connective tissue between the body wall and the skin, which had become necrotic at the irradiation site over the tumour. Metastases were observed

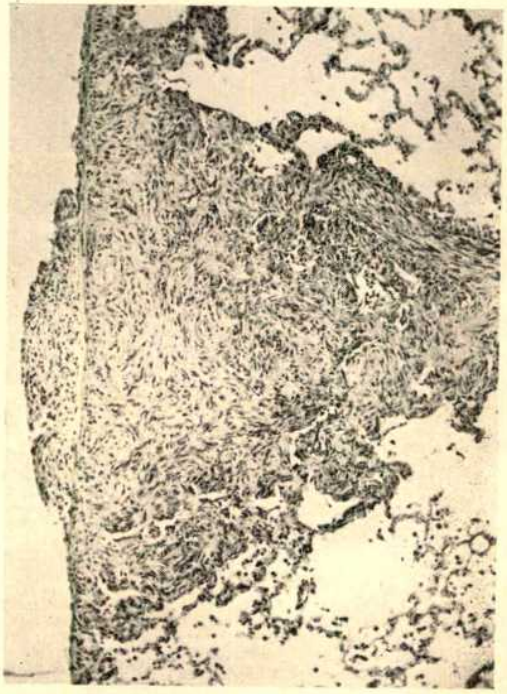

Fig. 2. Pulmonary metastasis. (× 65)

grossly in the lung. The lesions in the lungs consisted of several small (1–2 mm.), round, white nodules on the surface of the right and left diaphragmatic lobes.

The basic histological pattern of the tumour consisted of interlacing bundles of moderately cellular fibrous connective tissue (Fig. 1). The well-differentiated areas showed few mitotic figures. A network of fibres between the individual cells was demonstrated in the differentiated areas with the Laidlaw stain. Other regions of the tumour disclosed moderate pleomorphism with rounding of the nuclei and diminished formation of fibres. Mitoses were somewhat more frequent in such areas, which also contained foci of œdema and necrosis. The pulmonary metastases revealed a relatively loose pattern of fibroblastic cells (Fig. 2). The small metastases were often necrotic except for a narrow peripheral rim of viable tissue. The tumour was diagnosed pathologically as a fibrosarcoma.

BIOLOGY

Promotion of Leaf Growth by Short Days in the Short-Day Plant *Chenopodium amaranticolor*

PAST investigations into the relationship between length of day, flowering and leaf-growth have failed to explain the complex interactions between them. In most, if not all, plants the development of flower buds is associated with a reduction in leaf-growth and eventually leads to bract formation[1], and Bünning and Konder[2] have shown that leaf growth in plants maintained in a vegetative state is less for inductive than non-inductive conditions in the short- and long-day plants they studied. On the other hand some results obtained by Schwabe[3] seem on re-examination to indicate a promotion of leaf-growth by inductive conditions in *Xanthium*.

Recent work by me (the results of which will be published elsewhere) has shown that conditions leading to flowering in *Chenopodium amaranticolor* initially also promote vegetative growth. Plants which were grown from germination in 16-hr. photoperiods for 26 days were then induced to flower by transfer to various numbers of 8-hr. days. As an immediate result of such transfer the rates of leaf and axillary bud initiation at the apex increased considerably. Four days after the start of short-day treatment the daily rate of leaf initiation had increased to 3·50 from a long-day value of 0·46 and vegetative axillary bud initiation had increased from 0·46 to 2·05 a day. At the same time the rate of growth of all immature leaves was stimulated by exposure to short days, even though it was strongly inhibited afterwards in induced plants. The growth of the leaf at node 7, which reached maturity before the inhibition became dominant, is shown in Fig. 1.

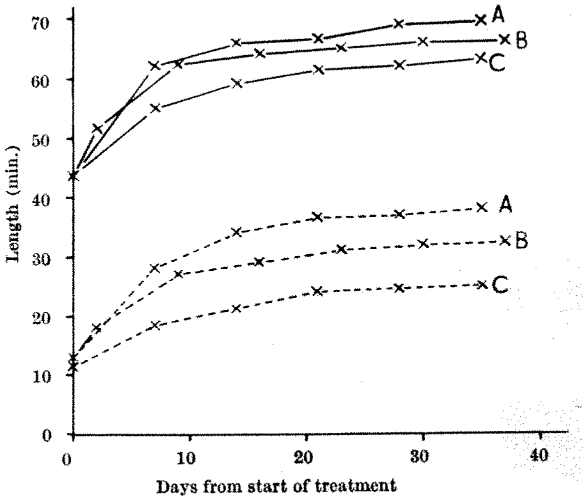

Fig. 1. Effect of inductive treatment on petiole (- - -) and lamina (——) growth of leaf 7 (8 plants per treatment). Plants were grown in long days and then received: *A*, continuous short days; *B*, two short days followed by long days; *C*, long days (control)

To test the closeness of this relationship between leaf-growth and flowering in *C. amaranticolor*, a comparison was made of the effects of short days with and without interrupted dark periods. Plants were grown in a glasshouse in continuous light (consisting of natural daylight in March–April at Palmerston North supplemented by light from 200-W. 'Sieray' mercury vapour lamps ballasted with a tungsten filament which gave an intensity of approximately 500 ft.-candles at the plant apices) for the seven weeks between germination and the start of inductive treatment. They were then divided into four groups of eight as shown in Table 1, 16 receiving 8-hr. photoperiods (–*LB*) and the other 16 receiving 7-hr. photoperiods, with 16-hr. dark periods interrupted at the mid-point by a 1-hr. light break (+*LB*) at an intensity of approximately 3,500 ft.-candles. The total amount of light received daily by each group was the same. Buds were excised from the axils of all leaves longer than 16 mm. immediately prior to short-day treatment. In 16 plants (8 + *LB*, 8 – *LB*) all apical tissue above the youngest leaf longer than 16 mm. was removed and in the other 16 the apical tissue was retained. The effect of these treatments on the growth of the youngest leaf longer than 16 mm. is shown in the table; both with and without apical tissue the growth of the – *LB* groups (flowering) was significantly higher than that of the + *LB* groups (non-flowering). It thus seems very possible that a direct relationship exists between the promotion of leaf growth and the onset of flowering. The fact that a similar relationship occurs in both the presence and absence of apices indicates that the

Table 1. PERCENTAGE INCREASE IN LEAF LENGTH AFTER SIX SHORT DAYS WITH AND WITHOUT INTERRUPTED DARK PERIODS

	– *LB*	+ *LB*	*P* (from *t* test)
+ apex	69·14	53·75	0·019
– apex	77·40	61·25	0·044

growth stimulus is related to some step preceding the initiation of flower primordia and does not emanate from them.

Investigations to determine the universality of the promotion of leaf-growth which occurs in inductive conditions in *Chenopodium* and *Xanthium*[3] are in progress. Meanwhile the situation prevailing at the apex, where the transition to flowering is clearly associated with an increased growth-rate, indicates that such a tendency to increased leaf growth throughout the plant probably occurs very widely concomitant with the onset of flowering. Once flower primordia are formed, however, they exert a strong inhibitory influence on leaf growth which quickly suppresses any initial stimulation which might have been present.

Estimation of Oil in Safflower Seed

WEIGHT per measured bushel is a widely used index of physical quality of grain[1]. In applying this measure of quality to varieties of safflower (*Carthamus tinctorius*) grown on dry land in southern Alberta during 1957–60, there was a correlation of $r = -0.68$ ($P < 0.01$) between oil percentage and bushel weight. The weight per measured bushel of varieties varied from 36·5 to 49·5 lb., whereas the oil content varied from 37·9 to 25·0 per cent, respectively. Since this relationship is contrary to that generally expected, some of the physical and chemical properties of the seed were investigated. Seed from fourteen varieties grown at three locations were used for this purpose.

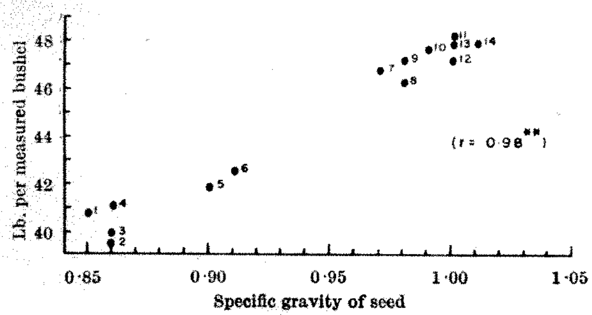

Fig. 1. The interrelationship between oil percentage, weight per measured bushel, and specific gravity of the seed of 14 safflower varieties. $P < 0.01$

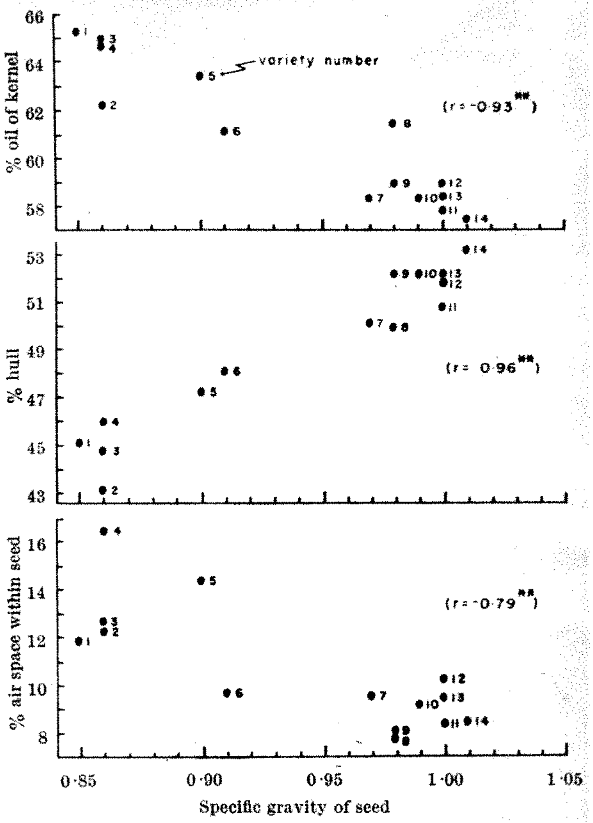

Fig. 2. The interrelationship between specific gravity of safflower seed, air space inside the seed, oil percentage of kernels, and hull percentage. $P < 0.01$

The specific gravity of the seed was determined for each variety on the basis of four 100-seed samples from each location. The varietal means for three locations for oil percentage, specific gravity, and bushel weight are shown in Fig. 1. It is evident from these results (Fig. 1) that varieties with low oil percentages could be eliminated on the basis of either their high bushel weight or high specific gravity. This relationship between oil percentage and specific gravity of seed is sufficiently close to be of practical value in evaluating safflower lines for their oil content. The weight per measured bushel is easily obtained where a substantial quantity of seed is available, but the specific gravity index has the advantage of being equally applicable to both small and large quantities of seed. Furthermore, it can be used to advantage in screening segregating populations.

Since low specific gravity of seed is associated with high oil percentage, additional analyses were carried out to determine some of the factors that might contribute to this relationship. The percentage air space inside the seed was calculated for each variety by determining the difference in volume between whole and split seed. The hull with adhering seed coat was separated from the kernel to calculate the percentage hull of the seed and percentage oil in the kernel. Varietal means of three locations for these determinations are given in Fig. 2. The percentage air space inside the seed and oil percentage of the kernel decreased with increasing specific gravity whereas the hull percentage increased. The association between specific gravity of seed and hull percentage was investigated further by determining the specific gravity of the hulls. Although the specific gravity of the hull was found to vary with varieties, it was always greater than that of the whole seed. This explains the close relationship between specific gravity of seed and percentage hull. The high specific gravity of hull and the factors illustrated in Fig. 2 clarify the relationship between high oil percentage and low specific gravity of safflower seeds.

These results will be reported in greater detail elsewhere.

Potato Root Eelworm in the Canary Islands

The European and Mediterranean Plant Protection Organisation annual reports 1953–1959, which survey the incidence of the potato root eelworm, *Heterodera rostochiensis*, record the occurrence of this major pest of potatoes in all member countries except Italy, Yugoslavia, Rumania, Turkey, Cyprus, Malta, Libya and Tunisia.

On December 27, 1960, in company with Sr. Iuan Valladares Barbuxano, Ingeniero Agronomo de la Jefatura Agronomica, I discovered the existence of *H. rostochiensis* in potato fields at La Victoria de Acentejo and in other districts in the north of Tenerife, Canary Islands. At latitude 28° 25′ N., this would appear to be the most southerly occurrence as yet recorded in the geographical distribution of *H. rostochiensis* in the Old World.

A Technique for Destruction of the Pineal Body using Yttrium-90 Spheres

Excision of the pineal body, first described by Exner and Boerse[1], has been frequently used in the study of pineal function and has been performed in various groups of animals[2]. Thermocauterization and stereotaxic ablation have also been employed. The operative mortality with the latter methods has been quite high due to hæmorrhage from adjacent blood vessels[2].

A technique using yttrium-90 spheres for radiological destruction of the pituitary gland was recently introduced[3]. The same source of radiation was used in the present work. The yttrium spheres were manufactured as described by Ginell and Simon[4] and by Ginell and Doering[5]. The activity of the spheres following activation in an atomic reactor was calculated as described by Notter and by Notter *et al.*[3,6]. A 2–3 cm. mid-line incision was made over the occipital region of fifteen rats following anæsthesia which was maintained with ether. A hole about 1·5 cm. in diameter was drilled exactly above the site of the pineal body. The position of the hole had been calculated in relation to the visible sutures between the parietalia and the occipital bone (checked by X-ray photograph, Fig. 1). Three or four spheres were inserted on and around the pineal body. Damage to the venous sinuses, which overlie the gland, could not be avoided but the bleeding induced was easily stopped.

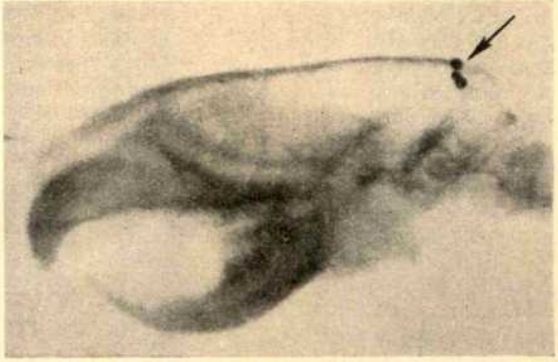

Fig. 1. X-ray photograph of the skull showing the site of the spheres. (× 3)

Four experimental animals died within 2–4 days following the operation, whereas the remaining survived and were killed on the 15th, 20th and 35th day after the operation. The brains and endocrine organs were then fixed for future examination. A preliminary examination of the irradiated tissue of the pineal brain region showed complete necrosis of the pineal body in eight cases. The radiation dose needed to obtain complete necrosis, provided that the spheres were placed correctly in relation to the pineal body, was calculated as approximately 100,000–150,000 rads, thus causing necrosis at the distance of 1·5–2 mm. from the periphery of the spheres.

No appreciable radiation damage was found in the cortex of the brain adjacent to the pineal body,

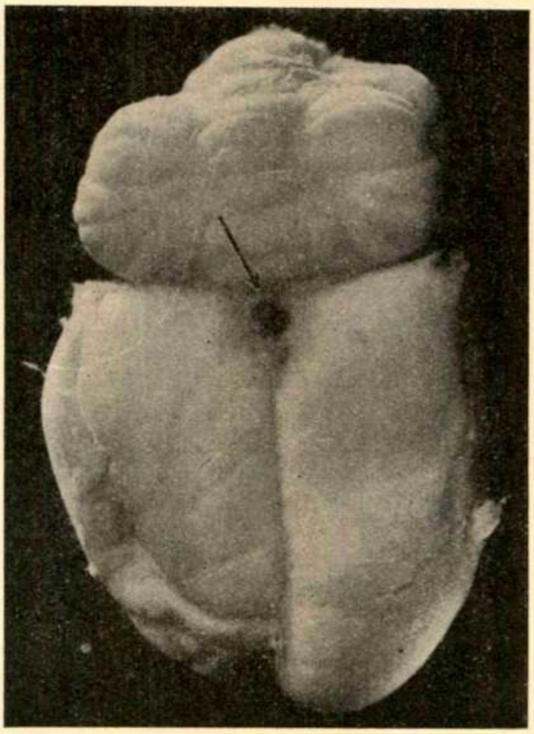

Fig. 2. Dorsal view of the rat brain indicating the position of one of the yttrium spheres. (× 3)

except for two cases in which the spheres had been placed incorrectly in relation to the pineal body. Partial necrosis of the pineal body (50–80 per cent) was obtained in a few cases in which the position of the spheres apparently had not been optimal in relation to the pineal body. However, since a total of eight cases out of 11 surviving cases were obtained with a complete destruction of the pineal body, it was concluded that the method described must be considered as a suitable means for localized destruction of the pineal body, and other small tissue areas as well.

This work was supported in part by the Tullberg Fund, University of Uppsala. We acknowledge the advice of Prof. M. D. Altschule, McLean's Hospital, Waverley, Mass., in preparing the manuscript.

A Biennial Copepod from Lake Hazen, Ellesmere Island

Several species of copepods in the Arctic are known to have annual life-cycles in the sea[1] and freshwater[2], and macroplanktonic Crustacea of northern seas may not breed until two years old[3]. So far as I am aware, no copepod has been described with a life-cycle greater than one year, and the extreme response of *Cyclops scutifer* in Lake Hazen to conditions of low temperature and limited food seems worth recording.

Lake Hazen (lat. 81° 45′ N., long. 71° 00′ W.) is the largest lake of the Queen Elizabeth Islands of high-arctic Canada. It is glacier-fed, cold and deep, and is not always entirely free from ice in summer. Primary productivity is very low, and the fauna is small in species and individuals.

The zooplankton was sampled regularly between mid-June and mid-August. The proportions of naupliar and copepodite stages at one offshore station on four successive dates are given in Fig. 1. The proportions of the stages were very similar in plankton collections from other parts of the Lake. The conspicuous and persistent bimodality of the population throughout the short sampling period can only be the result of a basically biennial life-history. A very few adults were taken in a surface haul on August 11, the last date of sampling, but presumably most copepodites do not reach adult-hood and breed until the autumn months. The products of this breeding pass the winter as nauplii and just begin to enter the copepodite stages by the following summer. The possibility of slight exchange between the generations is suggested by the stage I copepodites of June 18 and the stage II copepodites of August 11.

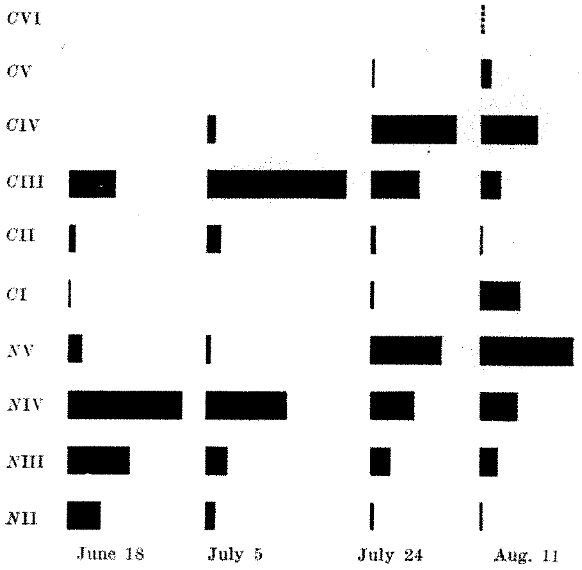

Fig. 1. The proportions of the stages of nauplii and copepodites of *Cyclops scutifer* in vertical plankton hauls from 32 m. at the same station on four successive dates. No adults (*CVI*) were taken in the vertical haul of August 11, but a few were taken in a nearby surface collection on that date

I am indebted to Dr. Edward B. Reed, Colorado State University, for finding the half-dozen adult copepods in the entire collection and identifying the species as *Cyclops scutifer* Sars. Field work was carried out in summer 1958 on the Canadian International Geophysical Year expedition to Ellesmere Island, organized by the Defence Research Board of Canada. Collections were analysed at the Bingham Oceanographic Laboratory, Yale University. A more complete account of the aquatic biology of Lake Hazen is in preparation.

BACTERIOLOGY

Biosynthesis of Acetoin by *Leuconostoc citrovorum*

It has been shown[1] that in most bacterial cells acetoin is formed by the condensation of pyruvate and activated acetaldehyde. The findings of Beckhorn[2], De Man[3] and Mizuno and Jezeski[4] leave no doubt that in the heterofermentative genus *Leuconostoc* the synthesis occurs via acetolactate. It is still uncertain, however, if acetoin is formed from sugar and, if so, out of which part of the carbon chain of the sugar. Preliminary experiments showed that washed cell suspensions of *Leuconostoc citrovorum* ATCC 8082 do not form acetoin during glucose fermentation in a phosphate buffer. On the other hand, a large amount of acetoin is produced from pyruvate. When pyruvate and glucose are added simultaneously, the synthesis of acetoin is inhibited.

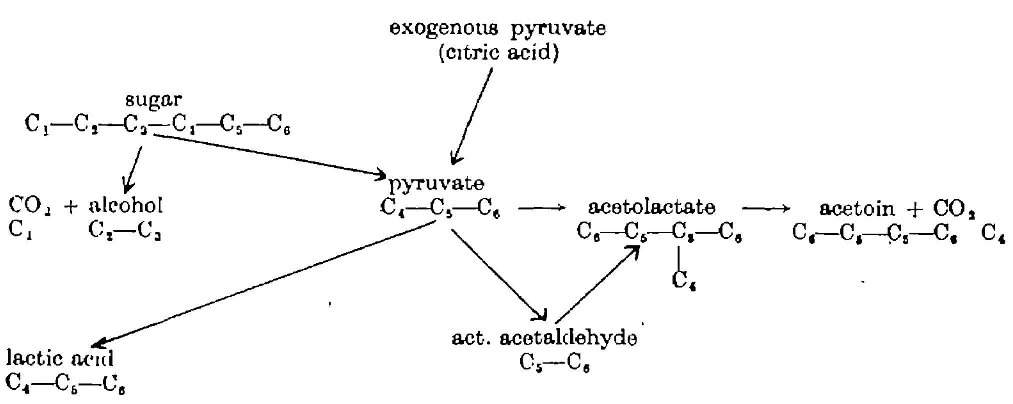

Fig. 1. Scheme of acetoin synthesis by *Leuconostoc citrovorum*

Only at the end of the fermentation, when the glucose concentration becomes so low that the production of carbon dioxide decreases, does the synthesis of acetoin begin. In the presence of a favourable H-donator (glucose) the pyruvate in the cell is presumably reduced so quickly to lactic acid that the condensation of pyruvate to acetolactate does not occur.

In order to check if any part of the carbon skeleton of glucose is actually used for the synthesis of acetoin, glucose-1-^{14}C, 2-^{14}C and 6-^{14}C were fermented with aliquot parts of a *Leuconostoc* suspension in the presence of a 5-fold excess of pyruvate. After the drop in carbon dioxide production the radioactivity in the acetoin formed was determined. As shown in Table 1, radioactive acetoin is produced only when glucose-6-^{14}C is employed. The specific activity was eight times less than that of the corresponding carbon atoms in the glucose. From this one may conclude that only one-eighth of the synthesized acetoin results from the carbon chain of glucose, the rest from pyruvate. In addition it is seen from Table 1 that only the lower part of glucose can be used for the synthesis of acetoin, and not the C_{2+3} moiety, which appears as alcohol during fermentation. According to the results of Heath *et al.*[5], C_{2+3} first yields acetylphosphate, which is probably reduced further to alcohol via acetaldehyde. Obviously the acetaldehyde cannot be activated and is not used for the synthesis of acetoin. Thus the scheme presented in Fig. 1 may be considered as established for the formation of acetoin in the heterofermentative genus *Leuconostoc*.

In contrast to these findings, Andersen[6] reported recently that *Leuconostoc citrovorum* ATCC 8081 may produce radioactive acetoin from glucose-1-^{14}C as well as from glucose-6-^{14}C, thus behaving like the homofermentative *Str. diacetilactis*. This result may be explained by the observation of Felton and Niven[7] that the mentioned strain ATCC 8081 is not *Leuconostoc citrovorum* but the homofermentative *Pedicoccus cerevisiae*. To demonstrate clearly that our strain represents a heterofermentative *Leuconostoc*, the radioactivity in the fermentation products of spot-labelled glucose was determined. The result obtained is identical with that of Gibbs *et al.*[8]. A more detailed account will be published in *Zentralbl. f. Bakt.*

Table 1. Specific Activity of Acetoin after Fermentation of Labelled Glucose in the Presence of Unlabelled Pyruvate

	Barium carbonate (mgm.)	Specific activity (mμc./m*M* acetoin)
Glucose-1-^{14}C	10·72	0·64
Glucose-2-^{14}C	11·78	0·77
Glucose-6-^{14}C	10·57	32·30

Pyruvate, 500 μ*M*; glucose, 100 μ*M*; manganese chloride, 8 mgm.; calcium chloride, 8 mgm.; phosphate buffer, 0·1 *N*; *p*H 4·8. Total volume, 20 ml.; glucose-1-^{14}C, 89·2 mμc./m*M*; glucose-2-^{14}C, 77·3 mμc./m*M*; glucose-6-^{14}C, 81·0 mμc./m*M*.

Chloramphenicol, a Simultaneous Carbon and Nitrogen Source for a *Streptomyces* sp. from Egyptian Soil

In work concerning the decomposition of antibiotics in soil and micro-organisms capable of this process, a chloramphenicol solution (250 μgm. chloramphenicol/gm. soil) was percolated through 25-gm. sieved fresh garden soil, *p*H 7·5, in an apparatus similar to that described by Lees and Quastel[1]. The chloramphenicol was applied in three doses; the first dissolved in 50 ml. sterile distilled water and the others in 5 ml. added to the percolate in the reservoir. The antibiotic was bioassayed daily against *Bacillus subtilis*. The first dose disappeared after 11 days and the second and third after 3 days.

Isolation of the micro-organisms involved in the decomposition of chloramphenicol was then carried out by plating the enriched soil in a medium containing the antibiotic as the sole organic carbon source. The medium (ammonium nitrate chloramphenicol medium) contained, in gm. per 100 ml., crystalline magnesium sulphate, 0·5; crystalline ferrous sulphate, 0·003; calcium chloride, 0·005; potassium dihydrogen phosphate, 0·1; dipotassium hydrogen phosphate, 0·25; ammonium nitrate, 0·05; agar, 1·3—adjusted to *p*H 7·0–7·2, dispensed in 100 ml. quantities and autoclaved at 15 lb. for 15 min. Before use, the medium was melted, cooled to 50° C. and chloramphenicol (100 μgm./ml.) added. Plates were incubated at 30° C. for 15 days. Only one type of organism appeared on the plates of the highest dilution (10^{-5}), a *Streptomyces* producing greyish-white thin mycelium and chains of chalky white rod-shaped conidia (1·6 × 0·8μ in stained preparations) borne on long open-spiral conidiophores (section *Spira* in the classification of Pridham, Hesseltine and Benedict[2]). Its cultural characteristics on the media proposed by Waksman[3] were: mycelium greyish-white on Czapek's and starch agar and nutrient gelatin, orange on glucose asparagine, glycerol asparagine and yeast glucose agar media, and lemon-yellow on nutrient agar. Chalky white conidia were produced on all the media except on nutrient gelatin where the growth was markedly poor. Pigmentation of the mycelium appeared to be connected with the heaviness of growth; on media showing non-pigmented mycelia the growth was poorer than that produced on media that revealed pigmentation. Growth in liquid media was restricted to a thin unpigmented pellicle consisting of more or less separate colonies which acquired a chalky white surface when conidia were formed. None of the media tested induced the formation of diffusible pigments. Glucose, saccharose, lactose and mannitol were not utilized. There was no hydrolysis of starch, liquefaction of gelatin, digestion of casein or cellulose, production of ammonia from peptone or reduction of nitrate. Litmus milk turned alkaline after 15 days. Growth took place at 18° and 30° but not at 55° C. The organism resisted pasteurization in glucose broth at 60° C. for 30 min. It had no antagonistic properties when tested against *Staphylococcus aureus*, *Bacillus subtilis*, *Escherichia coli* and *Mycobacterium phlei*.

Repeated sub-culture (6 times) in the ammonium nitrate chloramphenicol liquid medium, using straight wire inoculation, always resulted in growth accompanied by the inactivation of the antibiotic, that is, the organism is capable of utilizing chloramphenicol as the sole source of carbon. On sub-culturing in the same manner (6 times) in the liquid medium without ammonium nitrate (chloramphenicol medium) growth and inactivation of the antibiotic again occurred, that is, the organism is capable of utilizing chloramphenicol also as the sole source of nitrogen. This property was confirmed when the growth in the chloramphenicol medium was centrifuged, twice washed with sterile distilled water and used for inoculating fresh media (Table 1). Repeated sub-culturing decreased the inactivation period and improved growth. Inoculation of the liquid medium without chloramphenicol failed to produce visible growth after periods of incubation up to one month.

Table 1. DISAPPEARANCE OF CHLORAMPHENICOL ON REPEATED SUB-CULTURING WITH WASHED *Streptomyces*, INCUBATION AT 30° C.

	100 μgm./ml.*		250 μgm./ml.*	
	Inactivation period (days)	Visible growth†	Inactivation period (days)	Visible growth†
First sub-culture	7	+	20	+
Second ,,	8	++	7	++
Third ,,	3	++	5	++
Fourth ,,	—	—	2	+++

* In non-inoculated controls the variation in diameter of inhibition zones did not exceed ± 0·5 mm. in 20 days incubation.

† Seven days growth on glucose broth ++++.

The ability of the organism to grow in increasing concentrations of chloramphenicol as sole carbon and nitrogen source was tested by inoculating 100 ml. quantities of medium containing 100, 250, 350, 400, 500, 550, 600 and 1,000 μgm. chloramphenicol/ml. with a loopful of 7-day culture in chloramphenicol liquid medium (100 μgm./ml.). Growth of the organism and inactivation of the antibiotic took place in all concentrations up to 600 μgm./ml., where the antibiotic completely disappeared after 13 days. No growth or reduction in activity could be detected within one month in the medium containing 1,000 μgm./ml.

Finally, the purity of the *l*-chloramphenicol used (Kemicetine, Carlo Erba) was verified by the determination of its melting point, carbon, nitrogen, hydrogen and chloride contents and by checking the weight in the capsules supplied.

Work is in progress to elucidate the mechanism of the decomposition of chloramphenicol by the isolate.

We wish to express our thanks to Dr. T. Gibson of the School of Agriculture, Edinburgh, for constructive criticism.

PSYCHOLOGY

An Unexpected Effect of Attention in Peripheral Vision

THE phenomenon described here suggests an unexpected effect of attention in peripheral vision.

Arrange a number of small objects such as keys, coins, etc., on a table and fixate a point among them from some convenient distance, say 3 ft. Maintaining fixation of the point selected, attend to one of the objects and try to see or describe it in detail.

A number of people including experienced psychologists and physiologists have carried out this procedure and have reported what I had previously found, namely, that the object selected for attention becomes hazy and may even disappear. The effect may persist for seconds at a time or it may be fleeting or fluctuating; but other objects in the field remain steadily visible meantime.

It is well known that the whole visual field may disappear when it is 'stabilized', and some people report that this occurs with steady fixation.

The blurring or disappearance of small regions selected for deliberate attention is, however, a different matter and suggests some form of central interference.

Much remains to be done in determining limiting conditions for the occurrence of the phenomenon and in discovering whether it is affected by training and practice. It is in any event a striking example of attention being associated with a loss rather than a gain in clarity.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, March 6

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Mr. Stanislaw Leszczycki (Geographical Institute of the Polish Academy of Sciences): "The Economic Regions of Poland".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS AND COMMUNICATIONS SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. E. D. R. Shearman: "An Investigation on the Usefulness of Back-Scatter Sounding in the Operation of H.F. Broadcasting Services".

SOCIETY OF ENGINEERS (at the GEOLOGICAL SOCIETY, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. H. Kaylor. "Some Aspects of Pre-stressed Concrete".

UNIVERSITY OF LONDON (at Bedford College, Inner Circle, Regent's Park, London, N.W.1), at 5.30 p.m.—Prof. E. Wegmann (Neuchâtel): "Some Aspects of the Geology of the Basements".*

UNIVERSITY OF LONDON (in the Eugenics Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.45 p.m.—Prof. Harald Cramér (Sweden) · "Some Recent Results in the Theory and Applications of Stochastic Processes".* (Further lectures on March 10 and 13.)

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. M. J. Langford: "Photography in Industry and Commerce" (Cantor Lecture).

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. A. Dahlén (Sweden): "Chemical Industry in Sweden".

SOCIETY FOR VISITING SCIENTISTS (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion Meeting on "Scientific Methods in Archæology". Chairman. Dr. E. T. Hall. Speakers: Dr. C. M. Lerici, Mr. M. J. Aitken and Dr. E. H. Willis.

Monday, March 6—Thursday, March 9

OIL AND COLOUR CHEMISTS' ASSOCIATION (in the Royal Horticultural Society's New Hall, Westminster, London, S.W.1)—Thirteenth Technical Exhibition.*

Tuesday, March 7

INSTITUTION OF CHEMICAL ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 4 p.m.—Papers on: "Fluidization".

UNIVERSITY OF LONDON (at the London School of Economics and Political Science, Houghton Street, London, W.C.2), at 5 p.m.—Prof. Eric Voegelin: "World Empire and the Unity of Mankind" (Stevenson Memorial Lecture).*

ROYAL SOCIETY OF ARTS, COMMONWEALTH SECTION (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Sir John Macpherson, G.C.M.G. "Sovereign Nigeria".

INSTITUTION OF ELECTRICAL ENGINEERS, MEASUREMENT AND CONTROL SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. A. V. Hemingway and Mr. R. L. Dressler: : "The Automatic Control of Machines for Assembling Mechanical Components".

UNIVERSITY OF LONDON (at Bedford College, Inner Circle, Regent's Park, London, N.W.1), at 5.30 p.m.—Prof. E. Wegmann (Neuchâtel): "The Folded Chain of the Jura Mountains".*

UNIVERSITY OF LONDON (at Imperial College of Science and Technology, Prince Consort Road, London, S.W.7), at 5.30 p.m.—Dr. C. G. Wynne: "The Correction of Aberration in Optical Systems".

UNIVERSITY OF LONDON (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. H. Lundegårdh (Sweden). "Electron Transport Mechanisms in Plant Cells".* (Further lecture on March 8.)

UNIVERSITY OF LONDON (at the School of Pharmacy, 29–39 Brunswick Square, London, W.C.1), at 5.30 p.m.—Prof. H. W. Mossman (University of Wisconsin): "Glandular Tissues of the Mammalian Ovary".*

UNIVERSITY OF LONDON (in the Gustave Tuck Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Mr. D. T. Swift-Hook: "Magnetohydrodynamic Generation".* (Third of five lectures on "Generation of Electricity without the use of Rotating Machinery".)

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at Hatfield Technical College, Roe Green, Hatfield, Herts), at 7.30 p.m.—Mr. D. Hurden: "Some Chemical Problems of Space Flight".

Wednesday, March 8

ZOOLOGICAL SOCIETY OF LONDON (in the Meeting Room of the Zoological Society, Regent's Park, London, N.W.1), at 10.30 a.m.—Symposium on "Aspects of Disease Transmission by Ticks".

INSTITUTION OF MECHANICAL ENGINEERS, INTERNAL COMBUSTION ENGINE GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 3 p.m.—Meeting on "The Mechanics of the Formation and Adhesion of Deposits Arising from the Combustion of Liquid Fuel".

PALÆONTOLOGICAL ASSOCIATION (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Annual General Meeting. Prof. T. M. Harris: "The Fossil Cycads" (Fourth Annual Address).

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. K. Kramer (University of Göttingen): "Renal Blood Flow in Relation to the Counter Current System".*

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Sir Andrew McCance, F.R.S.: "The Steel Industry To-day and To-morrow".

ROYAL INSTITUTE OF CHEMISTRY (joint meeting with the CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY CHEMICAL SOCIETY, at the Chelsea College of Science and Technology, Manresa Road, London, S.W.3), at 7 p.m.—Prof. G. A. D. Haslewood. "Newer Chemistry of Bile Acids and Alcohols".

Thursday, March 9

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. D. P. Craig, Mr. J. M. Hollas, Mr. M. F. Redies and Mr. S. C. Wait: "Analysis of the Naphthalene Vapour Absorption Bands at 3200 Å. I. Naphthalene *h*-8. II. Naphthalene *d*-8".

Friday, March 10

ASSOCIATION OF APPLIED BIOLOGISTS (at Rothamsted Manor, Harpenden, Herts), at 10.50 a.m.—Meeting on "Aspects of Crop Physiology".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. Ronald King. "Energy".

Saturday, March 11

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. C. M. Mitchell: "The Folk Life of the English People".*

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

BIOCHEMIST for the Wellcome Laboratory, situated at the Veterinary Hospital—The Secretary of the University Court, The University, Glasgow, W.2 (March 10).

JUNIOR RESEARCH FELLOW IN CHEMISTRY—The College Secretary, Balliol College, Oxford (March 11).

LECTURER, and an ASSISTANT LECTURER, IN BOTANY; an ASSISTANT LECTURER IN CHEMISTRY; an ASSISTANT LECTURER IN PHYSIOLOGY; and an ASSISTANT LECTURER IN ZOOLOGY—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8 (March 11).

LECTURER IN APPLIED MECHANICS—The Registrar, The University, Leicester (March 11).

RESEARCH ASSISTANT (BIOLOGIST or CHEMIST) at Poole, Dorset, to assist in research on the tank culture of bivalve shellfish, under the supervision of the professor of zoology, University of Southampton—The Secretary and Registrar, The University, Southampton (March 11).

RESEARCH ASSISTANT (non-medical or medical graduate), to study wound healing by light and electron microscopy—Prof. R. J. Harrison, Anatomy Department, The London Hospital Medical College, Turner Street, London, E.1 (March 11).

ASSISTANT LECTURER IN PHILOSOPHY; and an ASSISTANT LECTURER IN MORAL AND POLITICAL PHILOSOPHY—The Registrar, University College of North Staffordshire, Keele, Staffs (March 14).

RESEARCH ASSISTANT (preferably with experience or an interest in comparative endocrinology or histochemistry) IN THE DEPARTMENT OF ZOOLOGY—The Registrar, The University, Nottingham (March 18).

RESEARCH STUDENTS (2) (suitably qualified in zoology, biochemistry or pharmacology) in the Wellcome Laboratories of Pharmacology, the Gatty Marine Laboratory, St. Andrews, for work on thyroid metabolism and physiology of lower vertebrates—Joint Clerk to the University Court, College Gate, St. Andrews (March 18).

LECTURER and an ASSISTANT LECTURER IN PURE MATHEMATICS—Dr. F. G. Friedlander, Secretary of the Appointments Committee of the Faculty of Mathematics, The University, Arts School, Bene't Street, Cambridge (March 22).

ASSISTANT LECTURER (trained in electron microscopic techniques) IN BIOPHYSICS—The Registrar, The University, Manchester 13 (March 25).

LECTURER IN CHEMISTRY (INORGANIC)—The Secretary, The University, Aberdeen (March 25).

LECTURER or ASSISTANT LECTURER (qualified in pure or applied mathematics) IN MATHEMATICS—The Registrar, University College of North Staffordshire, Keele, Staffs (March 25).

PROFESSOR (with a higher degree, preferably a doctorate, and with research experience in the field of animal husbandry) OF ANIMAL HUSBANDRY within the Faculty of Veterinary Science, University of Queensland—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, April 15).

COMPUTER OFFICER IN THE SUB-DEPARTMENT OF NUMERICAL ANALYSIS—The Registrar, The University, Liverpool, quoting Ref. No. CV/T.

DISTILLERS COMPANY RESEARCH STUDENT IN THE DEPARTMENT OF CHEMICAL ENGINEERING, for work leading to a higher degree on the kinetics of the gaseous oxidation of aromatic hydrocarbons—The Secretary, University College, Gower Street, London, W.C.1.

HEAD OF THE DEPARTMENT OF SCIENCE, Grade II—The Principal, Loughborough College of Further Education, Greenclose Lane, Loughborough.

POST-DOCTORAL FELLOW IN THE CHEMISTRY OF THIOAROMATIC COMPOUNDS IN ACID SOLUTIONS; the research will involve organic chemistry and electron spin resonance spectroscopy—Prof. H. J. Shine, Texas Technological College, Lubbock, Texas, U.S.A.

SCIENTIFIC OFFICER (male or female, with an honours degree in science, pharmacy or biology), for duties consisting of technical work in the Blood Transfusion Service Laboratories—The Director, Blood Transfusion Service, Roby Street, Manchester 1.

SCIENTIFIC OFFICER (with a good honours degree in biochemistry or chemistry and with a particular interest in lipid metabolism), to investigate the interrelationship between sterol and fatty acid metabolism in animals—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 61/7.

SENIOR LECTURER (with an honours degree and suitable teaching and research experience, and preferably higher degrees and specialization in modern atomic physics) IN PHYSICS—The Clerk to the Governors, South-West Essex Technical College and School of Art, Forest Road, Walthamstow, London, E.17.

SENIOR TECHNICIAN (preferably with G.C.E. ("A") level in either biology or zoology) IN THE ZOOLOGY DEPARTMENT, to assist in research of Prof. P. B. Medawar and his group on transplantations—The Secretary, University College, Gower Street, London, W.C.1, quoting "Zoology/1".

CONSERVATION OF NATURAL RESOURCES

ONE *important gap in responsibility revealed by* the review of scientific effort in Britain made by the Advisory Council on Scientific Policy at the request of the Minister for Science relates to the conservation of natural resources—minerals, land use and biological resources. The responsibilities of the Nature Conservancy cover only limited aspects, and as its annual report shows (see p. 798), even these are interlocked with the responsibilities of other Departments, which may or may not be responsible to the Minister for Science, as well as with the interests and responsibilities of various public or private bodies. The Advisory Council was satisfied that there is a significant absence of basic research in such major problems as the conservation and long-term utilization of water-supplies in Britain, while in formulating the considerations on which policies of land utilization should be based, much remains to be done towards a scientific classification of land capability, including the application of soil science and comprehensive topographical investigations.

On these subjects the Advisory Council is continuing its discussions with the authorities concerned, and meanwhile a study of the competition for rural land by Dr. G. P. Wibberley, of the Department of Agricultural Economics, Wye College, shows the value of research on land reclamation and the need for further effort in this field. The Advisory Council also stressed the need for study of the effect of long-term climatic changes on policy for the conservation of resources, and in view of its suggestion that the application of research in tropical ecology would facilitate the economic planning and execution of development schemes for under-developed countries, it is particularly disappointing to find that the recent report, *Colonial Research 1959–60*, contains no hint that the Overseas Research Council is addressing itself with any vigour to the problem of providing continuity of research in tropical agriculture and medicine in the emergent territories of the Commonwealth. Generally, however, the Advisory Council believes that the conservation of natural resources may be of sufficient importance to justify establishing a research council with central responsibilities, to ensure that, over the whole field, scientific knowledge and research are brought to bear on all these issues; the problem is being considered in detail by the Biology and Allied Sciences Committee of the Council. This suggestion for a further research council found some support in the debate on scientific policy in the House of Lords on November 9, though Lord Shackleton thought that in the first instance the functions and responsibilities of the Nature Conservancy might be extended to enable it to do the work. Lord Hailsham did not specifically reject this suggestion, though he pointed out that the Agricultural Research Council is also working in this field and he thought that we should first have a very clear idea of how any new research council would fit into the general scheme and what sort of work it should be asked to undertake. These matters will doubtless be elucidated by the Advisory Council's sub-committee which is considering the problem; in the meantime the Nature Conservancy states in its annual report that it is already most carefully considering a number of recommendations made by the Advisory Council on subjects of importance to the conservation of natural resources of Britain.

The Nature Conservancy's annual report, however, brings out once again not only inherent inadequacy on the part of the Conservancy to deal with such matters but also the inadequacy of the resources at its disposal. Its grant-in-aid for 1959–60 was no more than £336,000, and after providing some £205,000 for staff and £91,000 for properties and equipment, only some £44,231 was spent on research, training and special surveys, of which £21,509 was in research grants and £14,021 on studentships and training grants. It is scarcely surprising that applications for studentships or for places in the postgraduate diploma course in conservation should far exceed the number of awards the Conservancy is able to make, and the urgent need in conservation for recruits of high calibre to lead and inspire the growing movement of naturalists' trusts continues. Again and again the report refers to fields in which available information is inadequate, but in which no systematic efforts are yet being made to supply the lack; and it is obvious that the directions in which, with its present resources, the Conservancy can increase its efforts are severely limited.

More scientific and technical knowledge about the coast of Britain is needed, and the natural forces and threats affecting it; and on developments here the report quotes as still relevant the judgment two decades ago of the Coastal Preservation Committee, that the question how amenities and facilities shall be designed, where they shall be sited and how the essential characteristics of the coast and the adjoining landscape can be saved from destruction in the process, is urgent and vital in the absence of national control. In this particular field the Conservancy is promoting a fresh survey of the preservation of the coastline of England and Wales, but the report concludes with the judgment: "Almost every day brings new evidence of the price of our present methods of pursuing economic progress. Poisoning of wild life, pollution of seas, shores and rivers, destruction of irreplaceable scientific and amenity features and the exposure of vulnerable flora and fauna to excessive and unreasonable human pressure are among the current threats with which conservation must contend".

Part of the story of the struggle is told in the report, and the Conservancy's hope that enough of the picture will be made plain to awaken public opinion before it is too late should be widely shared by scientists, not least because of the way in which scientific interests themselves have been sacrificed. The picture, however, is not entirely black, and before referring more particularly to the glaring example of Dungeness, some of the encouraging features noted in the present report should be mentioned. First and foremost are the clear signs that the need for conservation, and the efforts of the Conservancy to that end, are becoming better understood and more widely accepted. This is notably true among the universities, as is illustrated by the support given by the University Grants Committee, which enabled the first advanced training course in conservation and ecology to be initiated at University College, London, and by the agreement of the University of Aberdeen to the establishment of the Conservancy's first research unit dealing with grouse and moorland ecology. The Welsh headquarters of the Conservancy and Research Station, opened at Bangor last July, is a notable addition to scientific institutions in Wales; its equipment includes an X-ray vacuum fluorescence spectrograph for elemental analysis of soil and plant material which will greatly reduce the time taken in analysis. An experimental station is also being planned on a site adjoining the Monks' Wood Nature Reserve; this will house the scientific group being formed to study problems of chemical spraying in relation to wild life and also other groups undertaking research on woodland management by natural methods in natural areas, the ecology of vertebrates (particularly mammals and birds) and scientific methods of conservation.

The high esteem for British progress in the field of conservation was manifest when many overseas scientists attended the celebration of the tercentenary of the Royal Society; this event was preceded by a meeting and tour of the British Commonwealth Scientific Committee, in the course of which the heads of all the principal Commonwealth scientific departments visited the Conservancy's Merlewood Research Station, while in June leading workers in this field were entertained and consulted on their way to attend the meetings in Poland of the International Union for the Conservation of Nature and Natural Resources. Evidence of Government interest in conservation was also seen in the promptness with which the Minister of Education acted on a recommendation of the Albemarle Committee and made a grant to the Council for Nature to enable the Conservation Corps to be expanded. The report again pays tribute to the value of the Conservation Corps in easing the difficulties due to the present shortage of field-staff in the reserves.

These and other events have all assisted to create a better-informed public opinion; and the Nature Conservancy has made its own direct efforts to that end. To assist the reconciliation of public access with scientific research and conservation, the Conservancy, in May 1960, signed an agreement with the Hampshire County Council under which the latter undertook to assist, so far as it properly can, towards the preservation of Old Winchester Hill and to help ensure that its extensive use by visitors does not cause injury or disturbance to this fine view-point or to its plants and animals and the studies which are being made of them. The Conservancy has also taken the initiative in seeking compromises or efforts of reconciliation between conservation and other interests in various areas where conservation is threatened by pressure of growing population, and in particular, promising informal discussions have taken place on the preservation of the coast-line.

Reference has already been made to the bearing of the Conservancy's work on wild life and agriculture overseas. The Government's concern for wild life in Africa was explicitly affirmed by the Colonial Secretary in the House of Commons last June, when he said that wild-life conservation measures are continuously under review in the East and Central African territories, but that more use could be made of technical knowledge in developing the wild-life resources, which contribute considerably to local food supplies, as well as being of economic value to the tourist industry. He recognized also the voluntary co-operation of the African populations, and welcomed the prospect of a conference on conservation in Africa being convened in 1961. The deputy-director-general (scientific) of the Conservancy, Dr. E. B. Worthington, has already submitted to the Colonial Secretary a full report on his extensive tour of East and Central Africa during February 7–March 19, 1960, and his report emphasizes the critical importance of conveying to the masses of the indigenous African people the economic importance of the conservation of African wild life and of securing the interest of their leaders. It also indicates the real assistance which the Nature Conservancy can give both in the application of technical knowledge to local management problems and in the training of staff.

Meanwhile, at the meeting of the International Union for the Conservation of Nature and National Resources held in Poland, an African Special Project was accepted as a major activity of the Union during the next three years. This project, which is to be launched in close co-operation with other international agencies, aims particularly at influencing African public opinion towards the conservation and wise use of natural resources, including wild life. Nor, as the report shows, are the overseas functions of the Nature Conservancy limited to Africa or to wild animals.

There are thus wider reasons than domestic ones why every care should be taken that the Conservancy's resources in finance, in staff and equipment are adequate to fulfil the increasing responsibilities which fall on it. Apart from the time factor stressed by the chairman in his report, Britain's scientific prestige is to some extent now involved by the new overseas commitments; and it should be a matter of urgency that the Minister for Science should satisfy himself not merely that adequate resources are available to the Conservancy, but also that the administrative structure is appropriate, including the relations with the Overseas Research Council and the Agricultural Research Council.

Nor is it simply a matter of adequate finance. Government interest must be much more positive than in the past. The Nature Conservancy is dissatisfied, for example, with the protection afforded by Sites of Special Scientific Interest status, and is examining, through discussions with the National Parks Commission, the Council for the Preservation of Rural England and other bodies, the possibilities for improvement. Too often, while sites may be protected against building or other forms of statutory development, the scientific interest is damaged or even obliterated by planting of trees, draining or ploughing, since forestry and agricultural development are not subject to planning control. Moreover, in conservation as a whole, there are still difficulties in assessing with sufficient precision for management purposes the scientific significance of an area.

The gravest threats, however, still come from the Government itself, and the Conservancy's comments on the Dungeness decision make most disturbing reading. In view of the decision announced in July 1959 to authorize a nuclear power station within the boundaries of the proposed reserve at Dungeness, the Conservancy decided not to proceed with the proposed reserve in view of the severe loss to the scientific interest. In announcing this decision on November 24, 1959, the Conservancy said that study of the direct and indirect repercussions of the power station on the remaining area showed that the future scientific interest would be too much reduced to qualify it for the status of a national reserve. The undeveloped area will remain 'designated' as a site of special scientific interest, and the Conservancy will continue to be consulted about any future development which may be proposed for other parts of the area; and in particular it will welcome and encourage any measures which the Royal Society for the Protection of Birds may take for maintaining and defending the fauna and flora, and especially the bird life of the 1,234 acres of shingle which it owns between the power station site, the Lydd Army Ranges and the bungalow settlement.

Nevertheless, as stated at the public inquiry, the issue was that of a clear choice between the conservation of the unique natural interest of Dungeness for scientific research and education, and the exploitation of the area as an engineering site. What is disturbing is that, after scientific interests have been irredeemably sacrificed—and interests which were unique and irreplaceable and could have supplied information of the utmost importance in coastal defence work generally—it should appear that this sacrifice of an important national interest was not really necessary. As the Conservancy's chairman points out in this report, the nuclear power programme has since been revised and it has been decided, for example, that a station on the Wylfa site in Anglesey, approved as suitable, will not be required in the period up to and including 1966.

This possibility was pressed by the Director-General of the Conservancy at the public inquiry at Lydd in December 1958, when he asked if there were not a risk that the nuclear power programme might not be revised again in such a way that the authorization for the site at Dungeness might prove unnecessary. The Chairman of the Conservancy very rightly remarks in the present report that the frequency with which sites of the highest scientific or amenity interest are claimed on grounds of over-riding priority, when experience shows that the reasons given are quite frequently modified even before construction takes place, is a national problem which deserves further attention. The Nature Conservancy recognizes the difficulties of averting such situations; but it does not consider that all possible methods of anticipating them and of minimizing the resultant harm have yet been explored. Its report is submitted to the Minister for Science and refers to a number of matters which call for the Minister's particular attention. None, however, is more important or more urgent than that emphasized in this comment on the Dungeness decision, and it is of over-riding importance that the Minister should take every possible step to ensure that there is no repetition of the Dungeness blunder. If sacrifice of unique and irreplaceable scientific and national interest is demanded, the possibility of doing so in deference to ephemeral requirements should be absolutely excluded. Revision and alternatives should be sought first and not after the sacrifice has been made.

TRANS-ANTARCTIC EXPEDITION 1955—58

Trans-Antarctic Expedition, 1955–1958
Scientific Reports. No. 2: A Gravity Traverse of Antarctica. By J. G. D. Pratt. Pp. 22. 12*s*. 6*d*. net. No. 3: Seismic Soundings across Antarctica. By J. G. D. Pratt. Pp. 69. (London: Trans-Antarctic Expedition Committee, 22 Gayfere Street, S.W.1, 1960.) 30*s*. net.

THE accomplishment of the Trans-Antarctic Expedition as a feat of human endeavour has rightly taken its place alongside the notable journeys of Antarctic history. The first scientific reports by the Expedition's geophysicist, J. G. D. Pratt, have now been published. The work was carried out under very difficult conditions of travel and climate, and early delays during the journey due to crevasses meant that less time was available for scientific work while crossing the plateau than had been anticipated. The amount of work done under these conditions is impressive.

Report No. 2 on the gravity programme deals at length with the performance of the Worden gravimeter. After correcting for the somewhat variable drift of the instrument, the raw gravity results are presented. No calculated gravitational anomalies are given, since the necessary heights above sea-level will not be computed with sufficient accuracy for gravity reduction until appropriate International Geophysical Year weather analyses over the Antarctic continent become available. The author's estimate of possible errors of up to 5 milligals in the raw results seems reasonable. In view of the expected precision of the final elevation measurements, the gravimetric data should be satisfactory for determining the regional anomalies if sufficient measurements of ice thickness are available. Smaller relative errors between adjacent gravity stations should also be satisfactory for giving finer details of sub-glacial relief. A small section on the vertical motion of floating pack-ice and ice shelves, as estimated by the use of the gravimeter, is a useful side-line to the main programme.

Report No. 3 deals with the seismic shooting measurements of ice thickness. The interest of most readers will be centred on the six pages plus one sample seismic recording which deals with reflexion shooting during the crossing of the Antarctic plateau. The difficulties of operating complicated electronic equipment under onerous conditions were clearly overcome. However, the discussion of techniques and the amplitude of the echoes in comparison with the noise-level on the sample record from the South Pole show that much could have been gained had the Expedition been able to take efficient power-drilling equipment on the crossing, so that the seismic shots could have been fired at depths of 20–30 m. or more. This had been shown to be very desirable by similar work on the Antarctic plateau by the Norwegian-British-Swedish Antarctic Expedition, 1949–52. Pratt concludes that the use of greater shot depths is the most promising single line by which improvement of results may be attained, and recommends that equipment to drill to 50 m., if not 100 m., should be carried in future.

The selection for publication of a seismic record obtained at the South Pole could not have been bettered if publication of only one record was practicable. The record is stated to be of typical quality; in due course it is hoped that it can be compared with those of shots fired by two other expeditions at the same point. Pratt marks two weak echoes on his record, the first at an uncorrected arrival time of 1·021 sec., the second at 1·438 sec. The first echo is used to determine the depth of ice at 1,990 m. This compares with a Press report of a depth of ice of about 2,500 m. obtained by Linehan (United States) shortly before Pratt's arrival, and a depth of 2,810 m. obtained by Kapitza (U.S.S.R.) in December, 1959, and published in a paper by Dralkin (*Priroda*, No. 10, 27, 1960). There is no reason for preferring Linehan's preliminary result to Pratt's value, since both were obtained with shot-depths less than 10 m., but since Kapitza fired his shot at a depth of 50 m. one is inclined to prefer his result. If Pratt's second echo (1·438 sec.) is taken to come from the bottom of the ice, it would give a depth in agreement with Kapitza's value. I would agree with the clear discussion of the possibility of errors in picking echoes from the sub-glacial floor, except that Pratt discounts the possibility of noise on the record being mistaken for the required reflexion, as may have happened in this case.

Clearly those interested in measurements of the thickness of ice who are not specialists at seismic shooting will wish to know why different individuals produce different answers for ice depths at one point. On the outer parts of the Antarctic continent, where ice temperatures are above −30° C., it is not difficult to produce first-class results from most areas of inland ice. Some fully reliable results have also been produced on the Antarctic plateau, and there is no doubt that the overall picture of great depths of ice over much of Antarctica is correct. However, under noisy shooting conditions on very cold firn, echoes may not show up clearly against the noise, or a double reflexion may show up when the first reflexion is obscured. Some risk of error clearly arises under these conditions. One can hope to eliminate most errors by making sure that data from seismic soundings, gravimetric measurements, surface slopes of the ice sheet and perhaps magnetic measurements are consistent with one another. The preliminary results of the Norwegian-British-Swedish Antarctic Expedition 1949–52 on the depths of floating ice-shelves had to be reviewed on such a basis. A similar revision of ideas of the thickness of the ice at the U.S.S.R. Vostok station has taken place (Kapitza found a thickness of 3,700 m. compared with an earlier seismic shooting value of 1,800 m.). It is apparent that we shall get the best value from the Trans-Antarctic Expedition results only after a thorough comparison of gravitational anomalies and surface slopes with the possible seismic echoes has been made. It is therefore hoped that when the final report on gravitational anomalies is prepared, such a reassessment of all the data will be made. It will also help the individual research worker if more of the reflexion records obtained while crossing the plateau can be published at the same time

The remaining fifty pages of the report cover work of more specialized interest on refraction shooting at South Ice, and an extensive analysis of the methods and errors involved in determining the thickness of the ice shelf near Shackleton by use of strong reflexions from the sea bottom.

Pratt writes clearly with a rather informal style which shows a healthy disrespect for established ideas that do not have a firm basis. No bibliography is included in either report. The format, printing and general production of the reports are of high quality.

G. DE Q. ROBIN

SAHARAN ETHNOGRAPHY

Tribes of the Sahara

By Dr. Lloyd Cabot Briggs. Pp. xx+295+33 plates. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1960.) 32*s*. 6*d*. net.

ACCORDING to Dr. Briggs, "More pure balderdash has been written and repeated about the tribes of the Sahara than about almost any other peoples in the world". In *Tribes of the Sahara* he sets out to correct this, and to show that "the sober truth about the Sahara is more mysterious than anything that has been written about it". But the Sahara is essentially a French literary possession and the mystery and romance which it evokes in French writers disappear when reduced to arid Anglo-Saxon prose. It changes into a mirage of unstable, unattainable hypotheses, and the reader finds himself abandoned in a shifting sea of desiccated gritty facts—that a camel's rate of water elimination is "less than a third of the average figure for mammals in general" (p. 28); that the underground aqueducts locally known as 'foggaras' 'may have been introduced" into the Sahara by the Persians (p. 12); that the best Touareg sword-blades "were imported from Northern

Italy, Germany and Spain" (p. 149); that their kinship structure gives "the distinct impression of a double descent system" (p. 134); that the "sedentary women of Metlili go without trousers as a rule" (p. 208).

The book falls between two stools. It has far too many 'scientific' facts of this sort to make it a successful travel book; on the other hand, there are far too many theories and insufficient supporting data to make it acceptable to anthropologists, archæologists or historians. Human geographers, however, should find it very useful, for it answers their need for a descriptive summary of the peoples of the Central and Western Sahara which is both up to date and accurate, and which takes care to distinguish between fact and fantasy. That the latter still occupies so much space is not a reflexion on Mr. Briggs's scholarship but on the weakness of anthropological fieldwork in this part of Africa. One could have wished, however, that he could have spent less of his twelve years of study in "threshing and winnowing all the Saharan literature that he could lay his hands on", and more time in field research among the Chamba and other representative communities.

The book is supported by two very inadequate sketch maps, thirty-three good plates and an impressive bibliography. G. I. JONES

THE ECOLOGY OF AFRICAN GAME

Wild Life in an African Territory

By Dr. F. Fraser Darling. (A Study made for the Game and Tsetse Control Department of Northern Rhodesia.) Pp. viii+160. (London: Oxford University Press, 1960.) 25*s*. net.

THIS book is primarily a report of a survey carried out by the author in Northern Rhodesia, with the object of examining the present status of the wild African game, the natural vegetation where it survives and the problems involved in the conservation of wild Nature in this territory. Much of the book is thus an account of the journeys undertaken and the terrain examined, followed by an ecological description of the vegetation and the habitats. The book concludes with an account of the measures of nature conservation already undertaken by the Government, and with recommendations for future action. There are, in addition, three appendixes, a directive on wild-life conservation issued by Sir Evelyn Baring as governor of Kenya, an official circular issued to all provincial commissioners in Northern Rhodesia on the same subject, and finally, a paper dealing with the status of the more important ungulates in Northern Rhodesia.

These materials are largely matters of record, though they give an excellent idea of the present condition of the country, and are valuable as a record and for comparison with such earlier data as are available.

In many ways the most interesting part of the book is the relation of this material to the underlying philosophy, and to the reflexions and observations embodied in the introduction and the middle chapters in which the ecology of African biological communities is discussed. Here the author draws freely on his wide experience to generalize. His view is that many of the existing habitats and biological communities in undeveloped Africa represent ecological climaxes which yield the maximum biological production possible under the difficult climatic and ancient soil conditions prevalent. This is mainly because the organisms present include a multitude of highly adapted plants and animals, the diversity of habit and function of which exploits to the full every variety of ecological niche. It follows that a disturbance, and especially a simplification, of the ecological system (such as follow human 'development') is almost certain to lead to degradation of production and to site deterioration. There is therefore a case for maintaining the existing habitats and wild-life systems until further inquiry may disclose methods of land-use which can be fully equated with the natural systems already existing.

Dr. Darling applies this generalization to the particular problem involved in the conservation of the ungulate African animals and their habitats, including the human societies involved in his treatment of this eco-system. He considers that the game can be conserved and also used to give an adequate supply of protein food for Africans in the territory and this, rather than known alternative forms of land-use, offers the best prospect of preserving rather unstable habitats and also perhaps of permitting time for the development of the primitive human social systems. He has succeeded in integrating his material so well as to give a valuable picture of the background and the relation between social life, land-use and ecology in the still savage parts of Africa. Thus the book is an important and useful illustration of the new scientific approach to these problems of wild-life management as well as to the ecology of land-use. W. H. PEARSALL

KINETIC THEORY OF GASES

Elements of the Kinetic Theory of Gases

By Prof. E. A. Guggenheim. (International Encyclopedia of Physical Chemistry and Chemical Physics. Topic 6: The Kinetic Theory of Gases, Vol. 1.) Pp. xii+92. (London and New York: Pergamon Press, 1960.) 17*s*. 6*d*.

THIS is the first part of the *Encyclopedia of Physical Chemistry and Chemical Physics* to be published. It leads us to expect an outstanding work.

Treatments of the kinetic theory of gases have tended to fall into two classes: there are the comprehensive, detailed and somewhat involved accounts which are concerned to be rigorous, regardless of complexity, and, on the other hand, there are simple, approximate accounts, frequently using unsatisfactory assumptions. *Elements of the Kinetic Theory of Gases* seems likely to make a wide appeal to readers who find neither of the two classes satisfactory.

A skilful mathematical formulation of basic kinetic phenomena leads to treatments of successive topics which are both incisive and concise. Clarity is furthered still more by the organization of the material into virtually self-contained, short chapters. The result is that the reader is continually struck by the power of essentially simple procedures which penetrate to the core of a problem, as, for example, in the derivation of Maxwell's distribution law. Again, collision-rates are considered with rigour but without complexity. Simplicity is not shunned even where rigour is lacking, provided it affords insight. The naive treatment of viscosity is given, though to be sure it is followed soon enough by an account which does not assume Maxwellian distribution of velocities; there are parallel treatments of thermal conductivity. On the other hand, no attempt is made to include simple theories in the sections on diffusion and thermal diffusion.

In the final chapters on gas imperfections and intermolecular forces, the fashionable 6–12 potential function is severely scrutinized, and the difficulty of obtaining inter-molecular potential functions from second virial coefficients alone is exposed. A synthetic five-parameter function is advanced and shown, for argon, to give an impressive account of the dependence on temperature not only of the second virial coefficient but also of the entropy, heat content and density of the solid.

The book is aimed at graduate and research workers, but the mathematical treatment is such that undergraduates in their final year could profitably read much of the earlier and later chapters of the book. It is not only part of an encyclopædia to be consulted and referred to, but also a book to be read and enjoyed. D. J. MILLEN

INVISIBLE LUNATIC

Automatic Translation

By D. Yu Panov. Translated from the Russian by R. Kisch. Edited by A. J. Mitchell. Pp. vii+73. (London and New York: Pergamon Press, 1960.) 21*s*. net.

Automatic Language Translation

Lexical and Technical Aspects, with particular reference to Russian. By Prof. Anthony G. Oettinger. (Harvard Monographs in Applied Science, No. 8.) Pp. xix+380. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1960.) 80*s*. net.

THE title of this review is prompted by the story, until recently apocryphal, that a Russian computer translated the phrase "Out of sight, out of mind" from the English and that an American machine, in due course, re-translated the Russian back into English with the above result.

In so far as this story has a point, it is illustrated by the two books under review. Both are the first generally available technical reports produced by mechanical translation workers in their respective countries. By saying this I do not in any way mean to neglect the volumes of brief essays which have already appeared or the excellent reports, of limited circulation, which some American groups have issued.

Both books describe the activities of single groups of workers, and both are coloured by the particular machines used for the experiments.

Panov's book starts by discussing how human beings go about the act of translation, and then, after examining the characteristics of scientific and technical prose, describes the electronic computer *Besm* 1 and experiments made with its aid in this field. Detailed programmes are analysed and there is a critical survey of the present theories of translation.

Oettinger follows similar lines, except that his machine is the *Univac* 1, and that he is far less concerned with translation theories than with the precise details of Russian–English dictionary construction.

On balance it is fair to say that Panov's book will be far more readable to the non-specialist and, correspondingly, far less useful to workers in the field. Oettinger's book is nearly five times as long and is packed with useful data for the specialist.

Both books are excellently written and can be thoroughly recommended. A. D. BOOTH

ALL ABOUT MANGOES

The Mango

Botany, Cultivation, and Utilization. By Dr. Lal Behari Singh. (World Crops Books.) Pp. xiii+438+54 plates. (London: Leonard Hill (Books), Ltd.; New York: Interscience Publishers, Inc., 1960.) 84*s*. net.

IT is pleasing, as it is unexpected, to find a new series of books on world crops starting off not with such solid fare as wheat or potatoes or cabbage but with something as exotic and appetizing as the mango. This "choicest fruit of Hindoosthan" has spread far beyond the bounds of India and has become one of the most cherished fruits of tropical lands. It is still found in greatest variety and excellence in India, and this book comes, fitly enough, from the pen of a distinguished Indian horticulturist.

The book may be counted on to commend itself as the most complete study of the mango so far published. There has indeed been a recent book, also entitled *The Mango*, which splendidly described the Indian varieties, but had only a short account of their cultivation. Dr. Singh deals with the subject on a broader front, concerning himself not only with the botany and requirements but also with propagation and management, the diseases and pests to be withstood, and the uses to which the mango is put.

While the botanical chapters refer mainly to the common mango, *M. indica*, the author directs attention to fifteen other species of *Mangifera* with edible fruits. Evidently there is great wealth of related material here, of possible value for future breeding. A clear and well-illustrated account is given of methods of vegetative propagation. In describing the practice of cultivation, the author is strangely insistent that the established orchard needs ploughing twice a year to maintain a proper soil tilth. It is not clear why such a disturbance is preferred to maintenance of a more natural leaf-litter. The section on utilization is necessarily brief, since the best way to use a mango is still to eat it as promptly and as dexterously as possible, but some mango recipes are also given. A full bibliography and a good index complete the work.

The book could have done with some tidying up, for misprints and some not quite lucid passages occur. In striving for completeness, the author tends to length, and his more impatient readers may grudge the space given to explaining what a horticultural variety is, or the detail spent on different methods of applying irrigation water to a tree which, over much of its range, is satisfied by the rain from heaven. In giving such full measure, the author doubtless errs on the right side, and his book deserves to be welcomed and to be gratefully added to the small, but growing, collection of hand-books on the tropical crops. T. A. RUSSELL

A TURNING POINT IN THE STUDY OF INSECT MIGRATION*

By DR. J. S. KENNEDY

Agricultural Research Council Unit of Insect Physiology, Entomological Field Station,
34A, Storey's Way, Cambridge

C. G. JOHNSON[1] has crystallized a new trend, since the War, in the field of insect migration and dispersal by flight. The trend is inspired largely by work on aphids and locusts, which has been more intensive than that on economically less-important insect migrants such as butterflies. The new knowledge gained cannot be fitted into the previous framework of behavioural ideas due to C. B. Williams[2-4]; therefore Johnson (working on aphids) and Rainey[5] (on locusts) propose shifting the emphasis to the timing and results of migration. This would mean abandoning, along with his particular ideas, Williams's general aim: to characterize migration ecologically, behaviourally and physiologically. The purpose of this article is to suggest that the recent advances, far from giving cause to abandon that aim, have brought it within reach.

Records of migrating insects other than locusts have been collected and collated for many years under the leadership of Williams, and the outstanding achievements of this work are: the demonstration that migration is much commoner than was supposed, even if we count only the long-range and geographically clear-cut cases that Williams considers; and secondly, the detection of apparent return movements in an ever-growing number of species. Lack of evidence of any return in many cases had previously posed a problem of the evolutionary origin of the migratory habit and lent colour to the idea that migration served mainly to reduce high populations[6]. But in all the observations so collated the chief criterion used for distinguishing insects as migrant is the peculiarly persistent, undeviating manner of flight of butterflies, dragonflies, locusts and other large powerful fliers when close to the ground. This gives them a mysteriously purposeful air that rivets the attention of observers and makes teleological interpretation almost irresistible. This in turn proved an impediment to the development of the subject on the physiological and ecological sides alike.

Williams inferred that such migrants continue to fly low, holding to one compass direction for hours and days on end, and in this way directly determine the route of their long-distance movements. This has recently been disproved for locusts and questioned for some butterflies[7], and has not yet been verified for any insect. But taken as fact it posed an intractable problem of the mechanism of orientation. Williams even suggested that migrants had an innate sense of direction independent of the environment. There the matter of direction determination has rested, while other physiological problems of migration have remained in the background.

Furthermore, only insects flying in that self-propelled, self-directed manner were regarded by Williams as migrants. The dispersal of smaller, weaker, more buoyant insects such as winged aphids or moth larvæ that drift on the wind, merely supporting themselves by their wing beating or on silken kites, was not migration. Williams's definitions of migration are to be understood in that exclusive sense: "a change of location which is determined both in distance and direction by the insect itself, and not a passive distribution of individuals by overpowering forces such as strong winds"[3]; or "movement determined by the insect itself; [which] instead of being haphazard in direction, is straightened out so as to result in a change of habitat"[4].

Movements that result in a change of habitat are, of course, of major concern to ecologists[6,8,9]. They, however, regard regular long-range to-and-fro movements between discrete areas as special cases. Hence all the work done on such migration has seemed of doubtful relevance to everyday ecological work. Ecologists use the looser term 'dispersal' for the general phenomenon in which they are interested, and Elton's[8] description of dispersal as "taking place all the time as a result of the normal life of the animals" seems quite the opposite of Williams's basic idea of migration as a distinct biological process. In the absence of more information on dispersal mechanisms, ecologists who do believe there are distinct behavioural 'adaptations for dispersal', have had difficulty in describing them objectively[9].

Recent Advances

Locusts and aphids have, in the past, served as excellent illustrations of the supposed contrast between active migration and passive dispersal. But it turns out that locusts migrate on the wind no less than winged aphids: and winged aphids are, in their own way, no less specialized as migrants than locusts. Both are active, 'deliberate' migrants; and both achieve their long-range movements 'passively'. This is what has made a broadening of the idea of migration seem pressing[1,5].

The new phase opened in the locust work (mainly on the desert locust, *Schistocerca gregaria* Forsk.) when it was realized that the orientation of fliers and the direction of their long-range migrations were separate problems: the one did not directly determine the other[10,11]. The explanation of their purposeful air when seen flying close to the ground does not lie in any type of orienting stimulus capable of maintaining a fixed course and track for long periods. It could be explained in terms of familiar types of orienting stimuli from the immediate environment. These have a steadying effect on courses and tracks near the ground, but certainly do not fix them. For example, low-flying locusts, like butterflies and aphids as well as locust 'hoppers' migrating on foot, change course away from upstanding objects and so keep in the open where locomotion can be maintained. Non-migrating insects frequently turn toward such objects and are arrested.

---

* Based on papers contributed by the author to symposia on migration at the eleventh International Congress of Entomology, Vienna, August 18, 1960, and at the Anti-Locust Research Centre, London, September 22, 1960.

But low-level oriented flying achieves relatively little displacement over the ground. The more important way in which the swarming locusts' behaviour ensures that they travel is by their rising actively away from the ground and, moreover, allowing themselves to be lifted by convection, like aphids. In this way, they not only avoid obstacles (including such obstacles as the Atlas Mountains) but also pass out of range of any optomotor orienting effect of the ground pattern and ride the faster-moving upper air. Then, the only obvious orientation reactions are those of locust to locust counteracting the disruptive effects of air turbulence on the swarm. Groups of locusts within it show a common orientation, but this varies from minute to minute and group to group. Cohesion is maintained only because any group that approaches the edge of the swarm, on any side, turns back into it. Meanwhile the swarm as a whole is being bundled across country by the wind[5,11-16].

That this resultantly downwind mode of 'straightened-out' travel can be adaptive was demonstrated by Rainey[16] in an outstanding example of the application of modern synoptic meteorology to insect ecology. The rainfall desert locusts need for breeding occurs in different regions at different seasons, and results from the temporary convergence of winds upon each region, so that the wind-borne swarms always tend to be delivered to the right place at the right time. Thus a more or less regular seasonal to-and-fro pattern of migrations between geographically discrete regions, on the familiar vertebrate model, and by large powerful insects, can be created not by self-directed flights but by 'passive' displacements. It may still be true that the long-range to-and-fro migrations of some butterflies do not depend on such displacement and are actively oriented, but the onus now lies on students of butterflies to prove it.

That the long-range movements of winged aphids are effected by passive transport on the upper air has been very thoroughly confirmed (mainly with the black bean aphid, *Aphis fabae* Scop.)[17,18]. But their embarkment on, remaining in and disembarkment from this transporting vehicle all depend on active locomotor responses[19]. Embarkment depends on a sharp rise in locomotor excitability in the fresh adult which is triggered into flight, and then directed up out of the vegetation into the free-circulating air, by the bright, predominantly short wave-length light from the sky. This oriented 'straightening out' of its movement does not take the aphid far, but again the direct result is a passive, long-range straightening out of its movement by the fast-moving upper air. Disembarkment depends on a change in the reaction to light as flight proceeds, with a weakening of the kinetic effect and of the attraction to sky light and a relative strengthening of the attraction to the longer wave-length light reflected from plants. Before the phototaxis reverses lastingly to negative, there are intermediate phases when the insects fly about actively near the grouud, orienting into and making headway against gentle air-currents and avoiding obstacles, like locusts, and eventually making the alightments by which the flora is sampled for suitable host plants. The intensely active nature of the migratory flight is obvious even in this phase, for the great majority of alighters, even on their own host plants, take off again within minutes.

There is, in fact, a definite inhibition in the young adult of the usual settling, feeding and larvi-position responses to visual and other stimuli from plants, together with an arrest of embryo growth in the ovaries. When the inhibition is eventually removed, by locomotion, embryo growth restarts and at the same time the flight muscles degenerate and the fat body enlarges[19,20]. The restriction of the frenetic migratory activity of these aphids to, at most, a few days and usually a few hours out of the individual's otherwise sedentary life, further underlines the differentiation of migration as a biological function.

What all this means, as Johnson justly insists, is that migration is part of the normal development of winged aphids, "an evolved adaptation"[1]. It is not their reaction to crowding, food shortage or other current adversity as Elton[6], for example, supposed most migrations to be. Nevertheless, although obligate in the winged form of aphid, migration is facultative for the species. Production of the winged form is the response of the wingless form to crowding and other signals of impending adversity. With locusts, too, migration of the persistent lifelong type seen in the gregarious members of swarms is not obligatory but facultative for the species and results from a heritable response to crowding. Migration is often facultative without obvious polymorphism, as in the pierid butterfly *Ascia monuste* L., where it seems to depend on both population density and the time of day of emergence[21]. If, as Southwood argues, migration is usually an adaptation to a temporary habitat[22], then whether it is obligate or facultative may depend on whether the habitat typically lasts long enough for only one generation or for more.

Proposed Non-behavioural Definitions of Migration

Rainey[13] claims with justification that recent work on locusts has "dispelled some of the mystery" in Williams's picture of migration. The mystery was primarily behavioural, and in dispelling it neither Rainey nor Johnson puts anything in its place so far as behaviour is concerned, rather shifting the emphasis to some other aspect of migration. Thus Rainey insists that the effects of vertical and horizontal air-currents on insect displacement must be assessed before the "finer effects" of behaviour, "in order to distinguish what the organism is itself doing from what is being done to it by the environment"[13,16]. But Rainey has himself reported that the members of small swarms do not allow themselves to be dispersed upwards, like aphids, by turbulent convection, when the members of large swarms do[15]. This is but one illustration of the need to assess what both the insect and the environment are doing, simultaneously. Rainey suggests that migration is "more usefully characterized by a seasonal displacement of populations than by directionally purposeful behaviour"[5]. The qualification "seasonal" is not generally applicable since aphids and other insects often migrate in response to irregularly arising local conditions. It is not necessary to fall back on a purely ecological description like "population displacement", for "directionally purposeful behaviour" is no longer the only alternative.

Johnson recommends distinguishing migration flights "chronologically in the first place before attempting to distinguish them behaviourally"[1]. Disregarding migration other than by flight, he adduces evidence that migratory flights usually occur as the first flights of new adults. There are a good many exceptions to this post-teneral rule, notably post-diapause migrations[4]. But most of them, although not all, would be covered if migration in adult insects were characterized as pre-reproductive, rather than post-teneral. This is an important new common feature recognized in migration: a pointer to developmental physiology (below). Nevertheless, it is as new adults that insects first fly anyway, so the timing does not distinguish migration. The timing of an event becomes of interest once we know what the event is.

Johnson gives two reasons for believing there is no satisfactory way of characterizing migration behaviourally[1]. He doubts whether there need be any difference of kind between migratory and other flights, and earlier questioned the validity of Berland's division of the atmosphere into "terrestrial" and "plankton" zones for flying insects[17]. But that general idea has now been revived in Taylor's concept of a "boundary layer"[18]; and Johnson[1] concedes there is a clear difference between migratory and other flights in Lepidoptera and mosquitoes. The difference is equally apparent in locusts[10,23] and aphids[19] and other insects[22]. His second and more important reason for omitting behaviour from his general system is that the behavioural qualities of migrants "are so variable that definitions based on them as to what is or is not 'migration' or what is 'active' migration and what is 'passive' dispersal become arbitrary, controversial and unsatisfactory when applied to all the types of insect that are said to migrate"[1]. It is true that those distinctions have now broken down, because they assumed a single mechanism of "straightening out" of movements, when as we have seen there are two, discussed further below. At the level of reactions to particular stimuli there is great variation; but the resultant straightening out remains a common feature.

Without that straightening out (the "klino-kinetic" component) even very persistent locomotor activity is not migration, for example in a stationary swarm of flying midges. But when combined with it, a second common feature is what Andrewartha and Birch[9] give as the main one: a special readiness to move (the "ortho-kinetic" component). Here again various stimuli and reactions may be involved. Persistent employment of the insect's own locomotor organs is most common; but there may be no more locomotion than that involved in leaving the feeding or hibernation site and releasing the foothold or clambering on the body of a winged migrant[22,24]. But again, a common feature remains in the special readiness to move and go on moving.

Negative Features of Migratory Behaviour

If we consider only those reactions that show heightened excitability (low threshold) in migrants, we cannot make any all-embracing generalization about them except in terms of their resultant effect: straightened-out movement. That common behavioural feature is important; but it does not entirely dispose of Johnson's difficulty, for it does not provide a ready means of distinguishing migration from such long unidirectional movements as those of an ant toward the nest, a chafer toward a clump of trees, a mosquito toward a host, or a male moth toward a female[25]. But a further criterion is available in what the migrant does not do.

In a migrant the persistently lowered threshold of responses resulting in straightened-out movement goes with a persistently raised threshold of responses that arrest and deviate movement. With locusts and aphids in mind, these more-or-less inhibited reflexes have been generalized as "vegetative", for lack of a better term, meaning responses promoting growth, of the larva or of the adult's genital products, through the exploitation of present resources[26]. The locomotor ones among them were called "station-keeping" responses. Migrants are distinguished by "a transient accentuation of locomotor functions with depression of vegetative functions, such that the insect now travels, by what method being a secondary matter"[19]. Nielsen and Nielsen[21], Blunck[27] and Provost[28] directed attention to this unresponsiveness in migrant butterflies and mosquitoes, and Andrewartha and Birch[9] made the same general point. Thus the Nielsens listed the reflex patterns of adult *Ascia monuste* "living in a territory" as feeding, mating, egg-laying, basking and cleaning, and reported failure to respond to the appropriate stimuli for any of these when the butterflies were engaged in unidirectional flight elsewhere.

The relative degree to which the diverse "vegetative" reflexes are inhibited varies greatly. But the grouping of them under one label is no mere descriptive convenience. In the aphid they are allied reflexes in the physiological sense, standing together in antagonistic relationship to locomotion[29]. This is so when the insect is not migrating also. But then the vegetative reflexes are readily excitable and only briefly inhibited centrally by a stimulus that provokes locomotion instead. When migration starts they are deeply and lastingly inhibited. A more complete characterization of migratory behaviour is then: persistent, straightened-out movement that is accompanied by and dependent upon the maintenance of an internal inhibition of those "vegetative" reflexes that will, eventually, arrest movement. Conversely, the locomotor reflexes (or other reflexes securing displacement) cannot for some while be inhibited by stimuli that do promptly inhibit them at other times.

The distance moved is indicative but not always a reliable criterion of migration, as Provost[28] and Andrewartha and Birch[9] point out, because an insect that is ready to respond to an arresting stimulus may not receive it for some time. Hunting and foraging movements may be very extensive, as in some mosquitoes, yet not be migration if the insects stop as soon as feeding stimuli are received. On the other hand, when an army ant colony, on the emergence of a new brood of worker adults, enters on a 'nomadic phase' in which the workers shift the larvæ to a new bivouac site every night along one of the trails they used for foraging that day, this is migration[30]. In the laboratory, starvation produces a high level of locomotor activity in blowflies; but this is not migration physiologically speaking, since the flies take sugar as soon as it is presented and as a result of filling their crops with it become lastingly less active[31]. On the other hand, when locust 'hoppers' or Mormon crickets[32] launch into 'marching' and are stopped only temporarily by suitable food plants, this is migration when compared with the behaviour of the solitary individuals. Young adult dragonflies which disperse in all directions away from the edge of the water in which they developed may also be showing an elementary form of migratory behaviour, because at this time they are positively repelled by the sight of water which will later attract them[33]. Teneral adult *Calliphora* will burrow for hours while they remain in soil, but this is not migration, for emergence from the soil at any time stops the movement[34]. On the other hand, the adult female of *Anopheles sacharovi* may truly migrate when it enters diapause in the autumn, for, unlike the non-diapausing female of previous generations, its flying is apparently not arrested by the first blood meal and shelter it finds, so that it travels far from the breeding place[35].

Thus there is an objective experimental method of deciding whether a moving insect is migrating or not, by measuring its responsiveness to the stimuli signalling the appropriate 'vegetative' requirement. This test has seldom been applied, so that it is often impossible to draw any firm conclusion from the literature. When the insects are known to travel on the upper air the tendency is to assume this is mere 'vagrancy': an 'involuntary' consequence of non-migratory behaviour under special conditions (Williams's "overpowering forces"). The spruce budworm (*Choristoneura fumiferana*) is a good case in point, for it has been studied extensively[24]. Much is known about the immediate triggering stimuli for flight and the air conditions favouring transport, but little about changes in the responsiveness of the individuals. It appears, however, that both larval and adult dispersal are increased actively when the population rises to very damaging densities. The reduced fecundity of the resulting undersized adults is partially compensated by their readiness to fly upwards and thus be transported to undamaged trees before depositing any eggs. The larger, more fecund females produced at less-damaging densities do not fly at all until after they have deposited one or two egg masses[24]. But whether there is any difference of kind between flights before and after oviposition, and whether there is a temporary internal inhibition of oviposition in the undersized females, are still unexplored questions.

The idea of temporary inhibition of 'vegetative' responses in migrants has often been conveyed in a subjective, teleological way that confuses means with ends and serves as a substitute for, rather than an invitation to, experiment. Migratory behaviour has been distinguished as not searching (for any vegetative requirement: food, mate, oviposition site, etc.), not internally oriented, non-motivated, non-appetitive[9,21,28]. The inference is that any movement with a specifiable end is not migratory (see Provost[28] on pre-hibernation flights of anophelines). But migratory and non-migratory movements both end with readiness to respond to some specific stimulus signalling a vegetative requirement or resting place, and in neither case is the movement directed by its end. In both, the locomotion is, in fact, centrally antagonistic to the reflexes that terminate it, at first inhibiting them and finally being inhibited by them in turn. The only objective sense in which a movement is directed toward an end is that the antagonistic arresting reflexes may be progressively 'primed' (thresholds lowered) as a result of being inhibited by the locomotion (successive induction[29]). The basic difference between migratory and non-migratory behaviour is a difference of relative thresholds. There is no sharp line of demarcation between them; we are concerned rather with degrees of functional differentiation in a particular direction, and our first concern is to identify that direction.

Physiological Differentiation in Migrants

The study of insect migration will remain in its present backward state until we know more of the sensory, nervous, endocrine and metabolic components of the mechanism by which migration is 'primed' (in addition to the immediate stimuli that elicit the primed responses) and likewise of the reverse changes that follow on migratory activity. The best information of this kind concerns aphids[30]; but generally there is little. Something is known about fat deposition in place of egg development in migrants[4] as in diapausing insects, about flight muscle development in place of eggs[36] and the use of fat as the most economical flight fuel for migrants[37].

Ecologically, migration sometimes looks like an alternative to diapause when conditions will no longer permit growth, development or reproduction[9,22]. It is so when the habitat deterioration is merely local so that vegetative activities can be resumed earlier elsewhere than *in situ*. It is not so when the deterioration is synchronized throughout the insect's range, as in a temperate autumn or dry tropical summer. Migration may then be, on the contrary, a condition for diapause, if that is also not possible *in situ*[4,22]. But physiologically, the important point is that migration is in either case at the expense of vegetative functions in the individual. The internal inhibition of certain reflexes is the behavioural component of a whole physiological syndrome.

Fig. 1 illustrates this by comparing the timing and amount of growth or reproduction in migratory and non-migratory (or less migratory) females of the same species in the laboratory, where actual migratory activity is minimal and vegetative requirements are continuously available. Solitary locusts (Fig. 1, right) migrate as young adults between seasonal habitats, but the syndrome is developed to an extreme in gregarious locusts which migrate throughout their lives and will not settle in any place[33,26]. Gregarious locusts may show hastened instead of retarded oviposition when there is a tendency to diapause governed by length of day, but in either case they lay considerably fewer eggs[41,42]. The garden chafer (*Phyllopertha borticola* (L.)) is another interesting variant[43]. All the females are ready to lay on emergence before any flight, and most lay their eggs then and do not migrate. The migrants are females that did not lay the bulk of their eggs on emergence and thereafter seem to have developed an inhibition of the reflexes associated with laying; they lay readily after migrating.

The nature of the physiological syndrome in migrants—accentuation of 'sensori-motor' functions with depression of vegetative ones—makes it easier

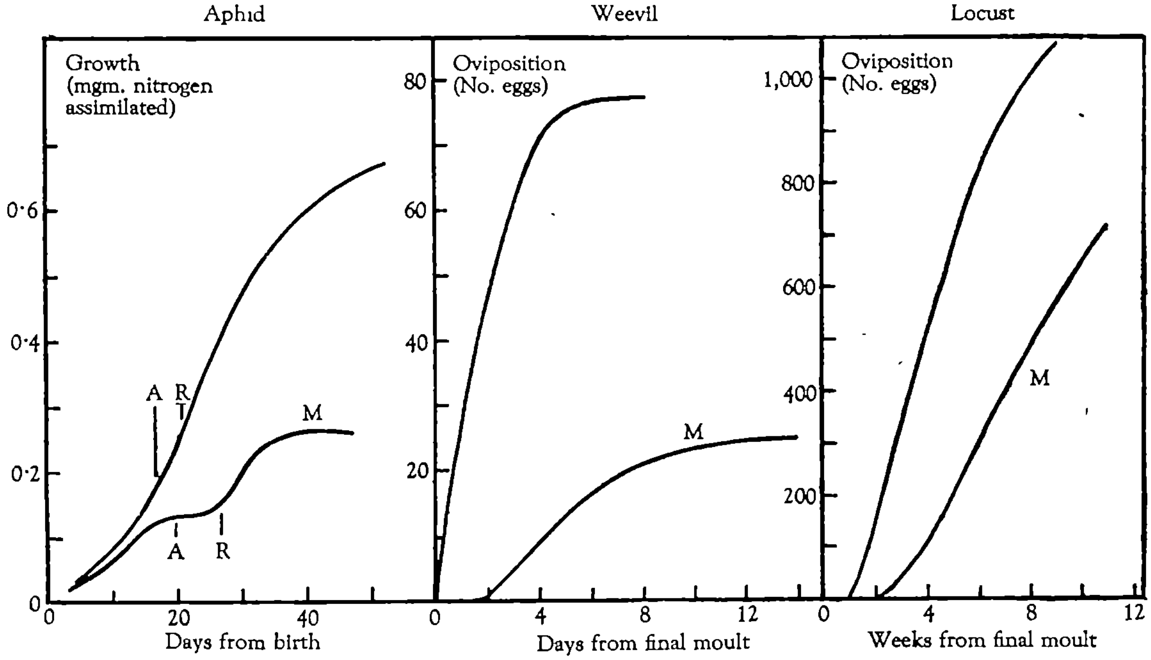

Fig. 1. Examples of the arrest and depression of growth functions in adult migrants (*M* curves). Left: *Tuberolachnus salignus* winged (*M*) compared with wingless form, after Mittler (ref. 38). *A*, final moult to adult; *R*, start of reproduction (larvi-position) after which the further rise represents embryo growth; Centre: *Callosobruchus maculatus* 'active' (*M*) compared with normal form (terminology of Caswell (ref. 39)), after Utida (ref. 40); Right: *Locusta migratoria migratorioides* gregarious (*M*) compared with solitary form, after Norris (ref. 41). All curves cumulative

to understand why migration so commonly occurs in the adult stage and is then usually pre-reproductive[1] or inter-reproductive. For reproduction involves a resumption of the growth functions typical of juveniles, and "an individual is at its most adult during that period of physiological reversal wherein the products of one growth phase are not added to but employed and consumed in ensuring the success of the next"[36]. In this sense migration is physiologically 'super-adult'. In that light it is equally understandable that the next most common stage at which migration differentiates is the first instar larva. This stage is better fitted than later larval instars, because it often has to travel farther than them at any rate when the eggs are not laid directly on the food, it is smaller and hence more buoyant, and more numerous.

At the same time the negative features of migration represent a differentiation in the direction of diapause. Diapause cannot be characterized by one physiological process in all insects. The one common feature is temporary failure to respond by further growth or development to the conditions that will, eventually, promote those processes[44]. Considered physiologically, migration is an example of this rather than an alternative to it.

During the depression of vegetative functions in both migration and diapause some other process occurs which is a pre-condition for their resumption. In diapause this unidentified other process is called "diapause development"[44]. In the winged aphid the equivalent of diapause development is promoted by an antagonistic process, locomotion, which restarts the arrested vegetative functions by central nervous induction[29]. This distinguishes a *locomotory* type of developmental arrest from other types, such as arrests of larval development that are broken by feeding, arrests of egg development or oviposition broken by copulation, and diapauses proper in which the nature of the response promoting diapause development is still unknown, but the stimuli are known to be low temperature or photoperiod[44]. By no means all the developmental arrests in migrants can be assumed to resemble the aphid's, for some are typical extended diapauses covering also periods of complete inactivity[4]. But in the common situation where the developmental arrest ends with the travelling, it is suggested as a working hypothesis that the two are causally related as in the aphid.

It follows from all this that when, as frequently happens, a deterioration in individual size, fecundity or other vegetative properties is observed under certain conditions, this should not be taken as wholly negative in effect until the possibility of an accompanying increase in migratory capacity has been excluded.

Ecological Functions of Straightened-out Movement

Resultantly downwind displacement independently of orientation was not recognized as a migratory "straightening-out" mechanism by Williams. But it also brings about long-distance travel, instead of confinement within a small area through frequent changes of direction, and does so on a larger scale than does oriented movement on or near the ground; and it results from the active, specialized behaviour of the insects. In locusts, aphids and many other insects[1,32] this consists in rising actively away from the ground and so out of what Taylor[18] calls the "boundary layer" within which non-migrants actively confine their movements. Such resultantly downwind travel cannot therefore be dismissed as the "passive distribution of individuals by overpowering forces", which Williams[2] excluded from migration. It can be assimilated readily into his definitions of migration cited in the first section above, provided we do not read into them his restrictions.

Moreover, these two mechanisms of straightening out, actively oriented and passively wind-borne, can be observed at different times in the same migrant, powerful locust and weak aphid alike. Migrants cannot therefore be separated into two classes according to which mechanism they exhibit, although they may differ in the relative importance of the two mechanisms in their migration. After their oriented ascent, aphids use the wind-borne mechanism in the earlier part and the low oriented one toward the end of a migration[19]. Garden chafer migrants seem to use the two more equally from the start[43]. According to the available accounts[2-4,21], many butterfly migrants keep close to the ground more persistently than aphids, chafers or locusts, and may thus use the oriented mechanism during a greater proportion of their time, although this does not necessarily mean for the greater part of the distance they travel.

Hitherto, it has been solely in the context of seasonal to-and-fro migrations between geographically discrete regions that the ecological function of straightening out seems to have been considered. Williams's hypothesis that straightening out is directionally adaptive, serving to direct the migrants to the right place at the right time, provided the motive for his successful search for evidence of return movements; and his hypothesis has now been confirmed for the seasonal movements of locusts by Rainey[16]. But the continued migratory movements of locust swarms through the mosaic of soils and vegetation within a wind convergence zone where suitable food plants and oviposition sites occur in patches are not directionally adaptive. Some long-range seasonal movements of aphids and other small plant-feeding insects seem to deliver them also to suitable breeding areas[44]. But again this is not true of their movements within very considerable regions wherein the host plant is not concentrated in one place but patchily distributed. Many sorts of habitat, hibernation site, etc., are similarly scattered.

In that situation migrants are no more likely to find what they require in one direction than in any other, or at one distance more than another. The straightening out of their movements has then no directionally adaptive significance. They travel in many directions by both straightening-out mechanisms; and this is adaptive inasmuch as some of them find the requirements in all directions and at all distances. Given enough individuals, the two mechanisms together make an efficient 'scanning' device that works on a coarse and a fine scale by means of long wind-borne, and short, low-level, oriented traverses, respectively.

Straightening out here serves the simpler and, presumably, more primitive function of displacement *per se*: the opposite of 'station keeping'. This is not, of course, an efficient procedure so far as the individual is concerned. The positive advantage of having large numbers of individuals if the migratory habit is to develop[19,26] is a point that has been little considered in discussions of the association between density and migration. Enormous losses of individuals *en route* certainly occur, and even entirely abortive movements by enormous numbers of individuals together, as in Elton's famous case of the lachnids on Spitsbergen. But these losses the species can evidently afford; and if migration tends to be associated with temporary habitats[32] this may mean that such habitats tend to permit higher multiplication-rates than permanent ones. The losses do not call in question the adaptive value of the behaviour pattern that brings them about because the same behaviour brings about biologically successful movements as well, with the added advantages of escape from overcrowding, enemies. etc. What the procedure does achieve is a very efficient coverage of the available habitats over a large area and avoidance of 'too many eggs in one basket'[19].

Given multi-directional movements between places arranged in mosaic the evolutionary problem of return movements disappears, as Wiltshire[26] pointed out in connexion with butterfly migrations. Many species of aphid alternate seasonally between woody and herbaceous plants. It has never been supposed that the descendants of a given individual necessarily returned to the same tree the same year. Nevertheless, untidy, constantly reshuffled returns are assumed, and no problem has been raised of how the migratory habit could persist in the population. The same applies to any insects that repeatedly disperse and colonize new habitats available at the time, new or old, so that no particular movement can be singled out as a return.

Movements of this kind are so common as to be of most interest to ecologists, but are included under dispersal rather than migration[9] because they are not directionally adaptive. Since that is a secondary matter it seems best to apply the term migration, as Johnson[1] and Southwood[32] are now in effect doing, to all cases where a change of location can be shown to be an active 'evolved adaptation' along the lines distinguished here, regardless of exactly how or at what stage in the life-history it occurs. The continued use of dispersal instead of migration for the particular mechanism of transport by wind or water can cause only confusion. Dispersal will, no doubt, continue to be used in the purely spatial sense of population scattering, especially when a loose term is needed because there is not yet enough information to judge whether the movement is migratory or not. If it is used in any more precise sense this should be specified. Thus dispersal is likely to be used for non-migratory movements involving no general inhibition of vegetative reflexes, but merely a change in them, as when the adult's food is different from the larva's; or for movements that may involve some temporary inhibition of them, as when new-hatched caterpillars scatter over a uniformly palatable leaf, but are not persistent or straightened out enough to rate as migration.

To sum up: recent work has undermined C. B. Williams's behavioural assumptions about insect migration while confirming his idea that it is a differentiated biological process. Migration is a persistent, straightened-out movement with some internal inhibition of the responses that will eventually arrest it. It may be effected by the insect's own locomotory exertions or by its active embarkment on some transporting vehicle. These are the behavioural aspects of a physiological syndrome which is 'super-adult' in character but may develop at any stage of the life-history, and in common with diapause involves a phase of depression of 'vegetative' (growth-promoting) functions as a condition for their resumption.

Grateful acknowledgment is made to Drs. A. D. Lees, P. E. Madge, T. R. E. Southwood and B. P. Uvarov, and to Prof. V. B. Wigglesworth, for their criticisms of this article in draft.

FLUCTUATIONS IN EQUATORIAL STRATOSPHERIC WINDS

By R. A. EBDON and R. G. VERYARD

Meteorological Office, Air Ministry, Harrow, Middlesex

THE predominance and persistence of easterly winds, especially above the level of the tropopause, is a well-known feature of the airflow over equatorial regions. This could be attributed to an inflow of air towards the equator; air moving towards the equator tends to retain the angular momentum about the Earth's axis which it possesses as a result of the Earth's rotation, and it therefore tends to arrive at the equator as an easterly wind. But westerly winds, that is, air moving faster than the equator, can also be produced over equatorial regions if there is a pressure gradient along the equator. However, as the net pressure gradient around the equator must be zero, a predominance of westerly winds is not to be expected; indeed, a westerly airflow encircling the equator is very difficult to explain. That there are, in fact, westerly air-streams at certain levels over some equatorial regions has been known for some time.

There are, for example, the large-scale westerlies in the lower troposphere associated with the flow patterns of the monsoons; but these are not surprising because of the substantial pressure gradients in the monsoon regions. But an explanation in terms of the pressure pattern of the occurrence of quasi-permanent westerlies in the equatorial stratosphere, sometimes called the 'Berson' westerlies (because it was A. Berson who first directed attention to the existence at about 20 km. of a narrow belt of westerly winds in the lower stratosphere over central Africa), has not proved practicable.

Moreover, it has been alleged by some workers that the Berson westerlies constitute a narrow ribbon of west winds extending right round the equator, and, as indicated above, this presents a challenge to dynamical meteorology. However, the idea which has been given in many meteorological publications, that the equatorial stratospheric westerlies occur with a regularity and persistence comparable to that of the equatorial tropospheric easterlies, needs some modification. Indeed, it would appear that in the lower equatorial stratosphere the zonal component of the wind, that is, both the easterlies and the westerlies, is subject to marked fluctuations—one regime replacing the other at intervals of a year or more[1-3]. Not only do data (based on radar wind ascents reaching 50 mb. and above) indicate that, for some months, there can be very considerable variations in the equatorial stratospheric winds between one year and the next, but they also show that westerly winds can occur not merely in a shallow layer but also throughout the

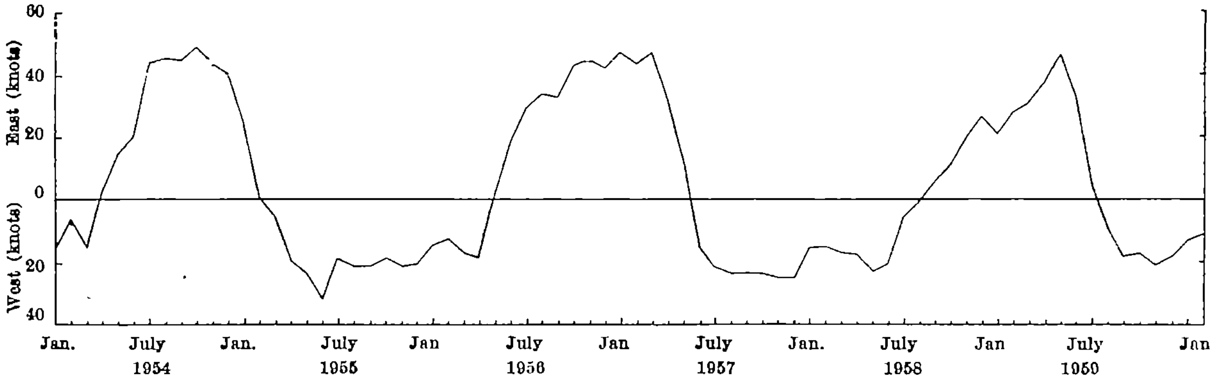

Fig. 1. Monthly mean values of 50-mb zonal wind component at Canton Island

lower stratosphere from the tropopause upwards to above 30 mb.

The monthly mean values of the zonal wind components at 50 mb. for Canton Island (02° 46′ S., 171° 43′ W.) for the period January 1954–February 1960 are shown in Fig. 1. It will be seen that there is a fluctuation with a period of about 25–27 months. Although only a few years data are available for analysis, this fluctuation is also evident in Fig. 2, which gives a curve of the monthly mean values of the zonal wind component at 60 mb. at Nairobi (01° 18′ S., 36° 45′ E.) and in Fig. 3 giving similar curves at 30, 40, 50 and 60 mb. for Christmas Island (02° 00′ N., 157° 23′ W.). At these stratospheric levels the wind direction at the stations considered is nearly always either almost due easterly or almost due westerly, except during the months when the change-over from one regime to another occurs. Once a predominantly easterly or westerly flow is established it tends to persist for some 10–13 months, although in any one month there may be a few days when the direction is reversed. The in-phase agreement between the 60-mb. curves for Nairobi and Christmas Island is quite remarkable. Similar results have been obtained for the zonal winds at 60,000 ft. (about 65 mb.) for the period 1954–60 at Singapore (01° 20′ N., 103° 53′ E.); and shorter period data for the 50-mb. level at Recife (08° S. 35° 53′ W.) show that the phenomenon also occurs at that station. Indeed, the evidence suggests that the fluctuation occurs more or less simultaneously at the same level all round the equator. In any event, the results indicate that, in the equatorial belt, a mean monthly (or yearly) wind obtained by averaging over a period of years will be very misleading if regarded as representative of the average wind in any particular month (or year), as is commonly done in climatology.

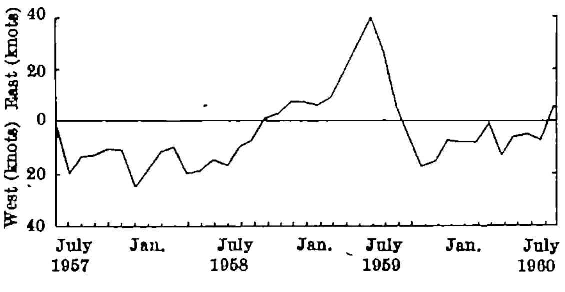

Fig. 2. Monthly mean values of 60-mb. zonal wind component at Nairobi

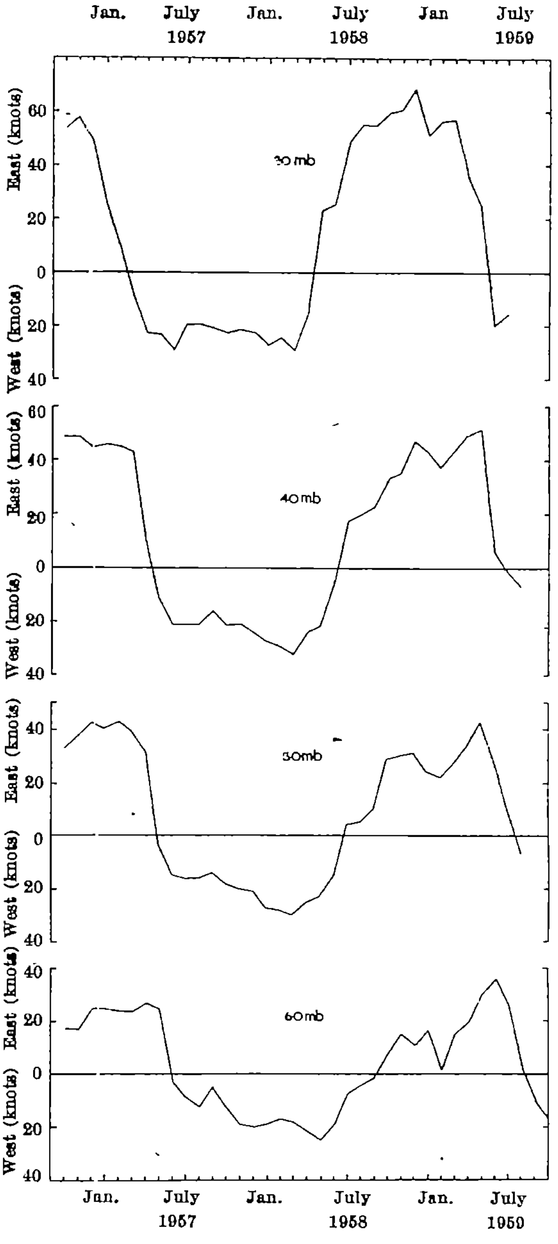

Fig. 3. Monthly mean values of zonal wind component at Christmas Island at 30 mb., 40 mb., 50 mb. and 60 mb.

Table 1. MONTHS DURING WHICH THE MEAN ZONAL WIND COMPONENT AT CHRISTMAS ISLAND CHANGED SIGN

Level	From east to west	From west to east	From east to west
10 mb.		(Oct. 1957)–(Nov. 1957)	
20 mb.	Oct. 1956–Nov. 1956	(Dec. 1957)–(Jan. 1958)	
25 mb.	Dec. 1956–Jan. 1957	Mar. 1958–Apr. 1958	Apr. 1959–May 1959
30 mb.	Feb. 1957–Mar. 1957	Apr. 1958–May 1958	May 1959–June 1959
40 mb.	Apr. 1957–May 1957	June 1958–July 1958	June 1959–July 1959
50 mb.	Apr. 1957–May 1957	June 1958–July 1958	July 1959–Aug. 1959
60 mb.	May 1957–June 1957	Sept. 1958–Oct. 1958	Aug. 1959–Sept. 1959

Table 1 shows the months during which the mean zonal wind component at levels above 60 mb. at Christmas Island changed from easterly to westerly or vice versa. (The two bracketed entries are based on the maximum winds reported, as insufficient data were available to give monthly mean values.) It will be seen that, as was found by Viezee[2], the change in wind direction occurs first in the higher stratosphere and then gradually descends. The one occasion when it was possible to detect the change at 10 mb. suggests that it takes almost a year before the change in wind direction at 10 mb. reaches 60 mb. When the change in wind direction occurs at 25 mb. it is some 6 months later before the corresponding change occurs at 60 mb. The curves in Fig. 2 show that the amplitude of the fluctuation decreases downwards.

From such investigations as have been possible with the data available there was no detectable connexion between these events in the equatorial stratosphere and events in the equatorial troposphere. If adequate data are available, it is hoped to determine the extent to which the fluctuation extends north and south of the equator. Results so far obtained suggest that within 10° the fluctuation still exists but with decreased amplitude.

This communication is published by permission of the Director General of the Meteorological Office, and the subject is discussed in detail in a paper which will be published elsewhere.

NEWS and VIEWS

Mineralogy and Petrology at Cambridge :

Prof. C. E. Tilley, F.R.S.

PROF. C. E. TILLEY is retiring from the professorship of mineralogy and petrology in the University of Cambridge at the end of the present academical year. On the retirement of Prof. Hutchinson and of Dr. Harker in 1931, the professorship of mineralogy and the readership in petrology were combined in a new chair of mineralogy and petrology, of which Prof. Tilley was the first holder. During his tenure of thirty years he has not only been exceptionally active in research, but also has been the leader in building a department of world-wide influence in its field. In addition to teaching and research in mineralogy and petrology, the Department has contributed much to the teaching of crystallography and to the crystallographic study of minerals. Prof. Tilley has played a full part in university life, having served on the Board of Research Studies, the General Board and the Council of the Senate. He was also for many years chairman of the Faculty Board of Physics and Chemistry, and was vice-master of Emmanuel College from 1952 until 1958.

Prof. W. A. Deer

PROF. W. A. DEER, who has been appointed to succeed Prof. Tilley, has held the chair of geology in the University of Manchester for eleven years. He has brought into existence there a thriving research school, the distinctive feature of which is the application of modern physico-chemical techniques to the solution of geological problems. In 1953, together with Prof. L. R. Wager, of the University of Oxford, he led a geological expedition to East Greenland, continuing investigations which had been interrupted by the Second World War. He has since directed various mineralogical researches on the rocks of the Cape Edvard Holm area, most of them still unpublished, but all of the high standard that has always characterized his work. Of recent years, he has spent much time writing a new book on rock-forming minerals in association with two members of the Manchester staff, Dr. R. A. Howie and Dr. J. Zussman. Active as he has been in geological work, Prof. Deer has found time to play an ever-increasing part in general university affairs. He has been chairman of the Executive Committee of the General Board of Faculties, and of the Science and Technology Section, and has served on committees too numerous to mention here. Particular reference should, however, be made to his work in the implementation of the extensive building programme on which the University of Manchester is now engaged.

British Drop Forging Research Association :

Mr. P. H. R. Lane

MR. P. H. R. LANE, head of the Members' Service Department of the British Welding Research Association, has been appointed the first director of research of the Drop Forging Research Association. Mr. Lane was educated at Alleyn's School, Dulwich, and Strand School, Elm Park. He obtained an honours degree in metallurgy at the University of London and afterwards joined the staff of the British Welding Research Association. He was first engaged in metallurgical work on the weldability of low-alloy high-tensile steels. In 1950, he transferred to the engineering section to work on the design of pressure vessels and pipe-line components, and for five years was in charge of the department dealing with this work. During this period he was also associated with work on the brittle fracture of steel plates and on the fatigue strength of welded components. In 1957, he returned to metallurgical work as deputy chief metallurgist of the Association, in charge of all ferrous metallurgical investigations. In 1959, he was appointed to the new position of head of the Members' Service Department, which is responsible for all contacts with the members of the Association. Mr. Lane is an associate of the Institution of Metallurgists, and an associate member of the Institute of Welding. He has published many papers on both the metallurgical and engineering aspects of welded fabrications and also on the techniques of experimental stress analysis.

The Mellon Institute: Research Directors

Drs. A. A. Bothner-By, Thomas G. Fox and Harold P. Klug have been appointed research directors in the Mellon Institute, Pittsburgh. Dr. Bothner-By joined the Institute in 1958 as a Staff Fellow and has been an assistant director of research since 1959. He is recognized as an authority on the use of nuclear magnetic resonance in organic chemistry, and has developed a centre of research in the latter field at the Institute. Dr. Fox joined the Mellon Institute in 1957 as an assistant director of research and has headed a large part of the Institute's extensive polymer research programme. He is known for his work in the chemistry and physics of rubber and other polymers. Dr. Klug joined the Institute in 1945 as an Administrative Fellow after eighteen years as a professor of chemistry in various universities. He became an assistant director of research in 1959. A specialist in structural physical chemistry, Dr. Klug is the author of two books and numerous papers.

Cultural Contacts in the British Commonwealth

Replying to questions in the House of Commons on March 2, Mr. D. Sandys, Secretary of State for Commonwealth Relations, said that the Government wishes to encourage the development of closer links between young people in the Commonwealth, and, besides initiating a programme for providing 5,000 additional places for overseas students in hostels where they will live and mix with British students, it proposes also to provide a number of new or enlarged social and cultural centres to be run by the British Council. The Government is prepared to meet the capital expenditure involved up to a maximum of £3 million, and will, as at present, consider applications for financial assistance to voluntary bodies concerned with Commonwealth youth. It is hoped, however, that private support will also be forthcoming for such projects and that the voluntary organizations active in this field would bear some share of the cost. Mr. Sandys expressed the Government's appreciation of the work of Field Marshal Sir Gerald Templer's Committee on this question. He said that the Government would welcome any reciprocal action in this sense among Commonwealth countries, and that the British Council had been authorized to consult voluntary organizations, the universities and other educational authorities and institutions about the whole programme. He undertook to see that the nature of the scheme was made widely known throughout the Commonwealth.

The Dounreay Fast Reactor

In written replies to questions in the House of Commons on February 28 about the Dounreay fast reactor, the Parliamentary Secretary for Science, Mr. D. Freeth, said that the work at Dounreay, though widely diversified, is concerned mainly with developing the fast reactor system. Construction of the fast reactor was completed during 1959 and a series of low-power tests have been completed; tests in the megawatt range will shortly begin. The reactor will then be gradually worked up to full power. The reactor first went critical in November 1959, and the main problems encountered since have not been concerned with the nuclear side of the experiment. No major change in the level of work at Dounreay is contemplated. Mr. Freeth also said that he hoped to make a statement shortly about a low-power nuclear reactor for the universities and colleges of technology.

Scientific and Technical Personnel in American Industry

A survey of the employment of scientific and technical personnel in private industry in the United States in January 1959 was conducted for the National Science Foundation by the Bureau of Labour Statistics of the Department of Labour as part of a comprehensive programme of studies of scientific and technical personnel in all sectors of the economy (Pp. vi + 66. Washington, D.C.: Government Printing Office, 1960. 45 cents). Estimates showed that of 800,000 scientists and engineers employed in American industry in January 1959. 764,000 were employed by the 47,500 firms covered by the survey. Engineers numbered 615,000 or 80 per cent, and the 149,000 scientists included 72,000 chemists, 18,000 biologists, 15,000 physicists and 15,000 geo-scientists. Aircraft, electrical equipment, chemicals and machinery accounted for 45 per cent of the scientists and engineers covered by the survey; but in the industries covered scientists and engineers represented only about 3 per cent of the employees, varying from 11 per cent in aircraft manufacturing to 0·3 per cent in textiles and apparel. In manufacturing industries, firms with 5,000 or more employees accounted for nearly two-thirds of the scientists and engineers, but only two-fifths of the total labour force. Of the 277,000 scientists and engineers employed in research and development. about 5 per cent were employed in administration; 235,000 were employed full-time in research and development, the remaining 40,000 being engaged also to a significant extent in other activities. Only in production and operational work were more scientists and engineers employed than in research and development, inspection quality control, or other production and operational work accounting for 39 per cent of the total. Almost 550,000 technicians, or about 72 for every hundred scientists and engineers, were also employed, and of these about 250,000 were classified as engineering and physical science technicians, more than 195,000 as draughtsmen, and 16,000 as medical, agricultural and biological technicians. In research and development about 156,000 technicians were employed, or 56 per 100 scientists or engineers. A comparison with previous surveys indicates that the employment of scientists and engineers grew much less in the years immediately prior to 1959 than in 1954–57, and even in research and development the rate of increase decreased from 13 per cent per annum between 1954 and 1957 to 7 per cent between 1957 and 1959; the increase being largest with mathematicians (17 per cent) and smallest for chemists (3 per cent).

Research in Biochemistry and Allied Sciences in Great Britain

At the Cardiff meeting of the British Association for the Advancement of Science in September 1960, a discussion was held, under the joint auspices of the Biochemical Society and Section I (Physiology and Biochemistry) of the Association, to consider the financing of biochemical research in Britain (see *Nature*, 188, 194; 1960). Because of their wide interest, the Biochemical Society has now published the proceedings of this meeting (*The Organization and Financing of Research in Biochemistry and Allied Sciences in Great Britain.* Edited by K. S. Dodgson. Pp. 51. London: The Biochemical Society, 1960. 2*s*. 6*d*.). Nine speakers were chosen, who were particularly concerned with the organizing and financing of biochemical research in Britain. After an introduction by Prof. A. Haddow, the role of the following organizations was described: Medical Research Council (Dr. F. J. C. Herrald), Agricultural Research Council (Sir William Slater), Department of Scientific and Industrial Research (Mr. C. Jolliffe), and the Imperial Cancer Research Fund (Dr. G. F. Marrian). Prof. F. C. Happold discussed problems of a university department of biochemistry, Dr. F. A. Robinson dealt with biochemical research in industry, and Dr. J. B. Bateman discussed American support of biochemical research in Great Britain. Prof. A. Neuberger summarized the proceedings of the meeting.

The Commonwealth Forestry Bureau, Oxford

THE work of the Commonwealth Forestry Bureau at Oxford has been described and published as an example of the work done by the Commonwealth Agricultural Bureaux, of which it is the youngest member (*A Synopsis of the Work and Growth of the Commonwealth Forestry Bureau, Oxford, 1939–1959.* Pp. 27. Oxford: Commonwealth Forestry Bureau, 1960. 2*s*. 6*d*.). The Bureau was formed in 1939 to serve foresters, wood technologists and scientists in associated fields throughout the Commonwealth, but from the first the quarterly publication, *Forestry Abstracts*, attracted subscriptions from foreign countries, and the Bureau and its periodical are now internationally known; the abstracts reach more than ninety countries. The principal work of the Bureau is the quarterly publication of *Forestry Abstracts*, which notices, by abstract or by title only, more than 5,000 publications annually on forestry and associated subjects.

Medicine and Public Health in China

IN a paper presented at the meeting of the American Association for the Advancement of Science on December 27, Dr. William Y. Chen, U.S. Public Health Service, discussed the condition of medicine and public health in modern China. The main sources of information for the preparation of the paper were various medical and public health journals published both in Chinese and English during the past ten years. The picture is presented against the background of medicine and public health in pre-Communist China, and shows that the most remarkable accomplishment has been the prevention and control of many infectious and parasitic diseases which have ravaged the country for generations. There has also been an improvement in medical education in quantity if not in quality. Other progress in medicine does not seem to correspond with the claims made for it.

Problems in Cybernetics

A VALUABLE new addition to the steadily growing list of translated Russian scientific journals has recently appeared; it is called *Problems in Cybernetics* (Pergamon Press. Pp. x+314. Russian editor, A. A. Lyapunov), and it is to be published at irregular intervals. The first issue contains a general article by Lyapunov, entitled "Certain General Problems in Cybernetics", which serves to show just what fields of inquiry the Russians include under the term 'cybernetics' at present (for the boundaries are very nebulous). Particular emphasis seems to be placed on automatic computer programming, for the simulation of all types of control process, including those analogous to certain biological processes; on representation of information and its processing, including that in automatic programme-controlled computers; on mechanization of various thought-like processes, as in decision making, recognition, strategy and various 'goal-seeking' operations. It is planned that the journal will contain, in the future, articles dealing with the theory of algorithms and automatic devices, theory of control and problems of production automation, theory of operations and of calculating machines, and with certain applications of the ideas of cybernetics to biology, economics and linguistics. Also, material will be included of a critical, bibliographical and historical nature, being primarily details of the work of the cybernetics seminar held in the University of Moscow. Particular reference is made to this seminar, which has been held since 1955, with a list of titles of papers; these include work on conditioned reflexes primarily. There are also listed titles of papers read at a technical conference held in 1957 which suggest wider fields of interest; especially applications to linguistics, to automatic translation, to coding of chemical formulæ, to speech analysis, to machine-reading, together with many technological aspects of computer design.

The Association of Universities of the British Commonwealth

THE report of the Executive Council of the Association of Universities of the British Commonwealth for the year ended July 31, 1960, records a membership of 103 universities, 17 university colleges and 4 other approved institutions of higher learning (Pp. 30. London: Association of Universities of the British Commonwealth, 1960). The volume of appointments work continued to increase, and, in one way or another, the Association helped with 877 vacant posts and dealt, mainly by correspondence, with 4,782 inquiries; 1,514 applications were received and the universities announced the appointment of 139 of the candidates who applied through the Association; of these 72 were in Australia, 28 in New Zealand and 20 in Hong Kong. Some account is given of the Association's work under the Commonwealth Scholarship and Fellowship Plan, and of its administration of the Frank Knox Memorial fellowships, the Marshall scholarships, the Imperial Relations Trust scholarships and of the Commonwealth University Interchange, as, for example, in connexion with the new scholarship scheme of the Drapers' Company to enable British schoolboys to take their first degrees at certain overseas Commonwealth universities. Some account of the work of the Committee of Vice-Chancellors and Principals of the Universities of the United Kingdom is appended, together with the accounts of the Association, and a note on the financial statement which records total expenditure of £48,089 and income of £52,187.

The Transvaal Museum

At the present time, museums are extending their ancillary services in many directions while still maintaining their essential function of the collection and preservation of objects. It is interesting to note in this connexion that the Transvaal Museum is sponsoring a bat banding project to serve as an aid in the study of these animals (*Bulletin Transvaal Museum*, No. 5. Pp. 8. July 1960). At present the emphasis is on cave bats and species of the genera *Rhinolophus*, *Miniopterus* and *Myotis* are being dealt with, though house bats such as Tadaridae have also been banded. While most of the work is at present concentrated on the Transvaal, banding in Bechuanaland and Natal has also been carried out. Bats have been recaptured over a maximum period of nearly two years and over the longest distance of about 100 miles. Chameleons have been kept in the museum for the purpose of studying behaviour and the flap-necked, dwarf, forest and horned chameleons have been included in this research. Particular attention has been given to a comparison of the aspects of behaviour in related species and genera.

National Museum of Wales

The fifty-third annual report of the National Museum of Wales for the year ended August 1960 records the welcome grant to the Welsh Folk Museum of £10,000 towards the cost of constructing a new car park and ticket office and for widening the approach road to the new entrance (Pp. 78+4 plates. Cardiff: National Museum of Wales, 1960). In the Department of Geology the systematic and stratigraphical fossil collections have been re-housed, and the model of the Penrhyn Slate quarry and collection of miners' lamps transferred to the new Industry Gallery. The artist in the Department of Botany has made models of 23 flowering plants, all of which replace the less attractive dried material previously on show. In the Glanely Gallery, Department of Zoology, the exhibit of birds' nests and eggs has been reorganized and augmented, and casts have been used to replace spirit specimens. In the Department of Archæology notable progress has been made in modernizing the Roman Gallery, and a careful watch has been maintained for chance discoveries. The Department of Industry was officially opened in May 1960, which event naturally culminated a year of preparation. The Department of Art has been much engaged in the work associated with temporary exhibitions. In this short note it is only possible to mention the highlights in the work of this progressive and stimulating museum.

Nomenclature of Human Chromosomes

The rapid growth of knowledge of human chromosomes and their importance in genetics and medicine have led to some confusion about nomenclature in the literature. Consequently a small study group of workers recently met in Denver, Colorado, to formulate an acceptable scheme of nomenclature (*J. Hered.*, 51, 214; 1960). It was agreed to number the chromosomes serially, from 1 to 22, as nearly as possible in descending order of length; that the sex chromosomes should continue to be referred to as X and Y, and that the 22 autosomes should be classified into 7 groups, distinction between which can readily be made. Within these groups, especially that comprising chromosomes 6 to 12, and including also the X-chromosome, identification of the chromosomes is difficult by present criteria, though it is believed that with very favourable preparations all or most of the chromosomes can be identified. Two valuable suggestions emerged from the discussions. One concerned the storage of documentation for reference, perhaps in a central repository; the other referred to the need to preserve cultures for future reference, comparison and exchange.

Studentships and Fellowships in Agriculture

The Agricultural Research Council has issued a useful booklet giving particulars of the thirty postgraduate studentships offered in 1961, tenable for one to three years, and including a limited number of veterinary training grants, of four years duration, given to enable science graduates to read for a veterinary qualification (Pp. 20. London: Agricultural Research Council, 1961). The studentships, which are open to honours graduates in science or those holding a veterinary qualification, or to graduates in agriculture or horticulture who have shown special interests in one of the basic sciences, and veterinary training grants vary from £340 to £520 per annum tax free, together with educational fees. Particulars are also given of three agricultural research fellowships of £700 to £1,000 per annum, tenable for up to three years, offered to honours graduates of not less than three years postgraduate experience, and two veterinary research fellowships of £900, rising to £1,000 per annum, tenable for up to three years, open to qualified veterinary workers with not less than three years experience in veterinary research. The booklet also describes the scope of agricultural research and outlines the openings available to agricultural research and advisory work.

Biographical Material relating to Richard Owen

Prof. Jacob W. Gruber, associate professor of anthropology, Temple University, Philadelphia, Penn., U.S.A., writes: "During the past few months, I have been preparing a catalogue of the collection of Owen correspondence in the possession of the British Museum (Natural History). It has occurred to me that it would be valuable to bring together as many materials relating to the life of Richard Owen as may still be extant. I would, therefore, appreciate any information relating to the nature and whereabouts of such materials".

The Indian Society of Genetics and Plant Breeding

The following have been elected officers and councillors of the Indian Society of Genetics and Plant Breeding: *President*, Dr. E. K. Janaki Ammal; *Vice-presidents*, Dr. A. R. Gopal-Ayengar, Dr. A. B. Joshi; *Secretary*, Dr. M. S. Swaminathan; *Editor*, Dr. B. P. Pal; *Councillors*, Dr. S. M. Sikka, Dr. S. Govindaswamy, Prof. P. N. Bhaduri, Dr. B. S. Kadam, Shri G. P. Argikar, Dr. K. Ramiah.

Royal Society Visiting Professorship

The Council of the Royal Society has appointed Prof. R. Couteaux, professor of animal biology, University of Paris, to be Royal Society visiting professor for the academic year 1961–62. He is expected to take up the appointment on October 1 and work in the Department of Biophysics at University College, London, on the structure and function of neuro-muscular connexions. Prof. Couteaux is a distinguished histologist who has made outstanding contributions by microscopic and histochemical means to our knowledge of synaptic structures.

University News: Birmingham

The title of first assistant to the chair of pathology has been conferred on Dr. D. B. Brewer, reader in pathology. The following appointments have been made: Dr. M. Z. Atassi, to be Research Fellow in the Department of Chemistry; Dr. D. A. Smith, to be lecturer in the Department of Microbiology; M. J. Hamlin, to be lecturer in the Department of Civil Engineering; Dr. B. Cockayne, to be lecturer in the Department of Physical Metallurgy.

The thirty-first annual report of the University of Birmingham Research Committee covers the session 1959–60 (Pp. 137+1 plate. Birmingham: The University, 1961). Besides summarizing research progress in the various departments during the session, it gives, arranged by departments under faculties, particulars of work published during the year and titles of theses approved for higher degrees. There is also a selected list of general works and writings by members of the University staff, not included in the departmental research bibliographies; this is arranged by faculty.

Cardiff

It has been announced that Dr. H. K. M. Lloyd, at present senior lecturer in metallurgy at the University of Nottingham, has been appointed to succeed Prof. W. R. D. Jones in the chair of metallurgy at the University College of South Wales and Monmouthshire, Cardiff.

London

Dr. R. A. Shooter, reader in bacteriology at St. Bartholomew's Hospital Medical College, has been appointed to the chair of bacteriology tenable at that College. Mr. L. H. Hamlyn, lecturer at University College, has been appointed to the University readership in histology tenable at that College. The title of reader in physics in the University of London has been conferred on Dr. R. O. Davies in respect of his post at Queen Mary College.

Manchester

Prof. B. H. Flowers, who has held the chair of theoretical physics since 1958, has been granted the title of Langworthy professor of physics, and will continue to be responsible for the teaching and research in theoretical physics. Two other chairs in physics, one vacated by Prof. Samuel Devons and one recently authorized, have been filled by the appointments of Dr. E. B. Paul (from a date to be arranged) and of Dr. H. E. Hall (from March 1). The following appointments have also been announced: Dr. J. Hoenig, to be reader in psychiatry; Dr. M. F. Lappert, to be senior lecturer in chemistry. Dr. J. F. Adams has been appointed a reader in mathematics from a date to be arranged.

Announcements

Prof. C. H. Townes, professor of physics at Columbia University, has been awarded the Rumford Premium of the American Academy of Arts and Sciences for his work on microwave amplification by stimulated emission of radiation (maser). The award consists of two medals, one of gold and the other of silver, and 5,000 dollars.

Lord Nelson of Stafford has been elected an honorary member of the Institution of Electrical Engineers in recognition of his contributions to the development of electrical science and engineering, and for his services to the Institution.

Julius A. Stratton, president of the Massachusetts Institute of Technology, has been awarded the Faraday Medal of the Institution of Electrical Engineers for his contributions in the fields of technological education and research in radio communication.

Mr. P. Lambert has been appointed head of the Engineering Section of the British Steel Castings Research Association, Sheffield. Mr. Lambert joined the Association's staff in September 1955, as a senior investigator in the Plant Engineering Section, paying special attention to problems arising in fettling shop operations. During the past year he has been engaged on liaison work with member companies relating to the simplification of work.

The annual conference of the Institute of Metal Finishing (incorporating the Electrodepositors' Technical Society) is to be held at Llandudno during May 2–6. Further information can be obtained from the Conference Secretary, Institute of Metal Finishing, 32 Great Ormond Street, London, W.C.1.

A meteorological field course is being organized jointly by the Royal Meteorological Society and the Field Studies Council, and is to be held at Preston Montford during April 5–12. The course is particularly designed for sixth-form grammar school pupils. Further information can be obtained from the Assistant Secretary, Royal Meteorological Society, 49 Cromwell Road, London, S.W.7.

The spring conference of the X-ray Analysis Group of the Institute of Physics and the Physical Society, entitled "The Crystal Structures of Organic Compounds", will be held in the Chemistry Department, University of Glasgow, during April 6–7. Further information can be obtained from the Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

An international symposium on "Criticality Control in Chemical and Metallurgical Plant", organized by the Organization for European Economic Cooperation's European Nuclear Energy Agency in collaboration with Kernreaktor Bau- und Betriebsgesellschaft m.b.H., is to be held during May 2–5 at the Karlsruhe Nuclear Research Centre in Germany. Further information can be obtained from O.E.E.C. European Nuclear Energy Agency, 38 Boulevard Suchet, Paris 16e.

The fifth European Congress on Molecular Spectroscopy is to be held in Amsterdam during May 29–June 3. The Congress is being sponsored by the International Union of Pure and Applied Chemistry, the Koninklijke Nederlandse Chemische Vereniging and the Nederlandse Natuurkundige Vereniging. Further information can be obtained from Dr. D. H. Zijp, Anorganisch Chemisch Laboratorium, Nieuwe Achtergracht 123, Amsterdam-C, Netherlands.

Erratum. The recent announcement concerning Dr. D. C. Rose in these pages (*Nature*, 189, 444; 1961) is incorrect; Dr. Rose has in fact been appointed associate director of the Division of Pure Physics of the National Research Council, Canada.

THE NATURE CONSERVANCY

ANNUAL REPORT

THE eleventh annual report of the Nature Conservancy, covering the year ended September 30, 1960*, records a number of encouraging features to which reference is made on p. 779. Planning and initiating scientific management on the national reserves continued to be a major activity and the six new management plans approved by the Conservancy during the year brought the total of reserves managed under plans to 39, or nearly half the total declared. In Scotland 16 out of 24 declared reserves are now managed under approved plans; in England 19 out of 42; and in Wales 4 out of 17. High priority was given to increasing the cadre of field-staff such as warden naturalists, wardens and estate workers, but outside assistance is still needed. Another major task of the conservation staff is concerned with the sites of special scientific interest, and in England and Wales the revision of county schedules, timed to coincide with quinquennial revisions of county development plans, is now well advanced. Four new national Nature reserves were established during the year: 2 in Scotland, 1 in Wales and 1 in England. With 4 extensions, the 84 reserves at the end of September covered 138,991 acres.

During the year, 10 new grants for research, totalling £7,173, were approved, and 7 existing grants were extended or renewed, bringing the expenditure on grants to some £16,529 compared with £10,217 a year ago. Fourteen studentships were awarded, 20 were continued and 6 applications for third-year extensions were approved. Lists of these research grants and studentships, with lists of reserves, publications and of the Conservancy's committees are appended to the report. With special grants from the University Grants Committee, a one-year postgraduate diploma course in conservancy was set up at University College, London, and 6 additional studentship awards were made to enable the 6 students accepted to attend this course.

Scientific research again covered a wide field. At Merlewood Research Station, the major research continued to be on woodlands and particularly to elucidate as fully as possible the biological and physical processes in which the soils and living organisms of a woodland are involved, more especially the amounts of nutrients for plant-growth available in the soil, the rate at which they are taken up, and the processes by which the supply is maintained. An important part of the work in this field was carried out in three sets of forest plots, at West Tofts in the Breckland, Abbotswood in the Forest of Dean and at Bedgebury in Kent; and from the observations obtained it was possible to draw up a major part of the balance sheet for nutrients in the plots and to assess the productivity of the different tree species. These investigations show that losses of nutrients from the ecosystems of forest plots which are incurred by the felling and extraction of the stems are not so great as for agricultural crops, the most serious potential losses being those of phosphorus and calcium. Some badly needed information on the rate of supply of minerals by soil weathering and the rate of loss by leaching may in the future be acquired from the experimental plots at Gisburn Forest, set up jointly by the Forestry Commission and the Nature Conservancy. The present work of the Plant Soil Section is concentrated on the study of the nutrient cycles in irregular woodlands of semi-natural structure, and along with studies on breakdown of litter an extensive survey has been made of woodland soil animals. To facilitate comparisons of the nutrient cycles and productivities of natural and managed woodlands, an attempt is being made to provide samples of woodland resembling what is believed to be the natural state.

At Moor House, besides continued work on the productivity of grasslands and the growth of tree species in upland areas, a broad survey of the plant ecology of such areas was commenced and a geological survey, including a map of the reserve and an outline investigation of the peat stratigraphy and vegetation history, as shown by pollen analysis, is almost ready for publication. Investigations on the mountain grasslands and soils of Snowdonia also continued, and in the study of soils attention has been given to the distribution of iron within them, while work continued on the trace element content (particularly of cobalt and copper) of soils of direct interest to the research programme as a whole. Differential grazing experiments at Cwm Idwal and on the south-east slopes of Snowdon show that, with complete protection from grazing, *Calluna vulgaris*, *Vaccinium myrtillus* and *Erica tetralix* are increasing on the more acidic soils, and taller-growing grasses, such as *Deschampsia caespitosa* on the more basic sites, though, in such instances, some of the former groups of species are gaining a foothold. A detailed study has commenced of the connexion between the considerable differences in climate and vegetation within Scotland, and the work of re-establishing and encouraging the regeneration of woodlands on nature reserves in Scotland continued to expand. The latest evidence arising out of the work of recording of chalk grassland transects in southern England is that, despite control measures, rabbits have returned in such numbers on a few sites that their grazing is reversing the changes in vegetation.

Work on the ant population of east Dorset heathland at Furzebrook indicates that the effect of fire has been to destroy their population directly and indirectly in various ways, or that they are now spread more thinly over a greater area. Investigation of the food and population cycle of the short-tailed vole (*Microtus agrestis hirtus*) at the Carron Valley will be completed during the present year. A new Unit of Grouse and Moorland Ecology was set up in co-operation with the University of Aberdeen. The pilot red grouse inquiry financed by the Scottish Landowners' Federation indicated that grouse numbers are usually controlled by the birds themselves, and the main problem before the Unit is to discover how the limits to numbers are set. Ecological research on British reptiles continued at the Furzebrook Research Station, and the programmes of marking grey seal (*Halichoerus grypus*) pups on the Farne Islands, the Pembrokeshire coast and in the Hebrides have been more closely co-ordinated. An analysis of all results to date undertaken in consultation with the Zoological Society of London showed that the maximum period between the marking and the recovery of a seal is no more than 61 weeks.

---

* Report of the Nature Conservancy for the year ended 30th September, 1960. Pp. vii+138+14 plates. (London: H.M. Stationery Office, 1960.) 6s. 6d. net.

In coastal research, experimental studies at Orfordness demonstrated that the movement of beach material on any coast is not necessarily uni-directoral. The work at Newborough Warren, Anglesey, has now established that the continued mobility of the dunes produces a cyclic interchange between the marram grass community of the dunes and the creeping willow community of the slacks, which could have a period of about 80 years in parts of the dune system at Newborough, although the cycle may be interrupted or extended at any stage by associated changes in the surrounding dunes. The importance of climatological research is also stressed. The Climatological Section at Aviemore provides observations and advice for other research sections and for conservation and regional officers concerned with managing the reserves; and the Moor House Reserve is of exceptional interest as being possibly on the very threshold of climatic conditions suitable for blanket fog development and maintenance, and this and similar thresholds are to form a chief line of research in the Climatological Section.

As usual, the work of the Scientific Advisory Services has considerable scientific interest. In hydrology, the Conservancy has some small-scale experiments in progress which can be expected to contribute useful preliminary information on the effects of land management; but there is real need for field experiments on different catchment areas on a larger scale and by a specialized research unit. Formal representations were made to the Minister for Science regarding the risks to wild-life from toxic chemicals used in agriculture, and a Unit has been established to investigate the subject. The Conservancy also views with great concern the increasing disregard by highway authorities of Circular 718 relating to chemical spraying of roadside verges, and has made representations to the Ministry of Transport. The Conservancy also emphasizes the urgent need for continued forethought and action on the part of the fire service, railways, agriculture, the Nature Conservancy itself and tourism and others to initiate research into the causes of fires in forests, heaths and moors, and into the appliances and techniques for their prevention and control. Investigations into the heavy mortality among foxes suggests that seed dressing with dieldrin and similar chemicals may be a cause. An investigation is planned into the food of red deer, and the Conservancy has also stressed the need for a full scientific appraisal of the status of the coypu (*Myocaster coypus*) in Britain.

SELF-REGULATION IN LIVING SYSTEMS

A SYMPOSIUM on "Self-Regulation in Living Systems", organized by Dr. D. K. C. MacDonald, was held at the National Research Council in Ottawa on January 6. More than thirty people took part, and, as at previous meetings (*Nature*, 184, 239 (1959); 183, 370 (1959); 187, 298 (1960)), these represented many different scientific disciplines, including engineering, neurology, philosophy, physics and physiology. The five papers presented all provoked lively discussion.

In the morning Dr. Bernice Grafstein (McGill University, Montreal) first dealt with the reception of peripheral information, that is, how information is carried from the surface of the body to the central nervous system. By way of introduction, Dr. Grafstein described the structure of a sensory neurone, consisting essentially of a sensory nerve ending which receives the external impulse and a long fibre or 'axon' which transmits the signal to the central nervous system. The transmission takes place with finite velocity by means of progressive displacement of electrical charge through the membrane of the axon. This charge displacement involves essentially a positive feedback mechanism and the resulting 'action potential' is consequently an 'all-or-none' event. A neural message consists of a train of action potential pulses, the coding mechanism being the spacing between the pulses. There are different types of sensory endings sensitive to different stimuli, and there is an orderly spatial arrangement of terminations in the cerebral cortex corresponding to different parts of the body. Thus the central nervous system is informed about the nature and location of the stimulus by which nerves are stimulated. The main part of Dr. Grafstein's talk was concerned with the modulation of the pulse-train in relation to the strength and time-variation of the stimulus. Examples of records of action potentials were shown to illustrate that usually application of an external stimulus gives an initial rapid burst of activity followed by a slower steady activity. For many types of receptor it appears that the initial frequency of action potential activity is dependent on the rate of application of the stimulus, whereas the steady final level depends (often logarithmically) on the magnitude of the stimulus.

Dr. Grafstein considered in greater detail the case of the muscle spindle as a sense receptor. By inserting an electrode very close to the spindle (rather than merely measuring the action potential at a distance down the axon) one can measure a local steady potential at the receptor, the so-called generator potential. On application of the stimulus, this generator potential goes through an initial peak to a final maintained level, the initial peak being related to the rate of stretch of the muscle, and the maintained potential depending on the degree of stretch. There is a fair linear correlation between the final frequency of the action potential pulses and the final generator potential-level. Precisely how the stimulus is converted into a generator potential in the receptor is at present unknown. The generator potential signal is passed down the axon as a digitally coded (or perhaps better pulse-frequency modulated ?)

train of action potentials, and it appears that the message is integrated and reconverted into an amplitude-coded form in the central nervous system.

Dr. H. K. Hartline (Rockefeller Institute) then described measurements of the action potential in optical nerve fibres. In this case the receptor in the eye contains a protein substance which undergoes a reversible photochemical reaction on absorption of light. A generator potential is then produced (by an undiscovered mechanism) and the message is transmitted to the brain by action potentials in the optic pathway similar to those described above. In this case, the final rate of activity (after the initial burst) is correlated logarithmically with the brightness of incident light. Dr. Hartline's main thesis was to emphasize that data-processing starts right at the receptor and is not confined to the brain. The receptor passes on to the brain only information 'it considers relevant', and, to quote Dr. Hartline, this often involves a terrible distortion of truth, as it accentuates sudden changes occurring in time and space. Dr. Hartline described experiments on the horseshoe crab, the eye of which is a simple structure made up of a number of separate facets or elements. Electrodes are connected to one particular element of the eye so that the output of a single receptor can be measured. It is found that the output from nearby facets are not independent; for example, the response from a particular element decreases when a nearby element is illuminated. There is a linear relation between the decrease of frequency of one facet and the activity above a certain threshold value of another facet closer than a few millimetres. Dr. Hartline had some lantern demonstrations remarkable in their simplicity to show that this same 'distortion of truth' occurs in the human eye also; for example, a wedge the brightness of which as measured by a densitometer varies uniformly between a light and a dark background appears to have a light band just inside the light background and a dark band within the dark background. This to some extent gives the lie to the old adage that 'seeing is believing'.

In the afternoon Dr. Bradford Dunham (International Business Machines) discussed the computer itself as an object of scientific curiosity. He mentioned three ways of studying computers. The first is by formal studies as initiated by Turing thirty years ago; a Turing machine is a conceptual computer obeying a specific set of simple rules, and the object of the exercise is then to see how much the computer can accomplish. Turing's method appears of limited value; in particular, it is difficult to correlate formal studies with practical conditions. The second method of approach is to construct or simulate a 'baby' machine, a small computer with limited range, and to understand as fully as possible its mode of operation in its own little restricted world. The results are again often doubtful in application, as it is usually by no means certain whether particular conclusions are merely a specific consequence of smallness or whether they are indeed of wider validity. The third way of studying the potentialities of computers is to observe how a computer deals with a particular class of problems. Dr. Dunham described experiments made at International Business Machines to programme a computer to perform automatic design, amplifying what he had said at an earlier symposium (*Nature*, 184, 239; 1959). He pointed out analogies between the method followed by the machine and the nineteenth-century Darwinian theory of design by natural selection in many generations. Dr. Dunham remarked that the method has been used to design parts for a rocket mechanism, and a long discussion ensued.

The following paper was presented by Dr. Rolf Landauer (International Business Machines) on the necessity for friction in decision-making systems. Thermal agitation in a system has two related effects: friction or dissipation of energy, and random impulses or noise. Noise problems have been widely studied and Dr. Landauer considered an example in information theory. Loss of memory of a 'particle' in an information store takes place when thermal agitation is too large in comparison with the height of the potential barrier separating the two alternative positions for the particle. Dr. Landauer mentioned calculations to indicate what was the optimum size for an element in a memory store of given total mass. Most of Dr. Landauer's talk, however, was concerned with friction *per se*. Whenever we have an indistinguishable merging of two streams of particles there must be friction, for without friction the forces on the particles can be described by a field of force only, and this implies that the particle paths are reversible. However, as we wish to 'kill off' the past memory of the particle trajectories, the paths cannot be reversible and so we must have friction in the system. Dr. Landauer argued that if a machine is to make decisions it cannot be acting merely as a table of 'logarithms' in which every situation is allowed for by the designer, but it must contain some processes involving such an irreversible merging of two streams. The work of Szilard on the measuring process was also mentioned; in general, to make a meaningful measurement we must obtain a result independent of the past history of the measuring apparatus, and this necessitates friction in the system, as, for example, the damping of a galvanometer.

The final talk, by Dr. Arnold Burgen (McGill), described up-to-date knowledge of the problem of cellular storage of information. Information is stored in the nucleus of the cell in the compound deoxyribonucleic acid, a complex chain molecule made up of a large number of units or nucleotides. Dr. Burgen argued from chemical data that a simple molecular organism such as a so-called bacteriophage virus (the nucleus of which would contain only one or two molecules of deoxyribonucleic acid) required about 10^4 nucleotides, a cellular organism containing a single chromosome such as a complex bacterium required about 10^6, while the germ cell of a mammal needed about 10^{10} nucleotides. There are four different types of nucleotide which can be arranged in any order on the deoxyribonucleic acid spiral chain. We never find a single chain, but a chain is always accompanied by its complement. Thus an adenine unit on one chain is always cross-linked (by hydrogen bonding) to a thymine unit on the complementary chain, and a guanine unit to a cytosine. This double chain plays an important part in the replication process of the deoxyribonucleic acid and so of the genetic information when the cell divides. It appears that the double helix starts to split from one end and each parent helix then acts as a 'template' to synthesize two daughter helices complementary to the parents. Two separate double helices identical to the parent eventually emerge. This synthesis has recently been carried out in the test-tube, and the postulated mechanism shown to be essentially correct by labelling with tritium and nitrogen-15. Dr.

Burgen went on to discuss the details of how the genetic information was stored in deoxyribonucleic acid, suggesting that it was likely that four bases were needed to represent one piece of information. He finally considered some of the possible effects of a mistake in the replication process, that is, of a mutation. Dr. Burgen's overall aim was to show that there is no difficulty in principle of storing enough genetical and reproductive information in a mammalian germ cell.

A. M. GUÉNAULT

BIOGEOGRAPHY OF SOUTH-EAST AFRICA

A SYMPOSIUM on "The Biogeography of South-east Africa" was held at the University of Natal, Pietermaritzburg, during September 7–8, 1960, under the chairmanship of Prof. S. F. Bush. South-east Africa was taken to include Zululand, Natal and the eastern Cape Province. Particular attention was given to the coastal lowlands, and their affinities with East Africa, but a consideration of the more southern and upland communities made it necessary at times to expand the scope of the symposium to include the south-western Cape.

In south-east Africa the relief, which is in the form of a number of ascending steps, is such that, in general, the inland isotherms tend to run in a north–south direction, parallel to the coast (O. Williams). There is a pronounced difference in temperature between the hot eastern coastlands and the cooler interior highlands, and at the same time temperatures along the coast increase gradually northwards. The coastal plain to the north of Lake St. Lucia (28° S.) experiences a mean July (mid-winter month) temperature of more than 18° C., while areas lying above the 4,000 ft. (1,225 m.) contour experience a mean July temperature of less than 13° C.

Rainfall at the coast ranges from about 30 to 55 in. per annum, and is heaviest at the northern and southern districts of the area considered. Inland, on the seaward-facing escarpments, rainfall is about 70 in. per annum, but on the intervening surfaces it is considerably less. Most of the rainfall is received during summer, but this characteristic is far more pronounced inland than at the coast.

The vegetation of the north-eastern coastal plain is floristically of tropical African affinity (A. W. Bayer and C. J. Ward). Practically every tropical family is represented in northern Zululand, often by the same genera and species as in the tropics. In the case of cosmopolitan families, the Zululand genera are the same as, or closely related to, the tropical African genera. On the other hand, predominantly extra-tropical families are poorly represented in north-eastern Zululand.

The north-eastern vegetation is complex, being made up of a number of different ecological associations, which include mangrove forest, swamp forest, dune forest, coast forest, riverine woodland and savanna. In the region between about 27° 30′ and 29° S., but most noticeably in the Lake St. Lucia area (28° S.), there is a heavy subtraction of tropical species in every type of association. Of a representative 408 species of woody plants occurring in north-east Zululand, approximately 130 do not extend farther south of Lake St. Lucia. To the south of this area of marked thinning out, subtraction is more gradual, the truly tropical element in the flora finally disappearing to the south of East London (33° S.). The number of different plant associations also shows a decline to the south of 28° S.: the swamp forest association does not extend farther south of 30° 45′ S., and the mangrove association terminates at 32° 15′ S.

As the tropical flora becomes impoverished, it becomes admixed with a number of South African species which are not found in north-eastern Zululand.

Regarding sedges, the majority of water-loving species extend from the tropics (where they are distributed across the continent from west to east) through Mozambique and Southern Rhodesia, to the Transvaal, Natal and the Transkei to about 33° 30′ S. (K. D. Gordon–Gray). To the south there is a narrowing of the zone occupied by these plants, so that south of the Natal border only a coastal distribution pertains. In Natal, the majority of the species extend up the river valleys to the foothills of the Drakensberg, but do not appear to cross this mountain barrier into Basutoland and the Orange Free State.

The 'dry-land' sedges follow approximately the same distribution southward, except that they are limited to the drier, and sometimes the higher, land of Southern Rhodesia, and are probably not represented at all on the coastal plain of Mozambique. Annual species, which can more easily overcome the unfavourable season than can perennials, are more widespread from east to west, but they also do not usually extend farther south than 33° 30′ S.

Generally, it may be stated that in this southward 'funnelling' down of the tropical Cyperaceae, there is a marked decrease in the number of species, many tropical species not at present being known from farther south than the St. Lucia area. There is also a marked decrease in the variety of plant forms south of Lake St. Lucia, and a decrease in plant size and inflorescence branching, accompanied by an increase in tufting of the plants and in leaf-blade development.

A temperate sedge flora exists in the south-western area of the sub-continent. This flora extends northwards, particularly along the high ground, and intermingles with the tropical element in Natal. In addition, Natal has its own endemic species.

The freshwater fish fauna of south-east Africa appears to be a very recent fauna, possibly entirely post-Pleistocene, in marked contrast to the temperate fish fauna of the south-western Cape (R. S. Crass). The south-east African fish fauna is clearly tropical in its affinities. Nineteen of the 28 species which occur in the lower Pongolo River (27° S.) extend northwards at least to the Zambesi. Of the remaining 9, 5 are restricted to the eastern Transvaal and the Natal lowlands. These 10 forms may be considered sub-tropical, and are taxonomically closely related to species found farther north.

No strictly freshwater south-east African fish extends south of the Natal border, progressive impoverishment of the fauna occurring southwards. At family-level this trend is illustrated by the fact that out of 14 families found in the Zambesi, only 9 reach the Pongolo (27° S.), 4 the Tugela (29° 15′ S.), and 1 the Umtamvuna (Natal border). This impoverishment does not constitute a true subtraction of the tropical fauna southwards; it is more in the nature of a diffusion gradient which reflects the difficulty experienced by the recent fish fauna in moving southwards across divides between the west-to-east flowing rivers.

Only 13 species occur in the Natal highlands. Of these, 8 are tropical or sub-tropical species, while the remaining 5 may be regarded as temperate, since they are restricted to the cooler highlands. One of these is distributed from the eastern Transvaal to the main Cape watershed, but the others do not extend to the Cape.

The amphibian fauna of north-eastern Zululand is almost identical with that of the lower Zambesi-Beira area, both in its composition and in number of forms (J. C. Poynton). However, in the Lake St. Lucia area, the number of tropical forms drops from 35 to 15. Subtraction farther south is more gradual, but only one form reaches as far as Knysna (34° S.). This subtraction margin is best developed in the coastal lowlands: the tropical fauna becomes markedly thinned out as the land rises from the coast.

South of Lake St. Lucia, the fauna changes from an almost purely tropical to a heterogeneous assemblage, for those tropical forms which pass Lake St. Lucia become joined by a 'South African' fauna, made up partly of sub-tropical Natal-eastern Cape endemics, and partly by members of a temperate fauna[1] centred in the south-western Cape. The subtraction margin of this latter fauna is best developed in the highlands.

The natural distribution patterns of the higher vertebrates have been profoundly upset by human settlement and cultivation, but overall trends are still evident. The tropical element in the avian fauna of north-eastern Zululand is very conspicuous, but there is a marked subtraction of tropical forms in the region of Lake St. Lucia (J. Vincent). Of the 33 species which extend down into Zululand and Natal, but which have no sub-species resident farther south, 17 reach their southern limitation in the St. Lucia region. Elsewhere, subtraction is gradual, but none of these species at present occurs south of Durban.

The majority of tropical mammals occurring in southern Africa show a general distribution pattern which roughly coincides with savanna areas (J. A. Pringle). In the east, this distribution 'funnels down' and extends as a narrow strip along the coast from northern Natal to the south-western Cape. Subtraction of the tropical forms occurs along this 'funnel'. About half the tropical species of Chiroptera and Insectivora do not extend as far south as Natal, the reduction in the number of species apparently beginning in northern Mozambique. On the other hand, most of the Carnivora have a much wider range, and reach Natal. In each of these three groups, the number of tropical species shows a two-thirds reduction between St. Lucia and Port St. Johns (31° 38′ S.), and only a small number in each group extend as far as Cape Town.

The same tendency to 'funnel down' the south-eastern lowlands and extend to the south-western Cape is shown by the tropical rodents (D. H. S. Davis). A southward subtraction is shown in this area. A small 'southern African' element is also represented in this group.

Concerning invertebrates, it appears that the main route of migration from the African tropics is also down the eastern half of southern Africa, but this applies chiefly to groups which have strong and active members which are able to distribute themselves by their own bodily activities, and which are not particularly dependent on the humidity factor (R. F. Lawrence). The position with regard to the humidity-dependent groups is quite different, the tropical and South African faunas having little in common. In the harvest-spiders, for example, the dominant family in tropical Africa is not the dominant family in South Africa, and neither region has a single species of these families in common with the other. The dividing line is the Limpopo region. Again, the South African Onychophora have nothing in common with the tropics, where only one species of a quite different family occurs. In both the harvest-spiders and the Onychophora the relationships of the South African faunas with those of the other continents are greater than with those of the African tropics: their affinities are inter- rather than intra-continental, and latitudinal rather than longitudinal. The cryptic faunas with inter-continental relationships are older, probably very much older, than the groups with intra-continental relationships.

The southern African Diptera also show a marked differentiation into tropical and South African temperate assemblages (H. E. Paterson and B. Stuckenberg). The tropical families tend to funnel down the eastern lowlands, where progressive subtraction occurs. Very few tropical dipterans reach the south-western Cape. The dipteran fauna of the Natal highlands is largely continuous with that of the south-western Cape. This temperate fauna differs strikingly from the dipteran fauna of north-eastern Zululand. The relationships of the temperate fauna are again inter- rather than intra-continental, and latitudinal rather than longitudinal. Some very primitive forms are present in this south-western fauna.

All families of butterflies represented in south-east Africa have a predominance of species in the tropics (K. M. Pennington). Extension of tropical species into South Africa is via the east-coast route, although here the tropical fauna shows a pronounced tapering off. A non-tropical South African fauna is also represented in south-east Africa, particularly in the highlands, where close affinities with the fauna of the south-western Cape are shown.

North-eastern Zululand is very rich in tropical arthropod-borne viruses: in this region 11 viruses have been found to be active (P. Weinbren). From Lake Sibayi (27° 20′ S.) southwards, however, the general virus activity tails off abruptly, and there is evidence of only 3 of the above viruses in Natal. At Knysna, however, 6 of these viruses have been found, producing a pattern which is in contrast to the usual pattern of continued subtraction southwards.

Through the great diversity of groups considered at this symposium, a close conformity of distribution patterns seems unmistakable. The flora and fauna of the northern Zululand plain is truly tropical:

in the north-east, South Africa possesses an almost fully developed tropical East African association. However, in South Africa this association is very definitely restricted to a small area. A well-marked southern 'boundary' is evident in the region of Lake St. Lucia, there being a most pronounced subtraction of tropical species in this region. The factors causing this southward limitation have still to be clarified. The cause of the western limitation of the tropical assemblage inland is explainable in terms of physiography, the ascent to the central plateau causing profound changes in climate; but there are no comparable physiographical changes in the St. Lucia region. There are also no abrupt zonal climatic changes in this region, although it seems significant that the 18° C. mid-winter isotherm crosses the coastal plain in this region, after skirting the western edge of the Mozambique plain. This isotherm is used to divide a tropical from a non-tropical climate in Koppen's classification of climates[2]. Phytogeographical changes in this region are not in themselves sufficient to account for the general changes in the fauna, for although the taxonomic changes in the vegetation are extremely marked, the physiognomic characters of the various plant associations are not conspicuously altered.

Whatever the factors causing the biogeographical changes in Zululand may be, it is evident that the widely held belief that "There is a strong, general reduction of the (tropical) fauna northward into the Sahara and a less strong reduction and some differentiation southward into South Africa[3]" is a serious under-estimation of the extensiveness and importance of these changes. The south-east African plant and animal communities are evidently built up from three quite distinct elements: a tropical complex entering from the north, a warm temperate complex entering from the south-west, and a relatively small complex indigenous to the area. The area clearly shows the characteristics of a transition zone, and this symposium brought into particular prominence the fundamental difference between the flora and fauna of the African tropics and the flora and fauna centred in the south-western Cape. The recognition of the south-western Cape as a biogeographical region distinct from the Ethiopian region is indicated by all the groups which are less recent than the contemporary birds and mammals, the members of which have the added advantage of homoiothermy. Birds and mammals traditionally form the zoogeographer's stock-in-trade; but a proper assessment of the status of the southern temperate region of Africa is only possible if these groups are seen in a balanced perspective.

HIGHER EDUCATION IN THE UNITED STATES

Dr. J. B. CONANT has recently examined some of the ambiguities between school, college and university in the United States and compared the American approach to the university with that of certain European countries (*Proc. Amer. Phil. Soc.*, 104, No. 6; December 15, 1960).

Conant believes that the comparison between the large numbers of American youth attending a college or university and the small numbers enrolled in European universities is misleading. A European university is essentially a collection of professional schools. If one compares the percentage of an age-group attending universities in a European nation and those attending American postgraduate institutions, the difference is not very striking.

The road to the university in Europe does not pass through the equivalent of an American college. Instead, there are essentially pre-university schools for those who aim at university education. They offer a stiff academic course of eight or nine years in length centred on either: (*a*) Latin and Greek, or (*b*) Latin and a modern language (or two) and (*c*) modern languages, science and mathematics. In each of the German States, and in each of the Swiss cantons, there are three types of pre-university schools, each preparing students to pass examinations for a State certificate which, in turn, provides admission to a university anywhere in the country.

The American liberal arts college is in the nature of an accident. During the nineteenth century the programmes which were offered for the first degree in arts or science, or in letters, were expanded to include a number of practical subjects. This fact makes it difficult to explain to a European what is meant by an American college. Within a university, too, there is a great variety of four-year programmes of study which may be entered directly by high-school graduates.

An American college is possibly intermediate between a high school and a 'university' in the European sense of the word. For the most part, those who become lawyers now study three or four years in an undergraduate department of a university, or in a four-year liberal arts college before they enrol at a law school; the same is true of medical students. On the other hand, engineering schools never became postgraduate schools. As a consequence, high-school graduates enter directly on their professional training if they want to become engineers. With so many complications in mind, it is hard to define without ambiguity the relation of a college to the education of members of the learned professions.

There is another ambiguity inherent in the American pattern of higher education. The standards of admission to the American colleges and universities are so varied as to, make it impossible to describe them accurately.

Standards for the first degree are almost as diverse as the standards of admission; the mere holding of a bachelor's degree has almost no significance. Yet no one would publish a rank list of institutions or even be willing to be quoted publicly to the effect that a straight '*A*' record in one college has about the same meaning as a '*C*' record in another. In the United States, there is a hierarchy of institutions granting the first degree and a complete conspiracy of silence as to the existence of such a hierarchy.

On entrance tests, Conant recommends that leading professional schools of law and medicine and graduate schools of arts and sciences might require their candidates to pass a set of examinations which would demonstrate a mastery of academic subjects somewhat comparable to that required for entrance into a European university. The requirements might be as follows: a good reading, writing and speaking knowledge of at least one foreign language; a knowledge of mathematics as far as the calculus; a knowledge of physics, chemistry and biology at the freshman college-level; the ability to write a competent essay; a knowledge of American history and political constitutions at a sophisticated level; and a knowledge of English and American literature at a corresponding level.

The variety of colleges prevents any uniform set of standards for admission. Therefore, the colleges could not, even if they desired, greatly influence the high-school curricula. But the relatively homogeneous nature of the graduate and professional schools makes the formulation of standards possible. The effect of this formulation would influence both colleges and high schools.

CIRRHOSIS OF THE LIVER IN FRANCE

AN investigation was recently undertaken by the nutrition department of the Institut national d'Hygiene, Paris, into the role of alcohol in the ætiology of cirrhosis of the liver in France (*W.H.O. Chronicle*, 14, December 1960).

Cirrhosis of the liver is relatively more common in France than in the rest of Europe; the death-rate in 1956 was the highest in Western Europe (32·5 per 100,000 inhabitants, as against 2·6 in England and Wales and 13·6 in the Federal Republic of Germany). For many years the medical profession in France has attributed the high incidence of the disease to the excessive consumption of alcohol, and statistics from hospitals agree that 80–85 per cent of cirrhoses are alcoholic in origin. But the medical profession has been accused of prejudice, and wine merchants have put forward the argument that in a population of whom 80 per cent are drinkers, it could be maintained that practically all illnesses are alcoholic in origin.

The survey was designed to answer five questions: did persons believed to have cirrhosis of alcoholic origin drink more before their illness than random controls of the same age, same sex and same social environment without cirrhosis; were they less well nourished (that is, is cirrhosis due to alcohol or to an associated nutritional deficiency); is the reduced food intake so often seen when cirrhosis becomes decompensated a cause or a consequence of the decompensation; can the amount of alcohol that causes cirrhosis be determined; and what part does wine play in the alcoholism of cirrhotics?

The survey was carried out in hospitals in Paris, Marseilles, and Nantes, all patients with alcoholic cirrhosis being questioned and a non-cirrhotic control being chosen at random in the same department for each patient questioned. The physical activity at work and outside work, the height and the usual weight before cirrhosis began were recorded, and a detailed food questionnaire was devised to establish the daily food intake before and after the onset of the disease, as well as the quantity of alcohol absorbed daily. In addition, questions were asked to reveal the social background about the patients' family and parents, income, living conditions and standard of living.

In all, 116 cirrhotics and 116 controls were compared. They did not differ significantly in age, physical activity, weight, or calorie or protein intake; but the alcohol intake of the cirrhotics was found to be approximately 2·5 times greater than that of the non-cirrhotics. Before they fell ill, the cirrhotics has been just as well nourished as the others; consequently, it was concluded that cirrhosis cannot be attributed to dietary deficiencies.

Only one out of the 116 patients with cirrhosis said that he had consumed less than 80 gm. of alcohol (that is, less than 1 litre of wine at 10°) daily. From this it may be inferred that alcoholic cirrhosis appears only when consumption of alcohol is greater than 1 litre a day. But 50 out of the 116 controls consumed 80–160 gm. of alcohol a day (1–2 litres of wine), and it was only in the category from 160 gm. of alcohol (2 litres of wine) up that controls tended to decrease in number (7 out of 116), while more than half the cirrhotics (64 out of 116) came within this range.

It seems reasonable to infer that cirrhosis is likeliest when the intake is between 2 and 2·5 litres of wine a day (172–212 gm. of alcohol). Cirrhosis can occur when it is 1 litre or more, but when it exceeds 2 litres the probability of its occurrence is much increased.

Is decreased food intake a decompensating factor in cirrhosis? Apparently not to any marked degree: in 88 cases out of the 116 it failed to cause decompensation; thus even at this late state the nutritional deficiency is only associated, not causal.

Finally, the survey established that wine represented 80–90 per cent of the alcohol ingested.

ELECTROLYTIC JUNCTION WITH AMPLIFYING PROPERTIES

By B. LOVREČEK and B. KUNST

Institute of Physical Chemistry, Technical Department, University of Zagreb

IN previous papers[1,2] it has been shown that the rectification of alternating electric current at a junction of two electrolytes is possible. This is analogous to the same effect at a junction of n- and p-type semiconductors. It is to be expected that other effects in semiconductors, for example, the amplification of electric current, have analogies in electrolytes. The purpose of this article is to report that this has been achieved.

The electric circuit is similar to that used with Ovitron amplifiers[3]. The essential difference between the Ovitron and the device reported in this article is that the active parts of Ovitron amplifiers are metal-metal oxide electrodes, and here electrolyte-electrolyte junctions.

The device (Fig. 1) consists of two rectifying elements of the type described earlier[1], turned face to face in such a way that, in the ideal case, alternating current in the main circuit could not pass through. Each of the rectifying elements consists of two ion-exchange membranes : cation in H^+ form and anion in OH^- form ('Zerolit permaplex' *C*-20 and *A*-20, respectively, United Water Softeners, Ltd., London). A thin, perforated polyvinylchloride sheet (0·025 mm. thick) is placed between the membranes to reduce the active surface of the rectifier. Ion-exchange membranes are always wet, due to sheets of filter paper soaked in pure water, and attached to the membranes. The whole device is held together with three pieces of graphite, which also serve as electrical connexions.

Electric impulses (direct or half-wave rectified current) in the second, 'impulse' circuit pass through rectifying elements in forward direction. A full-wave rectifying tube, used as double diode, and a high resistance in that circuit prevents the flow of alternating current from the main circuit. The impulses from the impulse circuit cause the rectifying elements to become 'conductive', and the amplification of the current is observed as the result. The current in both circuits is measured on milliammeters (I_1, I_2), and the current in the main circuit is also followed on a cathode ray oscilloscope screen. Alternating current (50 cycles per sec.) is applied in the main circuit. The pulsating voltage in the impulse circuit is obtained from alternating current of the same frequency and phase as that in the main circuit by passing through the diode. If the current passing through the main circuit has not exactly the sine form, the milliammeter does not show the right value. Therefore the curves on the cathode ray oscilloscope screen are photographed and the exact values of the current obtained by integration.

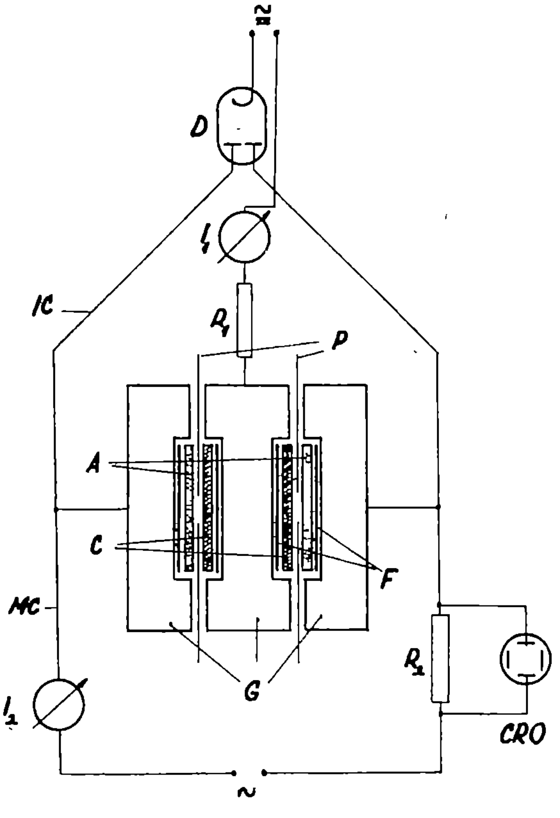

Fig. 1. Schematic presentation of device: *IC*, impulse circuit; *MC*, main circuit; *A*, anion exchange membranes; *C*, cation exchange membranes; *G*, graphite pieces; *P*, polyvinylchloride sheets; *F*, sheets of filter paper; R_1, R_2, resistances; I_1, I_2, milliammeters; *D*, double diode; *CRO*, cathode ray oscilloscope screen

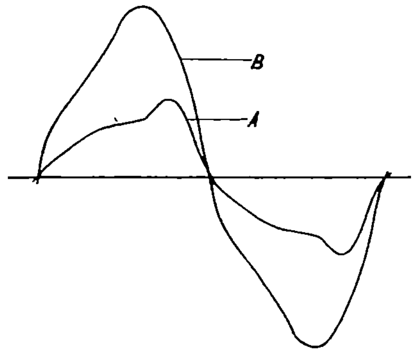

Fig. 2. Typical curve with direct current in impulse circuit: *A*, current in the main circuit before impulse is applied; *B*, current in the main circuit during the impulse

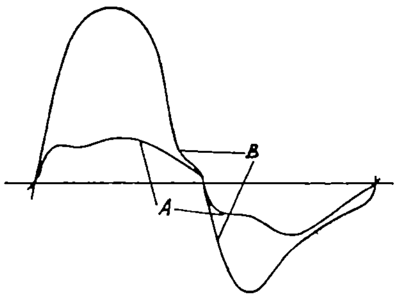

Fig. 3. Typical curve with rectified sinusoidal alternating current in impulse circuit: *A*, current in the main circuit before impulse is applied; *B*, current in the main circuit during the impulse

In each experiment, first the current in the main circuit is determined (it is different from zero, because of non-ideal rectification). Then, the impulse circuit is switched on, and immediately the current in the main circuit is determined again. The impulse circuit remains closed until the current in the main circuit stabilizes (1 min.). The stabilized current is determined, the impulse circuit cut off, and the current in the main circuit, in 'unconductive' state, is determined again.

The amplification is obtained by means of the equation :

$$\text{per cent amplification} = \frac{i_m - i_s}{i_s} \times 100$$

where i_m = the increase of current in the main circuit, and i_s = the current in the impulse circuit.

When the direct voltage in the impulse circuit is applied, the amplification, immediately after closing this circuit, is about 60 per cent and, after stabilization, about 100 per cent. In the case when pulsating voltage is applied, amplifications of 45 per cent and 80 per cent are obtained. Typical curves with direct and pulsating current are shown in Figs. 2 and 3.

Curves *A* in Figs. 2 and 3 represent non-ideally rectified alternating current. Both halves of the cycle are equally distorted, because the current passes through two rectifying elements, turned face to face (Fig. 1). The current increases symmetrically in both halves of the alternating-current cycle if direct current is applied in the impulse circuit over the full alternating current cycle (curve *B*, Fig. 2). If the impulse is a half-wave rectified sinusoidal alternating current of the same frequency and phase as that in the main circuit the situation is different (Fig. 3). The first half of the main circuit alternating-current cycle is that in which the impulse is applied, and an increase of the current is observed. But an increase is also observed in the second half of the cycle, where no impulse is given (curve *B*, Fig. 3). In such cases evidently the amplification has a certain time-lag. This 'frequency-response' of such systems is very interesting, and it is the object of further investigations.

In both cases (direct or alternating current impulse), the current in the main circuit not only increases but also the shape of the curve approaches the sinusoidal form. This is strong evidence that the amplification is a consequence of a diminished rectifying action, caused by an electrical impulse, which impels the ions toward the rectifying interfaces.

We wish to thank Dr. I. Hruška for helpful discussions of this work.

SOME FACTORS INFLUENCING THE FOOD-CHAIN TRANSPORT OF RADIOACTIVE MATERIALS INTO COW'S MILK

By D. MERTEN
Physikalisches Institut der Bundesforschungsanstalt fur Milchwirtschaft, Kiel
AND
O. SUSCHNY
Laboratory of the International Atomic Energy Agency, Vienna

VARIATIONS in the radioactive contents of milk have been observed and have been variously attributed to seasonal influences, changes in feeding practices, varying contamination-rates, etc.[1–4]. No detailed explanation of the fundamental principles underlying these variations has yet been presented. The following approach provides a method by which such variations can be explained.

The discussion is based on the fact that cows are fed on grass, hay, etc., which, prior to its consumption by the animal, has been exposed to radioactive contamination over a period of time. The general applicability of the proposed method will be shown in three model cases which illustrate three combinations of basic conditions :

I. (*a*) Constant feeding conditions throughout the year ; (*b*) contamination of the fodder with radioactive material at a constant rate. II. (*a*) Constant feeding conditions throughout the year ; (*b*) contamination with radioactive material at a varying rate. III. (*a*) Seasonal variations of feeding conditions ; (*b*) contamination with radioactive material at a constant rate.

Two assumptions are made in order to simplify the presentation : (*A*) Contamination of milk is assumed to be essentially proportional to the contamination of the diet of the cattle. (*B*) Contamination of the diet is assumed to be essentially proportional to the product of the rate of contamination by the time of exposure.

Other factors which influence to some degree the contamination of fodder and milk are not introduced in the discussion of the three model cases because they do not affect the basic considerations.

In the graphic presentation of the three model cases I, II and III (Figs. 1 and 2) twelve successive conditions *A*–*L* are shown for each of these model cases. In each sub-graph of this presentation the abscissa gives the time-scale while the ordinate

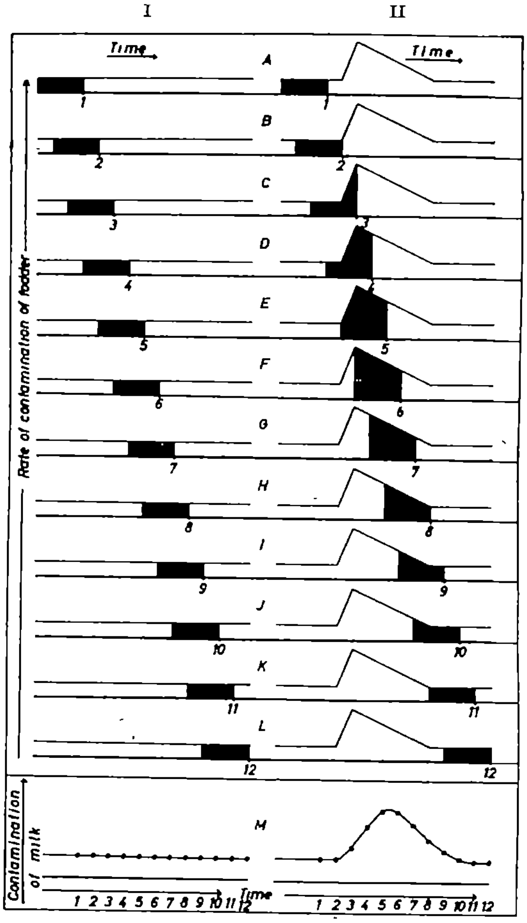

Fig. 1

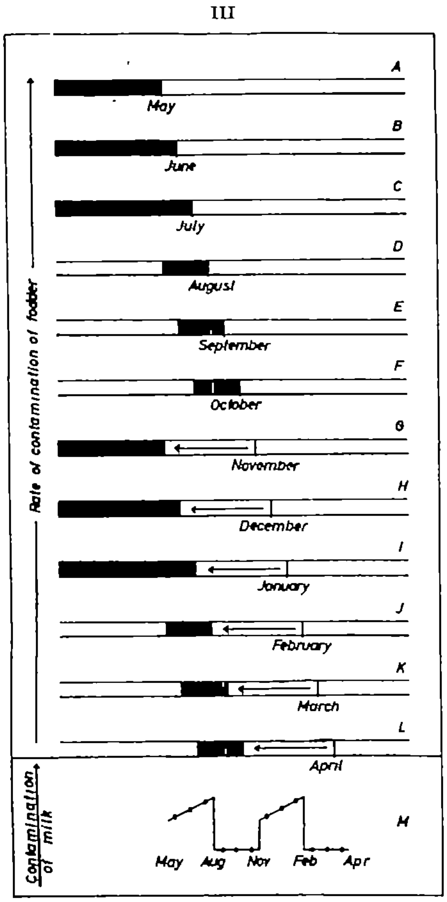

Fig. 2

indicates the rate of contamination. The total amount of radioactivity supplied with the grass to the cattle at times 1–12 is shown by the shaded areas in sub-graphs *A–L*. Sub-graphs *M* show the resulting contamination of the milk as a function of time.

The graphic presentation in model case I (constant feeding conditions, constant rate of contamination) shows clearly that the contamination of the milk remains constant, as shown in sub-graph (I) *M* of Fig. 1.

In model case II (constant feeding conditions, variable rate of contamination) the rate of contamination is assumed to rise gradually to a maximum at time 3, slowly returning to 'normal' at time 8. The cows feed on grass contaminated by amounts of radioactivity equal to the shaded areas of sub-graphs (II) *A–L*, respectively. At time 3 they consume grass which has for a considerable time been exposed to contamination at a low rate and for some time to contamination at a high rate. The total accumulated contamination of the grass ingested by the cattle at time 3 for that reason is somewhat higher than at times 1 or 2. Thus contamination of milk will increase until a maximum is reached between times 5 and 6. Later, milk contamination decreases again, and at time 11 it reaches its original value.

The result is demonstrated in sub-graph (II) *M* : the maximum rate of contamination at time 3 causes a maximum of milk contamination at times 5–6.

Model case III, shown in Fig. 2, illustrates a typical case approximating conditions in a country where the feeding conditions change with the seasons. The rate of contamination of the fodder is assumed to be constant.

Sub-graphs *A–L* illustrate the following pattern of feeding conditions : cows are kept in a barn until May. During this time they are fed on hay harvested during the previous year. In May they are led to the pasture (sub-graph *A*). The grass they feed on from May until July has not been cut since November of the previous year and has been contaminated at a constant rate (sub-graphs *A–C*). By August the cattle return to pastures which have already once been grazed in spring. They start eating grass grown since May and thus exposed to the constant rate of contamination for three months only. They feed on this pasture from August until October (sub-graphs *D–F*). After this time, they return to the barn and are again fed on hay harvested between May and July, as indicated by the arrows (sub-graphs *G–I*), and between August and October (sub-graphs *J–L*). respectively.

Sub-graph *M* of Fig. 2 shows the resulting contamination of the milk from cattle fed under these conditions. It shows that two distinct peak periods of radioactive contamination must exist during the year, even though the rate of contamination remains constant.

The above analysis has not taken into account the influence of variations in food composition. In practice, in many countries of the northern hemisphere, cows are fed on mixtures of hay and concentrates from November to April.[1] These concentrates, consisting of oil cake, etc., contain as a rule very little contamination. For this reason the November–January peak-level should be lower than the May–July peak-level, and the February–April values should be lower than the August–October values. Hay, on the other hand, is not always fed in the sequence in

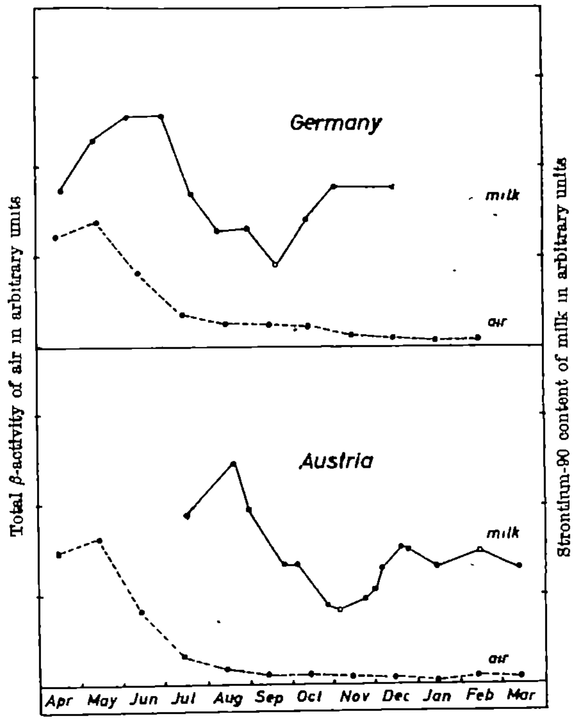

Fig. 3. Radioactivity of milk and air 1959/60

which it was harvested, and this will tend to level off differences between the values for the periods November–January and February–April. In addition, we have to consider the influence of varying deposition-rates superimposed on the seasonal variations of feeding conditions.

In order to demonstrate the applicability to actual conditions of the theoretical considerations discussed in the three model cases, Fig. 3 is presented. It shows the results of measurements of strontium-90 in milk from German and Austrian sources carried out in 1959 and 1960 at the Bundesforschungsanstalt für Milchwirtschaft, Kiel, and at the provisional laboratory of the International Atomic Energy Agency, respectively. These values are shown in relation to results of measurements of radioactivity in air[5,6].

In Germany and Austria conditions are comparable to those considered in model case III. The reasons for the delay between the appearance of a maximum of radioactivity in air and a corresponding maximum of contamination in milk have been discussed in model case II.

Similar results have been reported from sources in the United Kingdom, Canada and the United States[7-10].

DIQUAT AS AN ARBORICIDE

By J. S. GUNN and P. B. TATHAM

West African Institute for Oil Palm Research, Benin City, Nigeria

SODIUM arsenite has been widely employed as an arboricide and herbicide, but in various countries its use is being progressively restricted or prohibited. Investigations are being carried out at the West African Institute for Oil Palm Research with a variety of herbicides and other chemicals to find an alternative to sodium arsenite for poisoning old oil palms prior to, or concurrently with, replanting. So far diquat, a new desiccant and herbicide first described by Brian *et al.*[1], is the only one that has been found to be consistently effective and it is believed that this is the first record of its use as an aboricide.

The palms used in the trials were planted in 1939 and had attained a height of 25–30 ft. During the rainy season diquat was poured into a small, slightly downward sloping hole about 8 in. deep, punched 2–3 ft. from the ground in the trunk of the palm with a crowbar. The hole was then almost filled with water. Two separate trials were carried out, four palms being treated at each dosage-rate. Diquat was introduced at the following rates of active ingredient per palm:

First trial: 20 gm., 50 gm.
Second trial: 10 gm.; 20 gm.; 40 gm.; 60 gm; 10 gm., followed by a further 10 gm. after three weeks.

The effect at rates of 40 gm. and more was very rapid. Within two weeks of poisoning, all palms which had received these high rates had suffered almost complete desiccation of the older fronds and in some cases desiccation had proceeded as far as the central spear. At the 20-gm. rate the symptoms appeared more slowly, but followed the same course. It was evident that 10 gm. is too little to kill an adult palm and two applications of 10 gm. at three-week intervals were less effective than the single application of 20 gm.

After six weeks the fronds in most of the affected palms had collapsed basally and remained cloaking the stem; in other palms the fronds dried out in their normal position with some fracturing along their length. In all but one palm the spear remained erect but dried out. This is in contrast to the appearance of palms poisoned by sodium arsenite, where the spear usually falls out and the trunk collapses at any point along its length within two months of poisoning[2]. The collapse of the trunks of palms poisoned by diquat is, however, only a matter of time.

One palm receiving 50 gm. diquat was felled three weeks after poisoning. The expanded fronds were all dead; but the spear and one immature frond were still green. Internally the trunk appeared drier than normal with some pink discoloration of tissues around and below (but not above) the point of injection. A longitudinal section through the growing point showed no abnormal symptoms at that time. At the centre of the rachis of each dead frond, a pinkish brown discoloration was evident which was more advanced distally; it appeared to have started in the pinnæ and spread backwards. Transverse sections of some leaf bases showed slightly discoloured, water-soaked areas.

Another palm which had received 50 gm. diquat, was felled and examined after five and a half weeks; all the pinnæ were desiccated, but there were green areas in the spear and in an immature frond. A longitudinal section through the crown showed that the pinkish brown discoloration had spread to the leaf bases. The entire central portion of the rachis was coloured brown and there were roughly circular areas infected by a black rot. The rot appeared to be invading the spear in an irregular manner, some portions remaining green, others becoming desiccated and brown. The rot had penetrated to within a foot above the growing point, and the whole crown emitted a slightly putrid odour.

Three palms in the second trial were felled two months after poisoning. Symptoms in those which had received rates of 20 gm. diquat and more were similar, but the development of symptoms was more advanced at the higher rates. A soft, wet rot was observed in the trunk, affecting half the area near the point of injection. The tissues between the vascular bundles had completely broken down and this area was demarcated by a dark brown line. The tissue outside this area was obviously not normal, some tissue breakdown having occurred and the colour being a more yellowish pink than in a normal palm. The growing point was found to be completely destroyed by a wet, putrid rot. There was evidence of wide translocation of the poison; sectioning of the roots revealed brown to black discoloration of the vascular strands and a breakdown of cortical tissue.

At present this method of poisoning is expensive, but diquat has proved more effective than sodium arsenite, which, in West Africa, has given erratic results, except at much higher rates than those found necessary in Malaya[2]. The comparative safety with which diquat may be handled and used is an important point in its favour.

The purpose of this article is to direct attention to the arboricidal properties of diquat; the satisfactory results obtained with it for poisoning oil palms suggest that its use in this way may be of wider application. The samples used were kindly made available, as 'Reglone', by the manufacturers, Imperial Chemical Industries, Ltd.

'ACTIVE CENTRE' STUDIES IN TRYPSIN

By TERESA THERATTIL-ANTONY*, M. BIER and F. F. NORD

Laboratory of Organic Chemistry and Enzymology, Fordham University, New York

THE understanding of the mechanism of enzyme action presupposes a knowledge of structural elements of both substrate and the enzyme. This is relatively easy for substrates, which are usually of low molecular weight, but has not yet been achieved for any enzyme because of the complexity of the protein molecule. The essential structural requirements of the enzyme are referred to as its 'active centre'. They should be distinguished from those structural elements of the enzyme necessary for the preservation of its native configuration and not participating directly in the binding or activation of the substrate.

In the particular case of trypsin, its substrate requirements were believed to have been solved earlier[1]. Employing synthetic polypeptides, it was reported that trypsin will only catalyse the hydrolysis of bonds involving the carbonyl groups of the basic amino-acids arginine and lysine. This observation, though essential, did not contribute to the knowledge of the active centre of trypsin. Paradoxically, most of our information about the active site came from the discovery that trypsin and its close analogue chymotrypsin act on substrates bearing no apparent similarity with the above-mentioned ones. These are nitrophenyl acetate (NPA)[2] and di*iso*propylfluorophosphate (DFP)[3]. The latter reacts with trypsin and chymotrypsin in a mole-for-mole ratio to give stable inactive products, the *p*H curve of inactivation being similar to that of the enzymic activity. With NPA, chymotrypsin is inactivated, yielding a monoacetyl derivative. At lower *p*H values, for example, *p*H 5–6, the acetyl group is stable in aqueous solution and reactive towards hydroxylamine[4,5], while at *p*H 7–8 hydrolysis occurs, yielding acetate ions and reactivated enzyme. The group reactive towards NPA could also be readily acylated by various acid anhydrides and acid chlorides employed in an equimolar ratio. With trypsin, hydrolysis of NPA is observed, but no inactivation of the enzyme takes place.

The foregoing observations have implicated the seryl and the imidazolyl residues of trypsin as possible functional groups involved in enzyme action. Another approach to the problem of the active centre has been carried out with the aid of reagents specific for various functional groups in proteins. Acylation of amino-groups left the enzyme still active, while esterification of the carboxyl group gave only partially active protein. However, iodination of the phenolic groups and sulphation of the hydroxyl groups rendered the enzyme completely inactive.

This approach lacks the desired specificity, as all proteins possess essentially the same limited number of reactive groups as part of their structure. Accordingly, the key to their specificity is to be sought in the spatial distribution of these groups as conditioned by the general geometry of their molecule, the charge distribution and its fluctuation, and the possibility of resonance and chelation with the substrate. Hence, it is possible to influence the properties of an enzyme through modification of these factors by either blocking accessible reactive groups or introducing new groups into its molecular structure. In this Laboratory such a broader view of chemical modification was taken, since each derivative formed, even though it may still retain enzymic activity, has acquired a new set of properties which differentiate it from the parent enzyme, or any other of its derivatives. For example, the series of acyltrypsins, obtained through reaction of the native trypsin with seven anhydrides of mono- and di-carboxylic acids, differed in their proteolytic and esterolytic activities[6], Michaelis–Menten constants, *p*H optima and dissociation constants with their inhibitors, ovomucoid[7] and serum inhibitor[8]. All these parameters of enzyme action depend directly, one presumes, on the interaction between substrate and enzyme on the level of its active site. Strikingly enough, in some instances, far greater differences were observed in trypsin properties not related to the active site but to its general molecular dynamics. These are: stability towards acid, alkali and urea denaturation and self-digestion[9], ease of reversibility of heat denaturation[10], electrophoretic and ultracentrifugal properties and isoelectric points[7]. As the reaction under the conditions employed causes mainly acylation of the amino-groups, it is obvious that the reacted amino-groups are not indispensable for enzyme action. As they modify it, however, they could be located peripherically to the active centre. A varying area of tryptic active site would also account for the repeatedly observed different effects of chemical modification, when several substrates are used. Most striking is the insensitivity of the active site of trypsin to overall charge distribution on the protein, as the isoelectric point can be changed from 10·8 of the native enzyme to about *p*H 4 of succinyltrypsin, without greatly affecting its parameters of enzyme action.

---

* Permanent address. Department of Chemistry, University of Delhi.

Earlier work in this Laboratory with citraconyl and itaconyl trypsin has shown that their proteolytic, but not esterolytic, activity increased on incubation at various *p*H values. Obviously, a direct modification of the active site was involved. This prompted us to investigate the early phases of acylation and its effects on proteolytic activity, which were neglected in most previous work. It was observed that the proteolytic activity of trypsin decreases radically, sometimes even completely, within 3–8 min. on addition of various anhydrides, a slow reactivation taking place on further incubation of the acetylating mixture[11]. Both, inactivation and reactivation, are strongly *p*H dependent. Immediate reactivation can be obtained with hydroxylamine.

Acetylation of Trypsin with Acetic Anhydride

Acetylation in sodium acetate. In the first series of experiments the acetylation was carried out by a slight modification of the customary method[12], employing 0·5 *M* sodium acetate buffer rather than a half-saturated solution. The acetylation mixture was maintained at 0° C. and kept uniformly stirred by means of a magnetic stirrer. The proteolytic activity was determined on urea-denatured hæmoglobin at various times after the addition of anhydride. The *p*H of the hæmoglobin substrate was adjusted to give a final *p*H of 7·8–8·1 on the addition of the acetylating mixture. The concentration of the split products was determined from the absorption at 280 mμ using a Zeiss *PMQ*II spectrophotometer for the activity measurements.

Results presented in Fig. 1 show that there is a slight loss of activity even on addition of one equivalent of acetic anhydride per mole of trypsin.

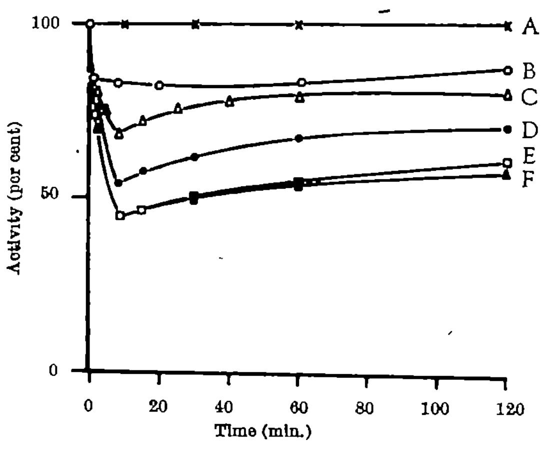

Fig. 1 Acetylation of trypsin with various amounts of acetic anhydride. 5 mgm. of trypsin in 10 ml. of 0·5 *M* sodium acetate was acetylated at 0° C. with: *A*, 80 equivalents acetic acid; *B*, 1 equivalent acetic anhydride; *C*, 4 equivalents; *D*, 20 equivalents; *E*, 40 equivalents, and *F*, 60 equivalents

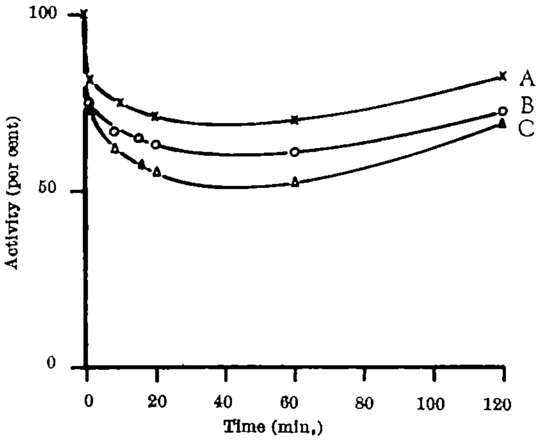

Fig. 2. Effect of buffer concentration. 5 mgm. of trypsin in 10 ml. of solution was acetylated with 40 equivalents of acetic anhydride containing: *A*, 20 mgm.; *B*, 100 mgm.; *C*, 200 mgm. sodium acetate

Maximum loss of activity occurs when 40 equivalents or more of anhydride are employed. There is a serious loss of activity within 1 min. of acetylation. At about 8–10 min. of acetylation, the activity reaches a minimum and begins thereafter to increase. Control experiments show that there is no change in activity on addition of 80 equivalents of glacial acetic acid to the enzyme solution, nor is there a change in activity if acetic anhydride is added to the substrate prior to the addition of the enzyme in amounts corresponding to that present in the enzyme sample used. Customarily, acetylation is performed in half-saturated sodium acetate at 0° C. employing 1·2 ml. of acetic anhydride per gram of trypsin. In Fig. 2 is shown the decrease in activity as the buffer concentration is increased during acetylation. The observed effect is probably due to the increasing alkalinity of more concentrated solutions.

The results of repeated additions of small amounts of anhydride are listed in Table 1. At the first few additions there is a decrease in activity followed by a slow increase. The effect is smaller, however, on second addition, and practically disappears on the third and the fourth. The acetylation of the enzyme during the first addition has an obvious protective effect. The substitution of calcium acetate for sodium acetate did not, however, change the general pattern of the reaction. Similarly, neither did the acetate salts of potassium, magnesium, manganese, barium, aluminium and lead, provided that the *p*H of the acetylating mixture was in the range of 5·5–6·0.

Acetylation at constant pH values. The change of the *p*H of the buffer had, however, far greater effects, if, for example, 0·5 *M* buffers of sodium and potassium carbonate, bicarbonate and borate were used. Under these conditions the proteolytic activity approached zero within 1–3 min. on addition of

Table 1. REPEATED ACETYLATION OF TRYPSIN WITH FOUR EQUIVALENTS OF ACETIC ANHYDRIDE

Time (min.)	Per cent activity			
	First addition	Second	Third	Fourth
0	100	74	76	77
8	77	71	71	76
20	74	73·5	72·5	76·5
30	76·5	76	76	77

anhydride, and, as before, a reactivation took place on incubation of the acetylating mixture[11]. To be able better to explore the dependence on *p*H of both inactivation and reactivation, an automatic titrator was employed in subsequent experiments. The enzyme was dissolved in distilled water and the titrator started at the same time that 65 equivalents of anhydride were added. The *p*H was maintained at the preset value throughout the experiment. The lack of excess buffers permits easier readjustment of *p*H during reactivation studies. In Table 2 is shown the extent of the maximum loss of activity at various preset *p*H values. It is evident that as the *p*H is lowered from 9 to 5 the extent of inactivation decreased from 100 per cent to about 40 per cent. Calcium ions do not have any protective action when acetylation is carried on under the above conditions. The maximum reactivation observed so far amounts to about 50–60 per cent of the native trypsin and to about 80–90 per cent of control samples of acetyltrypsin obtained after exhaustive dialysis and lyophilization. The discrepancy may be due to the fact that trypsin is in equilibrium between a denatured and native form, the latter yielding a fully active acyl derivative while the reversible denatured form becomes irreversibly denatured on acetylation[12].

Table 2. ACETYLATION AT DIFFERENT *p*H VALUES

*p*H	Activity (per cent)			
	0 hr.	8 min.	4 hr.	24 hr.
5	100	62·9	72·5	72·5
6	100	35·1	42·8	42·8
7	100	25·2	44·3	44·1
8	100	0	44·8	44·1
9	100	0	42·7	40·8

The spontaneous reactivation progresses slowly on incubation, but an almost instantaneous reactivation takes place on treatment with hydroxylamine. After 8 min. of acetylation 4 equivalents of hydroxylamine hyrochloride per equivalent of anhydride were added to the acetylating mixture. The hydroxylamine solution was first brought to the *p*H at which the activation was to be carried out and the *p*H of the caetylating mixture controlled by the automatic titrator. Reactivation was measured after further incubation of 8–10 min. at 0° C. The percentage of reactivation with hydroxylamine as a function of *p*H is illustrated in Fig. 3. Curve *A* shows the extent of activation obtained by spontaneous reactivation without hydroxylamine on incubation of the acetylating mixture at the indicated *p*H values for the same length of time. It can be seen that above *p*H 7 the spontaneous reactivation is not measurable within the incubation period of 8 min. On the contrary, with hydroxylamine (curve *B*) maximum reactivation occurs in the *p*H region of 8–9·5. (Chymotrypsin behaves similarly to trypsin, and its acetylation at *p*H 8 or above results in a reversible inactivation. Maximum reactivation with hydroxylamine takes place in the region of *p*H 7·5–8·0.) This dependence on *p*H of the reactivation is indicative of the presence of O-acetyl groups which react with hydroxylamine in this *p*H region[14]. The spontaneous acid hydrolysis confirms this suspicion. Under the same conditions aliphatic ester, such as ethyl acetate, did not react with hydroxylamine until above *p*H 11, while NPA reacts already at *p*H 6·5 and above. The group present in the enzyme has to have a reactivity intermediate to those of the above two compounds. The spontaneous hydrolysis is far more sensitive to acid than to alkali catalysis.

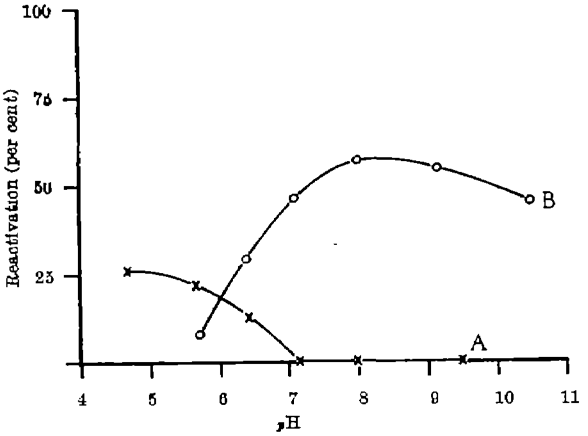

Fig. 3. Reactivation of acetyltrypsin at different *p*H values for an incubation period of 8 min. *A*, spontaneous; *B*, with hydroxylamine

It appeared possible that the imidazole moiety of histidine residues of trypsin can undergo acetylation and spontaneous deacetylation. It is known that acetyl imidazole has a high absorption in the ultraviolet region of 245–260 mμ[15]. Trypsin has 3 moles of histidine per mole of enzyme, and if these groups are undergoing acetylation and hydrolysis, then there should have been a marked increase and a slow decrease in the absorption spectrum at 245 mμ. In Fig. 4 it can be seen that the effect of addition of acetic anhydride to a sample of trypsin (curve *B*) resembles the course of hydrolysis of the acetic anhydride in the same buffer 0·4 *M* borate (curve *A*). The curves were corrected for the absorption of the protein itself. At the same time curve *D* shows an

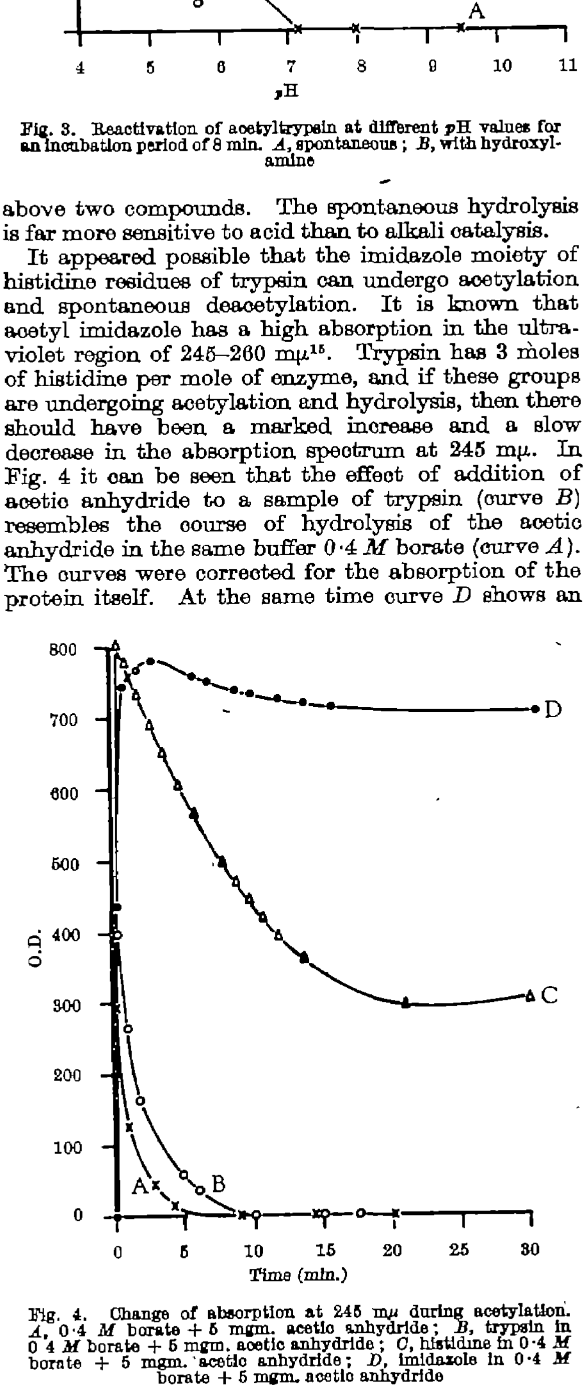

Fig. 4. Change of absorption at 245 mμ during acetylation. *A*, 0·4 *M* borate + 5 mgm. acetic anhydride; *B*, trypsin in 0·4 *M* borate + 5 mgm. acetic anhydride; *C*, histidine in 0·4 *M* borate + 5 mgm. acetic anhydride; *D*, imidazole in 0·4 *M* borate + 5 mgm. acetic anhydride

increase in absorbance from zero to 0·795 on the addition of the same amount of acetic anhydride to a sample of imidazole in a concentration corresponding to that of histidine in the trypsin sample. Curve *C* indicates the change in absorption of histidine under the same conditions; both these curves are quite different from those obtained with trypsin. It appears, therefore, very unlikely that an imidazole group is involved in the acetylation causing the inactivation of the enzyme, though a role of the group in deacetylation[16] cannot be excluded.

Discussion

Tracer experiments show that $DI^{32}P$ is attached to the hydroxyl group of a serine residue in the reaction causing inactivation of either trypsin or chymotrypsin[17,18]. Kinetic considerations led[19] to the postulation that the same group is acetylated also in the reaction of chymotrypsin and NPA. The resulting monoacetyl chymotrypsin can be isolated[20] and is remarkably stable in acid media, while rapidly hydrolysing between *p*H 7 and 8 (refs. 4 and 5). A variety of acylchymotrypsins was reported to be obtainable by reaction of the enzyme with stoichiometric amounts of acid anhydrides or acid chlorides[4]. All these derivatives are also stable in acid media and hydrolyse in neutral to slightly alkaline media. The dependence of hydrolysis on *p*H (as well as of acetylation of NPA) seems to involve catalysis by a neighbouring imidazole group. Direct spectrophotometric evidence for the intermediary formation of an N-acetyl imidazolyl derivative during the process of deacetylation was presented[16]. Detailed mechanisms for the reaction between the enzyme and NPA were postulated by several authors[19,21,22]. The same mechanism was extended also to the action of chymotrypsin on its normal peptidic substrates, though the evidence for it is largely indirect. For example, the *p*H dependence of hydrolysis of acetyl L-phenylalanine ethyl ester also implicates catalysis by an imidazole group[23]. This mechanism considers proteolytic enzymes as having a transacylating function, with water as the ultimate acyl group acceptor. It is most unfortunate that there is as yet no direct evidence for the actual formation of the acylated intermediates during peptidic hydrolysis.

In its reaction with NPA, trypsin behaves essentially similarly to chymotrypsin[4]. Exact comparison of the kinetic parameters and the *pK* values of the catalytic groups were first presented by Stewart and Ouellet[24]. A stable, inactive monoacetyl trypsin could, however, not be obtained by the authors following the technique used for chymotrypsin. Nevertheless, the rate of hydrolysis of the acetyltrypsin formed increases with *p*H at around neutrality, as shown by stopped-flow technique[24], and was easily confirmed by us.

In striking contrast with the foregoing results are the present results with acetic anhydride. The inactive acetyltrypsin obtained is unstable in acid media, but quite stable in neutral to slightly basic buffers. Similar data were obtained for a variety of other anhydrides[11]. The instability in acid media explains why no inactivation of trypsin could be observed, following the procedure[4] for the reaction of chymotrypsin with acetic anhydride (*p*H 5).

The acetylated group is presumably part of the active centre and is either an aliphatic or an aromatic hydroxyl group. The latter assumption is supported by its reactivity with hydroxylamine, which is intermediate to that of ethyl acetate and those of NPA or phenylacetate. Other groups seem excluded, as Uraki *et al.*[25] have shown that N-acetyl groups are resistant to hydrolysis even under stringent conditions, while the spectrophotometric data presented here preclude the acetylation of imidazole. The difference in *p*H dependence of spontaneous hydrolysis of the acetyltrypsin formed with NPA or with acetic anhydride would imply that two different hydroxyl groups are acetylated and are present in the active site of trypsin. The stability in alkaline media would apparently preclude the possibility that this latter acetyltrypsin is an intermediary in the course of normal enzyme action. An alternative possibility is that the difference in behaviour is due to the simultaneous acetylation of other groups as well, aside from the critical hydroxyl group, by the action of acetic anhydride, but not by the action of NPA. The group acetylated could be a primary amino-group, catalytically active in the deacetylation (and presumably also acetylation) of acetyltrypsin formed by the reaction of trypsin with NPA. This would be in agreement with the results of Stewart and Ouellet[24], who have shown that the hydrolysis of NPA can be catalysed by a combination of a free amino-group and an aliphatic hydroxyl group, namely, lysine methyl ester and *iso*propyl alcohol. The acetylation of the amino-group by the acetic anhydride would eliminate its catalytic role, accounting for the comparative stability of the inactive acetyltrypsin in neutral to alkaline media, while the hydrolysis in acid media may be due to simple acid catalysis. This would explain the difference in the behaviour from chymotrypsin, where an imidazole group has the same catalytic function.

This work was carried out under the auspices of the U.S. Atomic Energy Commission, the National Science Foundation and the U.S. Public Health Service.

MECHANISM OF COLLAGEN SYNTHESIS

By G. B. GERBER and K. I. ALTMAN

Division of Experimental Radiology, University of Rochester School of Medicine, New York

EXPERIMENTAL evidence[1-3] indicates that the mechanism underlying the biosynthesis of fibrous proteins, such as collagen or silk fibroin, differs from that operating in the case of globular proteins[4-7]. In this article a mechanism is proposed for the biosynthesis of collagen which could account for the experimental data available at present. This mechanism is based on the notion that collagen is synthesized by an enlargement of the pre-existing collagen fibre by means of the addition of amino-acids or peptide residues and would be analogous to that proposed for hepatic glycogen[8]. The proposed synthetic process is unlike that visualized for globular proteins, which are thought to be synthesized by one continuous process[4-7]. The *a priori* assumption seems reasonable that a long fibrous molecule which is considerably longer than the ribonucleic acid templates[9-11] is probably not synthesized in a single operation but rather by a step-wise addition of simple building blocks. The latter view is supported by direct evidence since it has been observed in this laboratory that the distribution of an isotope among identical amino-acid residues is non-uniform[1,2] after the injection of amino-acids labelled with carbon-14. A similar non-uniform labelling pattern has been found in the case of silk fibroin[12]. It is therefore postulated that discrete regions near the termini of the collagen molecule participate actively in the metabolism of this protein whereas regions distant from these termini are metabolically inert.

By varying the ionic strength or *p*H of the medium, fractions of collagen can be prepared differing from native collagen with respect to their isotope concentration and rate of metabolic replacement[13-18]. Although these fractions have generally been assumed to represent distinct molecular entities within the collagen group, a more plausible, alternative view would be that these fractions originate from the same molecular species of native collagen by a process of intramolecular cleavage. The following evidence may be adduced for the common origin of these fractions: (*a*) all collagen fractions derived from the same organs have almost identical amino-acid composition[19]; (*b*) when collagen is solubilized, the resulting fractions have similar molecular weights[2]; and (*c*) on sub-fractionation of native collagen, C- and N-terminal amino-acids become discernible in the resulting products[21-23].

The latter observation suggests that intramolecular cleavage occurs during the fractionation procedure. Certain peptide bonds, particularly those involving aspartyl residues[24], are probably ruptured preferentially. Specifically, it is postulated that peptides situated near the termini of a polypeptide chain of native collagen become detached under mild experimental conditions and give rise to neutral-salt-soluble collagen. Only when native collagen is treated more vigorously will amino-acid sequences located at a greater distance from the termini of the fibre become severed to form citrate-soluble collagen plus a residual core of insoluble collagen.

It follows from the preceding considerations that differences in the metabolic turnover of various fractions of collagen should be determined by differences in the distance of the point of intramolecular cleavage from the metabolically active terminus of the fibre. Such a view would offer a reasonable explanation for the higher level of isotope incorporation and the more rapid replacement of the fraction of neutral-salt-soluble collagen as compared with other fractions, such as insoluble collagen, since the former fraction is thought to have originated from peptide sequences vicinal to the termini of the fibre, whereas the latter fraction represents the metabolically inert core of the molecule.

In view of such apparent differences in the metabolism of various collagen fractions, speculation as to size and metabolic behaviour of the fundamental repeating unit of collagen seems pertinent. On the basis of the amino-acid composition and the nature of the peptides isolated by various investigators from partial hydrolysates of collagen, it seems unlikely that molecular enlargement takes place by means of the addition of single amino-acid residues to the termini of the fibre in a random fashion. It appears more probable that a polypeptide, pre-formed on a template, is added to the collagen fibre, thereby enlarging the molecule. The size of such a polypeptide building block can be delimited. The smallest possible size can be computed from the amino-acid composition whereas the largest possible size can be estimated on the basis of metabolic data pertaining to the incorporation of amino-acids labelled with carbon-14 (refs. 1 and 2).

The residues of glycine, proline, hydroxyproline, alanine, arginine, and glutamic acid recur with unusual frequency in the peptide chains of collagen and constitute 73 moles per cent of all amino-acid residues of this protein. Aspartyl, seryl and lysyl plus hydroxylysyl residues occur in concentration of 3–6 moles per cent, whereas valyl, *iso*leucyl, phenylalanyl, methionyl and threonyl residues occur in concentrations of 1–3 moles per cent. Histidyl and tyrosyl residues occur least frequently, namely, in concentrations of 0·7–0·9 mole per cent[25]. When computed on the basis of the amino-acid occurring least frequently, the smallest building block should contain about 140 residues and should have a molecular weight of about 12,000. Alternatively, it is conceivable that under the following two conditions the amino-acid residues recurring least frequently do not determine molecular size: (*a*) residues having a low frequency of recurrence appear only as constituents of branching chains which are formed later than the peptide chain, or (*b*) these residues form the link between two building blocks. Although the recent isolation of the tripeptide involving the ε-amino group of lysine[26] suggests the existence of such side chains, condition (*a*) appears unlikely since both amino-acid residues would have to occur in side-chains. If condition (*b*) were to prevail and the building blocks had polar and non-polar termini, these building blocks could be linked through histidyl or tyrosyl residues in two ways: (*a*) in a complementary way, that is, non-polar.polar–polar.non-polar, or (*b*) in an alternating fashion, that is, polar.non-polar–polar.non-polar. The complementary arrangement would have the advantage of accommodating readily both histidyl and tyrosyl residues so that these residues might serve in the capacity of bidentate links at the polar and non-polar termini, respectively. If these assumptions are valid, the lower limit for the size of the building block would be approximately 70 amino-acid residues and the minimal molecular weight about 6,000. Such a view is compatible with data on the composition of several polypeptides containing 20–80 amino-acid residues isolated by Grassmann *et al.*[27] as well as with the findings of Schroeder *et al.*[28], Heyns *et al.*[29] and Kroner *et al.*[30].

The upper limit for the size of the building block can be set only in terms of the ratio of the size of the building block to that of the collagen molecule. Since identical amino-acid residues in the collagen molecule are labelled non-uniformly, a ratio of about 1 : 3 for the highest to the lowest specific activity of such amino-acid residues may be considered a measure of the relative size of the fundamental building block.

The ratio of the size of the building block to that of the collagen molecule can also be computed from the ratio of the specific activities or of the turnover times of urinary 'free' and 'bound' hydroxyproline[3]. The former has a turnover time of about 0·5 day and the latter a turnover time of 15 days. The specific activity extrapolated to time zero after injection is about 50 times higher than that of bound hydroxyproline[3]. If one postulates that 'free' hydroxyproline is derived from the building blocks and 'bound' hydroxyproline from native collagen, the size of the building block may be estimated at 1/20 of the size of native collagen and would have a molecular weight of less than 3×10^5 as compared with an average molecular weight of 5×10^6 assumed for native collagen. The high specific activity in urinary 'free' hydroxyproline may also be a consequence of the unique process by which proline is hydroxylated when this amino-acid is part of a precollagenous peptide or related substances. One may postulate that the hydroxylation of proline occurs only at specific sites of the template at a time when constituents of the peptide chain are still incompletely assembled. Hydroxyproline may be assumed to have a low affinity for the template which facilitates the synthesis of the building blocks since hydroxyproline is known not to be incorporated into the nascent peptide chain of collagen and can arise only from bound proline[31–33]. Consequently, it is possible that certain hydroxyproline residues are eliminated from the template and constitute in part the source of 'free' hydroxyproline.

It is of interest to point out that an inverse relationship appears to exist in various collagen fractions between metabolic activity and carbohydrate content[19–24]. This fact may account for the differences between collagen fractions with regard to their respective solubility characteristics[25]. In spite of the low carbohydrate content of 1 per cent or less[36], the polysaccharide material may be of considerable physiological importance. One may speculate that the metabolically active terminal sites of collagen are capable of reacting with either polysaccharides or the peptide building blocks. The reaction with polysaccharides may be considered irreversible in nature and to proceed at an appreciably slower rate than the reaction with a building block, thus preventing further additions of building blocks at the sites involved. On the other hand, the reaction with building blocks is reversible and leads to enlargement or to branching of the collagen molecule. The simultaneous operation of these two reactions at the metabolically active sites of collagen would tend to restrict the process of branching and would, furthermore, provide a means of controlling the length of the peptide chain of collagen. Such a concept might be applied fruitfully to the study of metabolic inertness in relation to the process of ageing. In conclusion, it may be stated that the mechanism proposed here for the biosynthesis of collagen, although not entirely proved, suggests new avenues of approach to the study of connective tissue proteins.

COMPARATIVE EFFECTS OF LIVER AND TUMOUR RIBONUCLEIC ACIDS ON THE NORMAL LIVER AND THE NOVIKOFF HEPATOMA CELLS OF THE RAT

By Dr. S. DeCARVALHO and Dr. H. J. RAND
Rand Development Corporation, Cleveland, Ohio

THE Novikoff hepatoma of the rat seemed to be an appropriate model to test some of the hypotheses derived from experiments with human tumour ribonucleic acid (RNA)[1-6]. It is easy to transplant, and it offers the opportunity to compare experiments with the normal counterpart organ, the liver.

RNA from normal liver and spleen and kidney from Novikoff tumour of adult (250-gm.) female Sprague–Dawley–Holtzman rats was extracted by both phenol and fluorocarbon methods[2-4,6]. 50 gm. of normal or hepatoma tissue were thrown on dry ice and extracted immediately or preserved at −20° C. for a few days. The RNA preparation was always used on the same day of preparation (less than 2 hr. at 2° C.). The ultra-violet spectra of liver RNA and hepatoma RNA show the expected difference due to the reported richness of the latter in guanine[7] (Fig. 1). The hyperchromatic effect of both RNAse and temperature indicated near-native, undenatured state.

The Novikoff tumour on the fifth day of transplantation was collected and broken in an L. Blessig manual homogenizer in phosphate-buffered saline (5 gm. of tissue in 25 ml. of salt solution). The homogenate was filtered through two layers of gauze and the cells washed four times in the RNA solvent (0·06 *M* disodium versenate, 0·06 *M* phosphate buffer *p*H 7·0, 0·12 *M* sodium chloride).

The cells are counted and then re-suspended in the RNA solution at a ratio of 2,500 μgm. RNA/10^6 cells. The suspension is left in a large bottle lying on the side to prevent cell accumulation, at 2° C. for 15 hr.

It is known that when 90 mgm. of tumour tissue are injected intraperitoneally 92 per cent of the animals have 5–8 gm. omental tumours in 5–8 days[8]. Our routine passages confirmed these data.

In one experiment 40 animals received hepatoma cells four times washed with buffered versenate–saline, and left for 15 hr. at 2° C. (group 1). Another 40 animals received hepatoma cells incubated with normal rat spleen RNA (group 2), 40 hepatoma cells incubated with kidney RNA (group 3), 40 with hepatoma cells incubated with normal rat liver RNA (group 4) and another 40 with hepatoma cells incubated with hepatoma RNA (group 5). Table 1 summarizes the results of this experiment.

Tumours in groups 4 and 5 were different from routine tumours, such as in groups 1, 2 and 3. All were considered to be modified tumours; the modifications in group 4, however, were in opposite directions from group 5.

Tumours in group 4, derived from hepatoma cells treated by normal rat liver RNA, were small (2 mm. in size) slightly hæmorrhagic nodules scattered in the mesentery, and never formed a solid omental tumour. Histologically, they showed a more orderly cordonal organization with the tendency to radiate around a vein (Fig. 3). The nucleo-cytoplasmic and nucleolo-nuclear ratios were not as markedly increased as in the routine tumour, and the cells contained glycogen in a polarized distribution, resembling normal liver. The ascitic fluid was bloody, but also contained bile elements. Mitoses were infrequent. The morphochemical characteristics, the slow growth, the low percentage of takes and the

Table 1. Effects of Different RNA Preparations on Novikoff Tumour in Intraperitoneal Grafting

Group	RNA source	Percentage of tumours	Mean time of death (days)	Percentage of regressions
1	—	95	6	0
2	Rat spleen	94	6	0
3	Rat kidney	95	6	0
4	Rat liver	15*	12	85
5	Hepatoma	100	6	5

* Thirty-four animals still alive without tumours 95 days after inoculation. These animals were resistant to further tumour transplantations.

practical lack of lethality indicate a certain degree of re-differentiation of the original wild malignant tumour cells by the normal RNA preparation. That this action is specific to liver RNA is indicated by the fact that rat spleen and rat kidney RNA both failed to modify the tumour. These tumours were passed intraperitoneally in the usual way and did not produce the usual picture of the large malignant hæmorrhagic omental tumour in six days.

In Niu's experiments[9] Ehrlich ascites tumour cells of the mouse produced serum albumin and lost anaplastic features after treatment with liver RNA (from a mouse and a calf). It would be of interest to know whether or not they had regained malignant virulence on re-transplantation.

Since calf liver RNA in Niu's experiments was able to perform a liver-oriented differentiation (serum albumin secretion) by tumour cells, we decided to test the influence of heterologous liver RNA (rabbit) on the rat hepatoma. The following experiment was performed: eighteen rats were inoculated intraperitoneally with hepatoma cells treated by rabbit liver RNA (group 1). Six rats were inoculated with hepatoma cells treated by rabbit spleen RNA (group 2). Six rats were inoculated with hepatoma cells from the same batch used in group 1, washed in buffered saline and left for 15 hr. at 2° C.

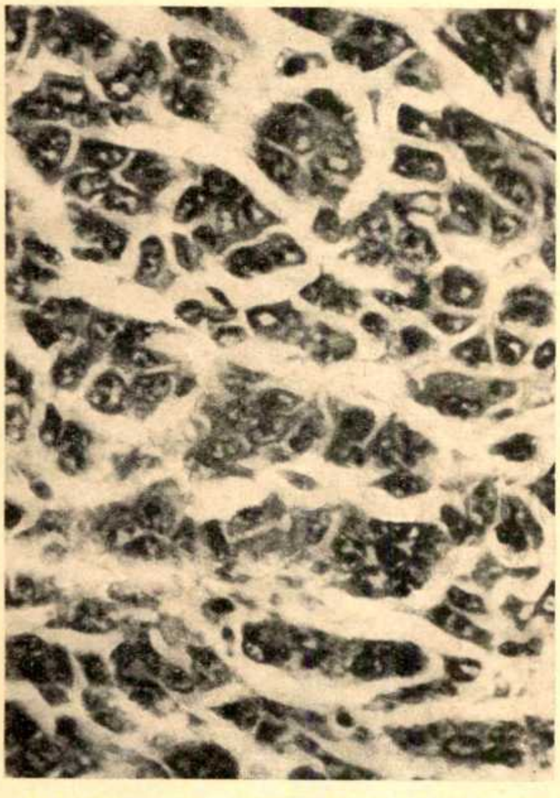

Fig. 2. Omental tumour, Novikoff hepatoma. (Histoid pattern × 275)

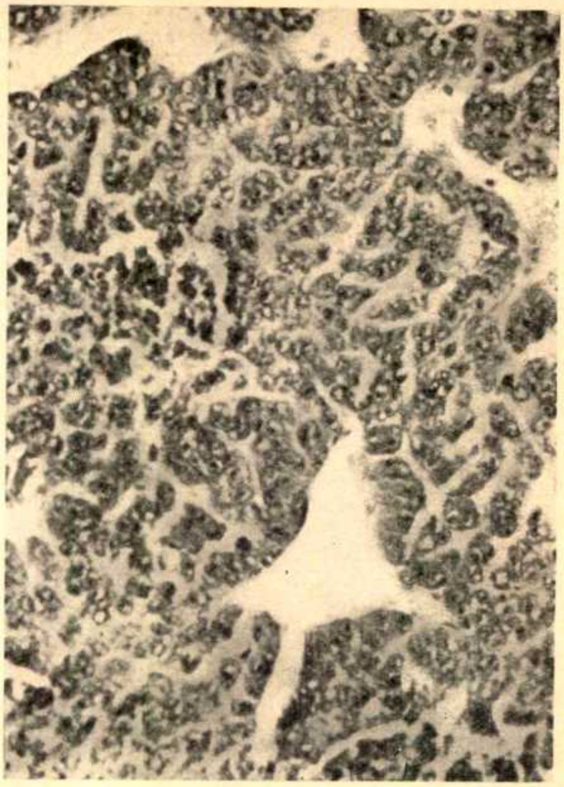

Fig. 3. Mesenteric nodule from transplantation of hepatoma cells previously treated by RNA from normal rat or rabbit liver. (Organoid pattern × 175)

An important determinant in the outcome of these experiments of tumour modification by normal RNA is the proportion of number of cells per mole of RNA. Any cell that will not incorporate enough or no RNA at all could be responsible for the restoration of the wild tumour. The exact conditions were not established in these experiments. An excess of RNA was always used to circumvent these pitfalls.

The following were the results on the sixth day after the transplantations:

Group 1. No large tumours visible. No anæmia or signs of hæmorrhage; less activity. Two animals were sampled. One had a few nodules of 1–2 mm. size in the omentum which on histological examination proved to be similar to the modified organoid type of tumours obtained with normal rat liver RNA.

Group 2. All animals had large tumours anæmic and weak; two had died on the fifth day.

Group 3. Three animals died on the sixth day with large omental tumours; the three remaining all had large tumours.

This experiment and Niu's seem to indicate that RNA from the different organs has morphogenetic-differentiating and enzyme-forming capacities that transcend species barriers and are common to homonymous organs of different species. This phenomenon is parallel to the similarity of endocrine secretions in heterologous systems and may be a fortunate event since it may allow use of specific

Table 2. EFFECTS OF DIFFERENT RNA PREPARATIONS ON NORMAL RAT LIVER CELLS

Group	Source of RNA	Percentage of tumours	Mean time of appearance (days)	Percentage of regression
1	—	0	—	
2	Liver	0*	—	
3	Hepatoma	20	15	5

* Small fibrotic nodules were sometimes found on the surface of the liver.

Table 3. EFFECT OF HEPATOMA RNA ON THE RAT

Group	Route	Percentage of tumours	Mean time of appearance (days)	Percentage of regression

ribonucleic acids of animal origin in situations of enzyme deficiencies in man.

Supravital stainings such as acridine orange of tumour cells after 15-hr. incubation with liver RNA indicate viability of the cells after such treatment. Damage is also ruled out by the lack of effect of similar RNA preparations from other organs and from the tumour itself. Treatment of hepatoma cells with hepatoma RNA resulted in a wilder modification of the tumour. Within six days the tumour showed not only the usual large omental mass but also that this would extend to the liver, diaphragm, abdominal walls, whole peritoneal cavity, ovaries, intestines and into the pleural and pericardial cavities with a peculiar involvement of the thymus and the mediastinal and axillary lymph nodes. The thoracic involvement was noticed as extreme dyspnœa and cyanosis. In spite of all its wild features, this modified tumour regressed in a larger percentage than the unmodified variety.

In another experiment 50 animals received normal rat liver cells simply washed (group 1), treated by liver RNA (group 2) and treated by hepatoma RNA (group 3). The results are shown in Table 2. Tumours in group 3 consisted of slightly hæmorrhagic nodules deep-seated in the hilum and septa of the liver with scattered mural implantations. To test whether the results of the last experiments were due to a modification of the liver cells or to a direct effect of the tumour RNA this was injected intraperitoneally into adult rats, intravenously prenatal and subcutaneously neonatal. Controls consisted of normal liver RNA and buffered versenate saline (Table 3).

Of the controls injected with normal rat liver RNA, the prenatal and neonatal showed marked retardation of growth and stunting, but no tumours in the same period that the animals exposed to tumour RNA developed tumours. Eventually, the controls resumed normal growth and development while the experimental ones died of abdominal hæmorrhage.

These tumours extended throughout the peritoneal cavity, but serial sectioning of the liver and of the pancreas shows areas of possible primary tumour not found usually in the commonly transplanted hepatoma. Novikoff reports that the pancreas can be infiltrated by the tumour[8]. This causes the peritoneal implantations metastases, such as in the original Novikoff primary hepatoma. Interesting is the pancreas lesion, since liver and pancreas are two embryologically related organs. No thymus, lymph node or spleen involvement nor tumours of other localities were seen in these young. The possibility of malignant changes in liver cells induced by hepatoma RNA cannot be excluded. Niu[9] reports the formation of local tumours when normal mouse kidney cells were treated by RNA from ascites tumour cells. However, no attempt to produce this with RNA alone has been reported.

BLOOD NUCLEASES AND INFECTIOUS VIRAL NUCLEIC ACIDS

By ROGER M. HERRIOTT, JOHN H. CONNOLLY* and SHANTA GUPTA

Department of Biochemistry, The Johns Hopkins University School of Hygiene and Public Health,
Baltimore 5, Maryland

IT has been shown that animal viral nucleic acids can infect tissues[1-14] and that this is not blocked by antiserum against the intact virus[3,9,11]. Since nucleases in very low concentration destroy biologically active nucleic acids[15,16], an investigation of the deoxyribonuclease (DNAase)- and ribonuclease (RNAase)-levels in human blood was undertaken to decide their possible role against infectious deoxyribonucleic acid (DNA) or ribonucleic acid (RNA).

In the course of this investigation we encountered the liberation of both nucleases and their inhibitors from the cellular elements of blood as well as the formation of a DNAase inhibitor in serum. Analyses of these materials are included because they suggest explanations for changes in nuclease-levels that are otherwise difficult to understand.

Materials and Methods

Only an outline of procedures is given here. Detailed reports will appear elsewhere. Unless otherwise stated, all enzyme or inhibitor assays were performed at 37° C.

---

* Visiting Fellow from the Department of Microbiology, Queen's University Medical School, Belfast.

DNAase assay. The substrate of this enzyme was highly purified *Hemophilus influenzae* transforming DNA which can be assayed at concentrations as low as 10^{-6} μgm./ml. A concentrated solution of this DNA which confers streptomycin resistance on a susceptible strain of this organism was added to blood, blood products, or a solution of crystalline pancreatic DNAase (Worthington Biochemical Corporation, Freehold, New Jersey) dissolved in blood electrolyte solution at *p*H 7·4. The concentration of the transforming DNA in the digestion mixture was 1 μgm./ml. The blood electrolyte solution was made up following data by Bland[17] to which was added 10 μgm./ml. of crystalline bovine serum albumin (B.E.S.A.). Samples were withdrawn at intervals and assayed for residual transforming activity by the usual procedure[18]. The slope of a curve through such points was then used to get from a standard curve of an equivalent action by known concentrations of a crystalline preparation dissolved in B.E.S.A.

DNAase inhibitor (*DI*). DNAase inhibitor was determined by its action against a standard pancreatic DNAase solution analysed in the same manner. A dilution of the inhibitor which reduced the rate of destruction of transforming activity by 0·001 μgm./ml. crystalline DNAase in B.E.S.A. to one-half the control value was considered as containing 1 unit of DI.

RNAase assay. A concentrated solution of yeast RNA (Schwarz and Co., Mt. Vernon, New York) at *p*H 7·4 was added to blood, blood products, or solutions of crystalline pancreatic RNAase (Worthington Biochemical Corporation) in B.E.S.A., bringing the final concentration to 10 μgm./ml. At minute intervals samples were removed and the extent of digestion measured spectrophotometrically at 260 mμ on a filtrate after chilled perchloric acid precipitation of the undigested RNA. Blood-levels of RNAase were evaluated in terms of equivalent action by known concentrations of crystalline pancreatic RNAase (Worthington Biochemical Corporation).

RNAase inhibitor (*RI*) *assay.* RNAase inhibitor was assayed by its action against 0·1 μgm./ml. of crystalline RNAase. As with DNAase, the dilution of inhibitor which reduced the action of the standard enzyme solution to half its value was thought to contain 1 RI unit.

Blood, plasma and serum. Preliminary experiments, even in the absence of anticoagulants, gave variable results with whole blood, whereas consistent and otherwise similar results were obtained with the plasma. Assays were therefore made on plasma in the absence of anticoagulants, since the latter affect the DNAase. Samples were drawn freshly through silicone-coated ('Siliclad', Clay-Adams, Incorporated, 141 E. 25th St., New York 10, N.Y.) needles and syringes and introduced into chilled coated tubes; spun at 8,000 revolutions/min. for 5 min. and the nuclease-levels of the plasma evaluated immediately. Serum was prepared by allowing freshly drawn blood to incubate for 1 hr. at 37° C. after which the serum was drawn off, centrifuged when necessary and chilled or analysed immediately.

White blood cells (*WBC*). Blood drawn as above was centrifuged horizontally at 2,000 revolutions/min. for 10 min. The plasma was almost completely removed and used for the isolation of platelets. The WBC of the packed cell portion on standing 5–10 min. became mixed with the residual plasma. This was removed and diluted with B.E.S.A., the cells were centrifuged and, after a second washing, they were re-suspended in B.E.S.A.

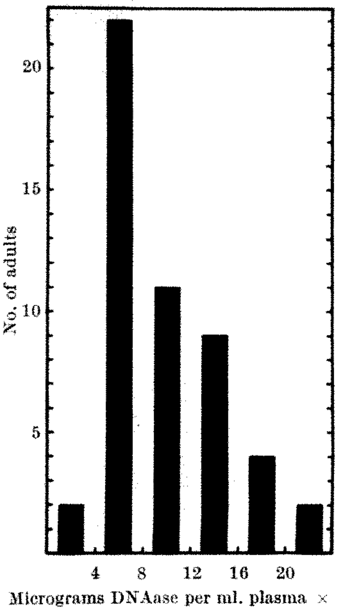

Fig. 1. DNAase-levels per ml. plasma of 50 normal adults

Disruption of cells. Each cell-type was suspended in a volume of B.E.S.A. to bring it to the concentration-level found in the blood. Disruption was obtained in 'Lusteroid' tubes placed in a 10-kilocycle Raytheon sonic oscillator. At full power (250 watts), disruption was essentially complete in 2·5 min. for platelets; 2 min. for WBC, and 10 min. for red blood cells (RBC).

Experimental Results

Nuclease-levels in blood of adults. Fig. 1 shows levels of DNAase in the plasma of fifty healthy adults (25 females and 25 males). Representatives of the coloured races are included. Evidence (not shown) that the inactivation of transforming DNA is probably due to the DNAase in blood is suggested by (*a*) a quantitative correlation between destructive rate and concentration of serum, and (*b*) an independent viscosimetric analysis of serum DNAase-level. Plasma was used regularly in place of whole blood with comparable results, considering the volume difference. From Fig. 1 it appears that the range of DNAase-level in plasma of human adults is 0·0003–0·002 μgm./ml. with an average of about 0·001 μgm./ml. and half these values per ml. of whole blood. The DNAase is Type 1 (ref. 19) since it has a digestion maximum near *p*H 7.

As noted earlier[20], blood DNAase depends on divalent cations for activity; hence it is inhibited by citrate, ethylenediaminetetraacetic acid (EDTA) and other chelating agents. In the present work heparin as an anticoagulant was avoided because as little as 40 μgm./ml. inhibited plasma DNAase, yet had no apparent effect on the pancreatic depolymerase. The literature is confusing in this regard since reports indicate that heparin inhibits pancreatic DNAase[21], does not inhibit the serum enzyme[22], and that it inhibits both[23]. Some features of the system not yet understood must be critical to this reaction.

The results in Fig. 2 suggest that the level of RNAase in the blood is equivalent to approximately 0·10 ±

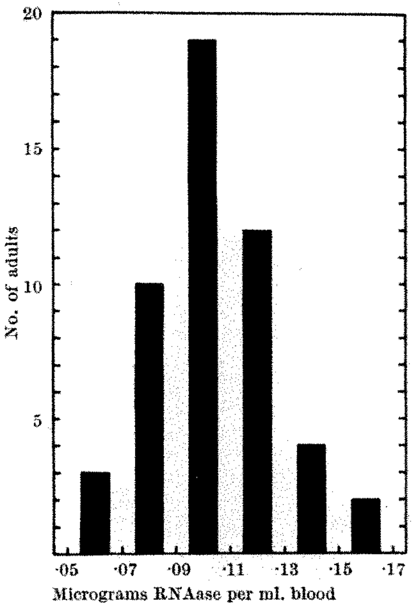

Fig. 2. DNAase-levels per ml. blood of 50 normal adults

0·05 μgm./ml. of crystalline pancreatic enzyme. Under the present conditions of study, the level of RNAase was not affected by clotting or manipulation. This result is somewhat lower than that reported earlier[2,26,27] for serum, even when correcting for the difference in volume.

Nucleases and their inhibitors in the formed elements. The DNAase activity of whole blood incubated at 37° C. decreased with time, suggesting the formation or liberation of an inhibitor. This, plus the observation that serum DNAase-levels were 2–6 times higher than the corresponding plasma-level, led to an analysis of isolated washed cellular components of blood sonically disrupted in B.E.S.A. The results are summarized in Table 1.

A sonicate of platelets contained a DNAase which could be activated by Mg^{++}. It was equivalent to 1×10^{-11} μgm. of crystalline pancreatic DNAase per platelet. These samples of blood with about 5×10^{8} platelets per ml. contain 5×10^{-3} μgm./ml. DNAase, or ten times as much as found free in whole blood, but nearly the same concentration as found in serum from clotted blood. It seems reasonable, though not proved, that the higher serum DNAase (see Table 1) arises from disruption of platelets during clotting, for the DNAase-level of serum from clotted cell-free plasma is not higher. It is somewhat lower due, perhaps, to adsorption of the enzyme to the clot.

Table 1. Average Levels of Nucleases and their Inhibitors in Blood and Certain Blood Fractions

System	DNAase μgm./ml.	RNAase μgm./ml.	DNAase inhibitor units	RNAase inhibitor
Whole blood, fresh	0·0005 ± 0·0002	0·1 ± 0·05		
Plasma, fresh	0·001 ± 0·0004	0·2 ± 0·1		
Serum, fresh (from clotted whole blood)	0·006	0·2		
Serum (clotted cell-free plasma)	0·0003			
Platelets (blood concentration)	0·005			
WBC (blood concentration)	0·0	0·1	300	
RBC (blood concentration)			350	10
Serum heated at 56° C. 0·25 hr.		0·2	2	
Serum at 37° C. 15 hr.			3	
Serum + 0·01 *M* Mg^{++} 1 hr.		0·2	100	

The presence in white blood cells of a powerful DNAase inhibitor had been known[24,25]. In the present system 1 : 300 dilution of the sonically disrupted WBC at a concentration found in whole blood, reduced the DNAase activity of a standard enzyme preparation to one-half. So, by definition, the WBC at blood-level contains 300 DI. Much of this inhibitor is released into the medium on incubation at 37° C., which may be responsible for the observed variations in enzyme-levels.

Similar sonicates of WBC contain RNAase, and it has been suggested that white blood cells are the source of serum RNAase[26].

Inhibitors of both nucleases were found in the solutions of disintegrated, washed red blood cells. Expressed in units defined in the section on Methods there were 350 DI and 10 RI per ml. of RBC at the blood-level concentration.

Formation of DNAase inhibitor in serum. As noted earlier, the level of DNAase in fresh serum is several times higher than that in plasma, yet, under certain conditions, this activity is lost and it seems that an inhibitor is formed in the serum. Previous workers[20,22] had noted a loss of DNAase on heating but had offered no explanation. Since the heated serum will inhibit added pancreatic DNAase, an inhibitor for this enzyme would appear to have been formed. The conditions favouring inhibitor formation are (*a*) incubation overnight at 37° C., (*b*) incubation at 37° C. for 1–2 hr. after addition of 0·01 *M* Mg^{++}, or (*c*) heating at 56° C. for 15 min. The levels of inhibitor formed are shown in Table 1. The loss of enzymic function was not due to a loss of Mg^{++} activator, for addition of the latter brought about no restoration of activity. It is difficult to account for the difference between the present results showing formation of inhibitor at 37° C. and the reported[28] destruction of pancreatic DNAase inhibitor at 35° C.

Discussion

It seems reasonable to suppose that tissues undergoing a viral infection contain free viral nucleic acid as well as complete virus, and both these would be liberated at some stage of the infection. While complete virus can be rendered non-infectious by antibodies, the infectivity of the nucleic acid is apparently not reduced by this mechanism[3]. One wonders if the nucleic acid phase continues to spread the infection even if less effectively, or if there is another physiological defence against this phase as well.

The present work, which is confined to blood, shows that healthy human adults have nucleases which destroy biologically active nucleic acids of both types, and the question comes down to one of competing rates, that is, the rate of enzymic destruction versus the rate of infection, and the decision will be determined by the concentrations of nuclease, viral nucleic acid and the number of susceptible cells.

Work on the infectivity of viral RNA shows that normal serum destroys infectivity[1,3,6], and this destructive power is attributed to the RNAase[3]. The present results support this conclusion, for RNAase activity is found in serum.

The rate of destruction of transforming activity by pancreatic DNAase in B.E.S.A. is about 170 logarithmic units per minute per microgram of crystalline enzyme. From results presented here, there is only 5 × 10^{-4} µgm. of DNAase per ml. of blood in the average healthy human being ; hence, destruction will go on at the rate of about 1 logarithmic unit per 12 min., that is, 90 per cent destruction in 12 min. There is too little information on the minimum time necessary for infection in human viral diseases, especially for the naked nucleic acid phase, to draw a firm conclusion about blood DNAase as an effective defence against infectious DNA. But general considerations from work on tissue cultures[3,24] and bacterial transformations[30-32] suggest that infection of susceptible tissues by a viral nucleic acid takes place in a few minutes or less.

Schramm and Gierer[16] reported the destruction of infectivity of tobacco mosaic virus RNA by crystalline pancreatic RNAase at 8° C. Applying the usual temperature coefficient for enzyme-catalysed reactions (2 per 10 deg. C.) leads to a value for the rate of destruction at 37° C. of about 300 logarithmis units per min. per microgram of crystalline RNAase. A blood level of 0·1 µgm./ml. of RNAase would then be expected to destroy the infectivity of free RNA at the rate of 30 logarithmic units per min. per ml., or 0·5 logarithmic units per sec. Whether this is rapid enough to prevent infection is a matter for conjecture, but it is about one hundred times faster than the rate at which DNAase destroys DNA. In this connexion it should be recalled that infections are produced in animals with viral nucleic acid. Thus both RNA[4,6,8] and DNA[13] have produced infections, and in at least one case the route of infection was significant[6]. It is possible, however, that these laboratory infections developed only because relatively high levels of nucleic acid were inoculated and that the nucleases and other counteracting forces eliminate the low levels of nucleic acid that appear during the natural disease.

The experience of many virologists in completely neutralizing sera from those human beings who are ill with viral infections cannot be used as an argument against the existence of a nucleic acid phase, for the time consumed in preparing the sera and the increased DNAase-levels of serum could well militate against detection of any nucleic acid originally present in the donor's blood.

The presence of DNAase in platelets and its inhibitor in white blood cell, red blood cell and serum probably explains the wide variations in reports on blood or serum concentrations of this enzyme[20,22,34]. The RNAase in white blood cells and its inhibitor in red blood cells are not sufficient to lead to any appreciable variation in RNAase-levels in ordinary circumstances. Perhaps the wide fluctuations in DNAase-levels and its inhibitor, compared with the relatively constant level of RNAase, are due to the extremely low normal level of DNAase. The release of quite small quantities of either the enzyme or its inhibitor produces large changes in the blood level of this enzyme.

Some variations in the levels of these enzymes in the blood of sick individuals will be the subject of another communication. A few analyses of blood from individuals suffering from serum hepatitis showed no depressed levels of blood nucleases. In this anomalous disease, which prompted the present work, the long incubation and carrier periods[35] suggested a non-antigenic agent and hence, possibly, viral nucleic acid. These preliminary analyses, even if substantiated, do not exclude the possibility of a free viral nucleic acid from being important in this disease; they merely show no alteration in the nuclease-level.

An assumption, not yet tested, is involved in this work and it deserves to be mentioned. Implicit in the quantitative analysis is the assumption that the viral nucleic acids would exhibit the same response to nucleases as the arbitrarily chosen substrates. There are few data for comparison, except for experiments in which poliomyelitis RNA[3] was used. In this case, it was found that monkey serum contains RNAase equivalent to about 0·6–5 µgm./ml. of crystalline pancreatic RNAase, and species differences can be considerable[36].

Finally, it may be worth noting that the usual means of preserving blood or blood products, especially the use of chelating agents such as citrate as anticoagulant, will preserve viral DNA in an infective state by tying up the divalent cations needed for DNAase action, and methods such as heating to 60–65° C., designed to sterilize certain blood fractions, do not destroy the biological properties of DNA[37].

PHYSICS

The Bertele Arc

THE electron emission in the cathode spot of arcs has remained an unexplained phenomenon since K. T. Compton[1] first directed attention to it. It appears that the arc discharge discovered by H. von Bertele[2] puts this paradox into an even more acute form.

In this discharge the cathode is a polished, water-cooled thimble of molybdenum, which first must be processed in a way which suggests the formation of a very thin layer of amalgam. The molybdenum thimble is kept in contact with a small pool of mercury. The cathode spot first runs freely about on the surface of the mercury pool, but it soon becomes attached to the boundary-line between molybdenum and mercury, on which it forms what appears as a luminous line. During further processing the cathode, spot gradually spreads over the molybdenum surface until it appears to cover it completely. In this operation a faintly luminous glow covers the cathode and to the eye the discharge has all the appearance of a glow discharge, while electrically it can scarcely be distinguished from an arc. The cathode drop is about 10 V., up to the highest currents which we have investigated, which were about 30 amp. on cathodes of about 1 $cm.^2$ area. The paradoxical feature of the phenomenon is the small drop in voltage, in combination with a current density which is many orders of magnitude higher than could be obtained in a glow discharge.

We have now further investigated the nature of this striking phenomenon by two lines of experiments: cinematographic observations and measurement of the current fluctuations. It was natural to suspect that the apparently steady and uniform discharge was simulated by smaller cathode-spots running about at high speed. This was in fact revealed by high-speed photographs, for which we are obliged to the Rectifier Department of the General Electric Co., Wembley. In the photographs shown, taken with an exposure of 1/15,000 sec. at intervals of 1/3,000 sec. of a cathode of about 1 $cm.^2$ area, at a current of 15 amp., the luminous glow filled at any time only about 1/10 of the cathode area. The glow has a complicated ramified appearance, and greatly changes its shape and position in intervals of 1/3,000 sec., but its area appears to remain approximately constant so long as the current is constant, and appears to increase proportionally to the current. In other words, judging from these photographs it appears that we have to do with a 'normal glow discharge', but with a current density about 150 $amp./cm.^2$ which is at least six orders higher than in the normal glow at such low pressures, though four orders lower than the current densities observed by Froome[3] in cathode spots on pool cathodes.

If this is the correct interpretation of the photographs, it appears that the cathode spot jumps rather than moves steadily from position to position, as its outlines remain remarkably sharp in photographs taken with an exposure of about 1/5 of the picture interval. It does not appear though that this violent motion is necessary for the existence of the spot. On the cylindrical mantle of the thimble one can observe in the photographs several small spots of which one has remained stationary for 1 millisecond, and in other photographs we have observed spots which were steady over periods ten times as long.

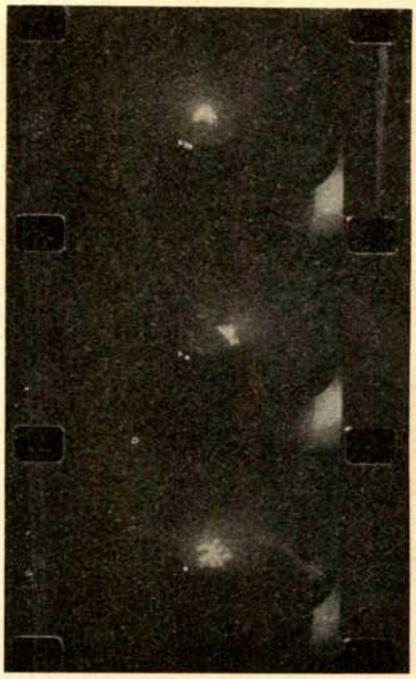

Fig. 1. Sequence of three photographs of the cathode spot in a Bertele discharge, at a picture-rate of 3,000/sec., exposure 1/15,000 sec. The cathode is a water-cooled molybdenum thimble with a blunt conical top and cylindrical shaft of 1 cm. diameter which is surrounded by an annular groove in an insulator, containing mercury during the forming, but empty during operation. Current, 15 amp.

There is, however, another possible interpretation. This is that the apparently large, diffuse spots are simulated by a number of much smaller very bright spots, running about at high speed in a restricted area, which changes from time to time. One could even assume that these spots are not essentially different from those on pool cathodes, because they are running about on a monatomic film of mercury which they rapidly evaporate. Such a hypothesis would not be absolutely contradicted by the small steady spots, because one could imagine the monatomic mercury film rapidly flowing into them from the periphery.

Unfortunately, we had no equipment available for repeating these observations at currents about 150–200 amp., at which the 'glow hypothesis' would predict that the whole surface of the cathode is permanently covered and the voltage drop would have to rise rapidly; nor could we repeat the experiment with a higher time resolution, which might have shown up the hypothetical smaller spots. We are inclined though to believe that the 'glow interpretation' is nearer to the truth, on the basis of our second line of experiments, on the fluctuation spectrum of the arc current.

We have measured the power spectrum of the current in the frequency range from a few hundred cycles to one megacycle. In the range up to 50 kilocycles the noise-power is flat; beyond this there is a rapid fall-off with a cut-off at about one megacycle. Quantitative analysis shows that the spectrum could be accounted for by the superposition of random bursts each with the discharge of only about one million electrons. The fall-off with frequency leads to the conclusion that these bursts have a duration of certainly not less than 1 microsecond, but in most cases 10–100 times more. This is, roughly speaking, the time for which the cathode spots have been observed to be apparently steady in the high-speed photographs. The noise measurements are therefore compatible with the assumption that what we see in the photographs are real diffuse spots, steady for perhaps 0·01–0·1 millisecond. They are scarcely compatible with the explanation in terms of much smaller spots, moving about at high speeds. One could expect such small spots to cross their own path, and those of others, fairly often before the mercury film has re-established itself, and this would lead to rapid breaks in the current, which ought to have revealed itself as high-frequency noise.

The provisional conclusion from these experiments therefore appears to be that though the Bertele discharge is not an even, uniform glow, and at any time covers only a part of the cathode area, its current density is not likely to be much more than a few hundred amp./cm.[2], and is probably steady over times of the order of at least 10 μsec. The experiments therefore suggest that cold metal cathodes can emit electron currents of this order, with macroscopic electric fields far too small to account for field emission, without high-pressure vapour jets, and with an ion current which is probably not more than a few per cent of the electron current. We do not propose a physical explanation of this phenomenon. We only note that the observations would be compatible with elementary discharges caused each by a single ion, breaking down the barrier over an area of some 10 Å. square only, provided that an ion can linger at a distance of a few Å. before the cathode surface for several microseconds, in a sort of metastable state of high energy. There is, of course, at present no theoretical support for such a contention.

We are indebted to Dr. A. Robson, Harwell, for a critical discussion of the experiments.

Diffusion of Small Molecules

THE diffusion coefficient of a particle in solution is given by the Einstein equation[1]:

$$D = \frac{kT}{f} \tag{1}$$

where f is the frictional coefficient of the diffusing substance.

For spherical and rigid particles, large compared with molecules of the solvent, Stokes found[2]:

$$f = 6\pi\eta r$$

By introducing this relationship into equation (1) one obtains the Einstein–Stokes equation:

$$D = \frac{kT}{6\pi\eta r} \tag{2}$$

where η is the viscosity of the solvent, k the Boltzmann constant and r the radius of the diffusing sphere.

For spherical, but very small particles, Basset[3] has found the expression:

$$f = 6\pi\eta r \frac{\beta r + 2\eta}{\beta r + 3\eta}$$

where β is an empirical factor called 'coefficient of sliding friction' that ranges from zero to ∞. This introduces into equation (2) a correction factor ranging from 3/2 to 1.

Basset's equation has not yet been verified experimentally, however. Sutherland[4] carried out some diffusion measurements on alcohols and other organic substances and found that, for small molecules, the product Dr is greater than that calculated with equation (2) and decreases toward a constant value as the dimensions of the diffusing molecules increase. He considered that his measurements support the correction introduced by Basset.

This comparison is arbitrary indeed, if we consider that the model used by Stokes and Basset for their calculations is very different from a diffusing molecule, especially if it is linear instead of spherical, like alcohols and several other organic substances.

For diffusion measurements on linear and flexible molecules, we have found that, in some cases, equation (2) is verified if we substitute for r the gyration radius of the diffusing molecule to which is added the thickness of the atomic groups —CH_2— or —OH— constituting the molecule (that is, the radius corresponding to the action field of these groups). We have found that in these cases such thickness is 0·95 Å. We shall call s the sum of the gyration radius and the atomic thickness; for calculations refer to our earlier papers[5,6]. We have stated that: (*a*) when solute molecules are large compared to those of the solvent, as in the case of water solutions of organic molecules or for benzene solution of polymers, equation (2) is valid; (*b*) when solute molecules are of the same size as those of the solvent, as for benzene solutions of alcohols, esters and hydrocarbons, the radius calculated by equation (2) is smaller than the theoretical gyration radius s. The difference becomes greater when the solute and the solvent sizes are similar, and approaches zero with increasing dimensions of the solute.

Even if there is not as yet any theory relating the diffusion coefficient to the gyration radius, it is, however, interesting to note that in two cases at least, when the ratio of the dimensions of solute and solvent is great enough, equation (2) can be applied. We can, therefore, argue that a theory founded on a more realistic model should give an expression similar to equation (2).

We have used this expression to calculate the gyration radius of linear polymers in benzene, obtaining values agreeing with results using other methods[7].

In this communication we discuss some measurements carried out in the case where equation (2) is not valid, that is, when solute molecules are smaller, equal to or a little larger than those of the solvent. We have found that in this range the values of r (calculated by equation (2) from the measured values of D) are smaller than the values of s, calculated from the molecular structure.

We shall introduce the ratio s/r as a parameter to study that behaviour. Such a ratio in the case of spherical particles of Stokes's model corresponds to the correction factor calculated by Basset.

Measurements of diffusion coefficient were carried out in two solvents at 20 ± 0·01° C. by means of a method described before[6]. The precision of measurement was 0·5 per cent and the reproducibility about 1–2 per cent.

The products used were from the best firms, purified when necessary and identified by chromatographic analysis, refractive index and melting point.

The solvents were benzene and n-heptane; for the former we have assumed the value $s_{0,1} = 2{\cdot}35$ Å. $(1{\cdot}4 + 0{\cdot}95)$ and for the latter $s_{0,2} = 3{\cdot}0$ Å. $(2{\cdot}05 + 0{\cdot}95)$.

For the measurements in benzene see ref. 5; we list the measurements for n-heptane in Table 1.

Table 1

Substances	$D \times 10^7$ (cm.²/sec.)	r (Å.)	s (Å.)	s/r
n-Decane	206	2·50	3·50	1·40
n-Tetradecane	165	3·12	4·06	1·30
n-Octadecane	146	3·53	4·53	1·28
n-Octacosane	108	4·78	5·51	1·15
n-Dotriacontane	100	5·16	5·83	1·13
Methylcaprate	204	2·52	3·50	1·39
Methylcaproate	182	2·83	3·80	1·34
Ethyl ether	285	1·81	2·44	1·34
Dimethylketone	312	1·65	2·05	1·24

Fig. 1 shows values of s/r, measured in the two solvents, as a function of s.

We note that both behaviours are similar. In either case the values of the ratio rise to a maximum and then approach 1 asymptotically for high values of s. This confirms that equation (2) is useful for calculating the gyration radius of high molecular weight molecules like polymers with good precision, perhaps the best among the methods known nowadays. It is very interesting to point out the existence of a maximum in both cases; it was perhaps unexpected that, in a range before the maximum, smaller molecules diffuse more slowly than large ones. It is remarkable that in both cases the abscissa of the maximum is approximately the value of the gyration radius of the solvent (about 2·35 for benzene and 3 for n-heptane). A change in the rate of diffusion occurs when the solute molecules reach the dimensions of the solvent. In other words, molecules smaller than solvent molecules diffuse slower the smaller they are, while solute molecules larger than those of the solvent behave according to the Einstein–Stokes equation.

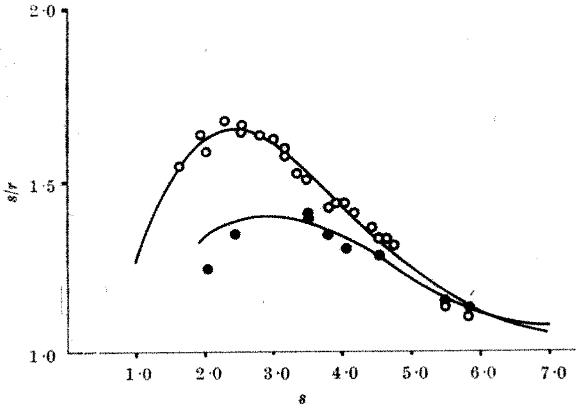

Fig. 1. ○, Measurements in benzene; ●, measurements in n-heptane

These facts are certainly related to the structure of the liquid state and to the diffusion mechanism. Therefore we think that our measurements and results can provide an interesting basis for theoretical work.

It would be useful to extend the measurements to a greater number of solvents and solutes, but, for the moment, we have limited our studies to the above cases owing to the difficulty of finding proper solvents and solutes.

We have also tried to find an empirical relation which predicts experimental results. In previous work[5] we have written an equation, very easy to apply, which accounts only for the latter part of the curve for benzene solutions and was therefore insufficient from a general point of view.

The distribution of the points and the presence of a maximum make us foresee an exponential behaviour. By trial we have found the relations:

$$s/r = 1 + 0{\cdot}90\, s^3 \exp(-1{\cdot}23 s) \quad \text{for benzene}$$

$$s/r = 1 + 0{\cdot}33\, s^3 \exp(-1{\cdot}04 s) \quad \text{for } n\text{-heptane}$$

which are shown as full lines in Fig. 1. As we see, they agree sufficiently with experimental values.

We have tried to formulate a single expression which includes these relationships by using as a parameter the dimension s_0 of the solvent molecules.

The two relationships may be written in the general way:

$$s/r = 1 + A_1 s^3 \exp(-B_1 s)$$
$$s/r = 1 + A_2 s^3 \exp(-B_2 s)$$

We have to examine whether there is a relationship between the two constants A_1 and B_1 of benzene, A_2 and B_2 of n-heptane and the dimension s_0 of the solvent molecules.

We have found that we can write:

$$A = A_1 s_{0,1}^4 = 27{\cdot}4 \qquad B = B_1 s_{0,1} = 2{\cdot}89$$

$$A = A_2 s_{0,2}^4 = 26{\cdot}7 \qquad B = B_2 s_{0,2} = 3{\cdot}12$$

The two values of A and the two of B are so close as to be considered two constants independent of s_0. This agreement is satisfactory if we take into account that the values found depend on precision of measurement of the diffusion coefficient and on the theoretical calculation of the gyration radius.

We can therefore suggest a parametric relation:

$$s/r = 1 + (A/s_0^4) s^3 \exp(-B/s_0) s$$

where A has a value of about 27 and B a value of about 3.

Anomalous Conductivity and Lorenz Parameter in Dilute Silver–Manganese Alloys at Low Temperatures

Low-temperature electrical resistivity measurements by Gerritsen and Linde[1] on silver alloys containing small amounts of manganese in solid solution showed that, instead of attaining a temperature-independent 'residual' resistivity, they presented a minimum somewhat below liquid-hydrogen temperatures, followed by a maximum at still lower temperatures.

Measurements of the thermal conductivity (λ) of three dilute silver–manganese rods containing respectively 0·55, 0·32 and 0·14 atoms per cent of manganese revealed[2,3] an anomalous behaviour at liquid-helium temperatures in a zero magnetic field. This anomaly consisted in the $\lambda : T$ curve exhibiting a 'knee' at about 2·7° K., so that the values of λ below the knee were higher than would result if the curve above the knee were simply extended to the lower temperatures. The $\lambda/T : T$ curve exhibited this anomaly in the form of a 'dip' followed by a 'hump' at the lowest temperatures[2,4].

Since the shape of the $\lambda : T$ curve was not significantly altered by magnetic fields as high as 25 kilogauss, it was suggested that the zero-field thermal conductivity anomaly might be due to an extra contribution to the lattice thermal conductivity, owing probably to a partial uncoupling of the longitudinal and transverse phonons[2,5]. However, it was not understood why the $\lambda/T : T$ curves 'dipped' below the normal rectilinear behaviour, at temperatures between about 2·5 and 5° K. (Fig. 2, in ref. 4).

It has now been possible to analyse the thermal and electrical conductivity data on these alloys, in magnetic fields and in zero field, by the method of Gruneisen–de Haas[6]. The plots of $\lambda_{[H]} : \sigma_{[H]}T$ at any temperature (where $\lambda_{[H]}$ and $\sigma_{[H]}$ are the values of the thermal and electrical conductivities for different values of the transverse magnetic field H, including $H = 0$) can be considered as straight lines. This means that the electronic Lorenz parameter L_e seems to be independent of the magnetic field-strength. However, it exhibits also an interesting variation with temperature. It is found that, in these alloys, at liquid-helium temperatures: (1) L_e is less than the 'normal' Sommerfeld value ($2 \cdot 45 \times 10^{-8}$ watt-ohms-deg.$^{-2}$), but approaches that value at about 1° K. or lower; (2) L_e has a minimum value at a temperature $T_{\text{min.}}$; (3) $T_{\text{min.}}$ varies with the manganese content c, shifting to a higher temperature with increasing c, and (4) the depth of the minimum is reduced with increase of c.

The fact that L_e is less than the Sommerfeld value at liquid-helium temperatures accounts for the 'dip' in the $\lambda/T : T$ curves for these alloys, between about 2·5 and 5° K.

Full details will be published elsewhere.

Grateful acknowledgment is made of the benefit of discussions with the director, Sir K. S. Krishnan.

Aggregation and Dispersal of Radiation Damage in Graphite

Following pioneering work by Grenall[1], Williamson[2] has used the technique of transmission electron microscopy to elucidate some aspects of the behaviour of dislocations in natural crystals of graphite, and Amelinckx and Delavignette[3] have demonstrated the formation of vacancy loops in quenched material. We have repeated some of these observations and applied the method to the study of neutron irradiation damage and its behaviour in crystals annealed up to 2,500° C. Our results appear to be consistent with those of Bollmann[4], who obtained photographs of defects in artificial graphite annealed up to 400° C.

Crystals of natural graphite obtained from Ticonderoga calcite were irradiated in the high-flux reactors *Dido* and *Pluto* to doses of about $4 \cdot 8 \times 10^{20}$ neutrons per sq. cm. (~500 equivalent megawatt-days per tonne (of fuel)) at various temperatures in the range 150–650° C. It was found advisable to give the crystals a purifying heat treatment at 1,500° C. before irradiation. Even then, however, the unirradiated material showed some flaws, including lenticular formations with diameters in the range 0·1–3μ similar to those first seen by Rang[5] in mica. Specimens were prepared by repeated cleavage using adhesive tape, and were examined in a Siemens Elmiskop microscope at 100-kV. anode voltage.

The general behaviour of the damage effects seen is illustrated in Figs. 1 and 2, which are on a scale of 120,000 : 1. The material of Fig. 1*a* was irradiated at 200° C. and the damage is present as very fine speckling, barely resolved but quite clear in the neighbourhood of an extinction contour. The light and dark contrast is of no particular significance, as the same feature changes from one to the other when the contour is moved by tilting the specimen. At higher temperatures, damage sites are larger, rounder and more sparse, as illustrated in Fig. 1*b*, which was obtained by irradiation at 650° C. Dislocations have not been found on material irradiated at the lower temperatures and are difficult to see on material irradiated at the higher temperatures. Dark-field images show no additional features.

Annealing of the low-temperature damage causes the defects to form clusters, the effect becoming marked at about 1,000° C. as shown in Fig. 1*c*. The clusters

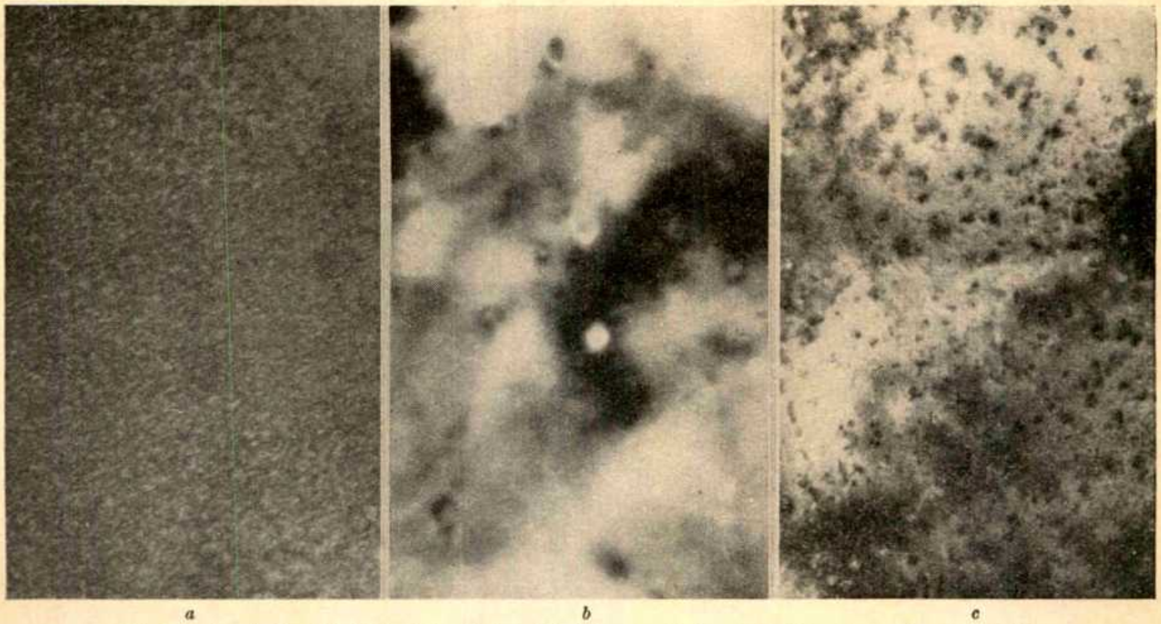

Fig. 1. *a*, Irradiation at 200° C.; *b*, irradiation at 650° C.; *c*, irradiation at 200° C. and annealing at 1,000° C.

appear to be very complex, and they are very irregular in shape, each one being apparently made up of a number of smaller units which are probably in different planes. It is possible that these clusters are formed by the migrations of smaller groups, but more likely that they are formed by the preferential growth of some sites as the less-stable ones break up. The process continues up to 1,500° C., as illustrated by the large clusters in Fig. 2*a*. Sometimes these large clusters align themselves in particular directions, as shown in Fig. 2*b*; but these directions have not been found to correspond to any particular crystal lattice vector as tested by the local electron diffraction pattern. They are therefore assumed to be associated with a local dislocation array. A few examples have also been found of alignment on parallel smooth curves. In other regions, the clusters spread out roughly along the hexagonal sides of a 'chicken-wire' pattern, as in Fig. 2*c*, suggesting that possibly ascertainable fields of force exist between complexes.

Damage incurred at 150° C. begins to disappear rapidly at annealing temperatures above 1,500° C. At 1,550° C., many of the larger clusters have been broken up, and at 1,700° C. there is little evidence of damage except a possibly enhanced dislocation density. Specimens annealed at higher temperatures are indistinguishable from unirradiated material, but there is some evidence that material irradiated at 200° C. requires slightly higher temperatures for complete annealing.

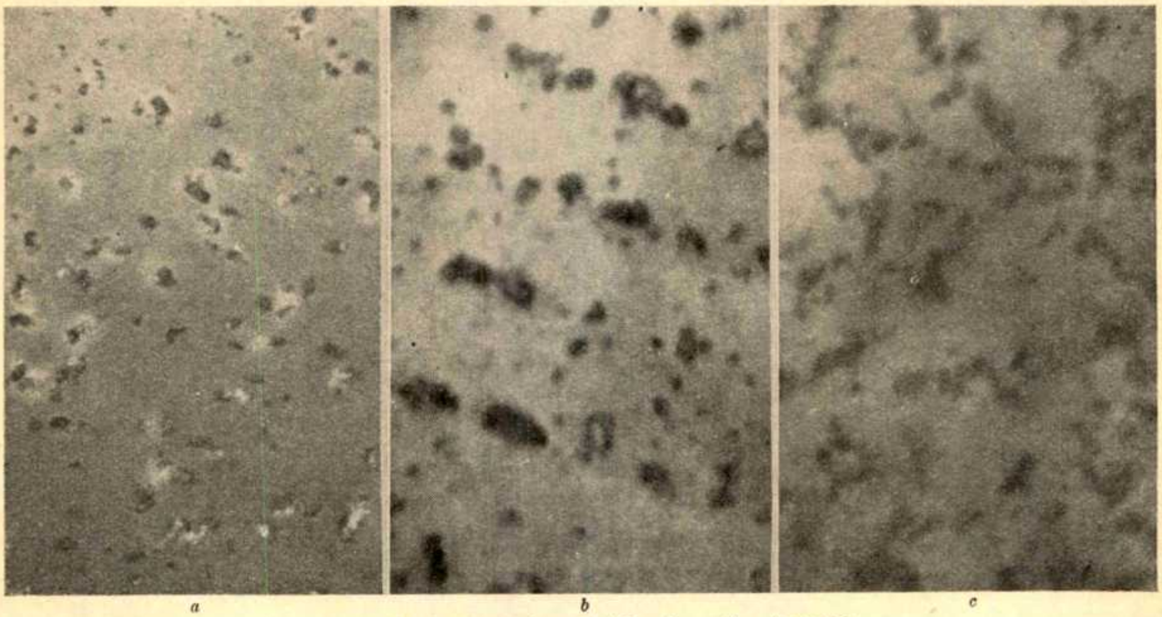

Fig. 2. *a*, *b* and *c*, Irradiation at 200° C. and annealing at 1,500° C.

It is not yet possible to say definitely whether the damage seen is predominantly due to interstitial atoms or vacancies, or if both kinds of defect are involved. However, interstitials are thought to be more mobile at least up to 1,000° C., and the general behaviour does not seem to correspond to that of vacancies as described by Amelinckx and Delavignette[3], so that it may be assumed provisionally that the effects constitute a direct observation of the behaviour of interstitial clusters.

General studies of neutron-irradiated graphite (see, for example, Simmons[6]) have already suggested the formation of highly stable complexes by the annealing of low-temperature damage, and more detailed studies will now be possible. The rapid disappearance of defects above 1,500° C. corresponds well with the final annealing of electrical effects observed in unpublished work by Eatherly.

We wish to thank Messrs. J. H. W. Simmons and R. S. Barnes for their interest and encouragement.

GEOPHYSICS

Auroral Observations at Halley Bay, Antarctica, during 1959

IN accordance with the recommendations of the Special Committee on Antarctic Research the programme of auroral observation conducted during the International Geophysical Year at Halley Bay, Antarctica, was continued into 1959. The Halley Bay Base, established by the Royal Society International Geophysical Year Expedition and now administered by the Falkland Islands Dependencies Survey, is situated in geomagnetic latitude 66° S., and both visual and all-sky camera records are now available for the four years 1956–59. A detailed analysis of the results of the first three years observations has appeared elsewhere[1], and it is interesting to compare these results with those obtained during 1959.

Of particular interest is the apparent change in the position of the southern auroral zone over the course of the four years which includes the period of sunspot maximum in 1957. Previously[2] the position of a 'quiet arc zone' has been defined in terms of the median value and interquartile range of the latitudinal distribution of quiet arcs. Such a distribution has now been obtained using the results of the 1959 observations; the positions of the quiet arc zone for the four consecutive years are given in Table 1.

Table 1

Year	1956	1957	1958	1959
Median latitude (°S. geomagnetic)	70·8	71·8	71·9	71·0
Interquartile range	±1·3	±1·0	±1·0	±1·1

Paton[3] has recently suggested that there may be a simple geometrical connexion between the position of the quiet arc zones in the two hemispheres and the 'horns' of the Van Allen belts of geomagnetically trapped radiation. The changes in the character of these belts during the period July 1958–August 1959[4] are certainly in keeping with this proposal.

METALLURGY

Theory of the Deformation and Fracture of Body-centred Cubic Transition Metals

EXPERIMENTS on a number of body-centred cubic transition metals[1] have shown that, above the ductile–brittle transition temperature, the yield stress, σ_y, varies with the average grain diameter, $2d$, according to the relation:

$$\sigma_y = \sigma_i + k_y d^{-1/2} \qquad (1)$$

Below the transition temperature, the brittle fracture stress, σ_f, is related to the grain size by the similar relation:

$$\sigma_f = \sigma_i + k_f d^{-1/2} \qquad (2)$$

Cottrell[2] has developed a theory of the ductile–brittle transition in terms of the parameters σ_i and k_y. According to the model adopted by Cottrell, σ_i is a lattice friction stress which contains a temperature-dependent part tentatively attributed to the Peierls–Nabarro stress of the lattice. The grain size parameter, k_y, is related to the stress, σ_d, required to unpin a dislocation from its impurity atmosphere and is given by the equation:

$$k_y = \sigma_d l^{*1/2} \qquad (3)$$

where l^* is the average distance from a grain boundary to the nearest dislocation source. In developing his theory Cottrell found that for a specimen to be brittle the criterion:

$$(\sigma_i d^{1/2} + k_y)k_y \geqslant \beta\mu\gamma \qquad (4)$$

must be satisfied. Here β is a constant which is nearly unity, for uniaxial tension, μ is the rigidity modulus, and γ the effective surface energy for fracture. The relations between the brittle fracture stress, the stress for ductile cleavage fracture, $\sigma_{f'}$, and the grain size which he obtained were:

$$\sigma_f(\sigma_f - \sigma_i)d = \beta\mu\gamma \qquad (5)$$

and

$$\sigma_{f'} = \frac{\beta\mu\gamma}{k_y} d^{-1/2} \qquad (6)$$

These equations appeared, at the time that the theory was formulated, to agree with most of the available experimental results, although no adequate results existed to test equation (6). Equation (5) is not significantly different from equation (2) over the ranges of grain size and temperature so far studied.

Recent experimental work in this laboratory and elsewhere has revealed several inadequacies in the theory of which three will be considered. First, a set of measurements on molybdenum at − 78° C. (ref. 3) has shown that the dependence of ductile cleavage fracture stress on grain size is not correctly described by equation (6). Secondly, it has been found that the value of k_y for niobium is very small or zero at all temperatures[1]. This suggests, from equation (3), that the dislocation locking in niobium is very weak. On the other hand, sharp yielding is observed in niobium up to about 400° C. (ref. 4), and this suggests that the locking is at least as strong as in iron. Thirdly, since k_y is proportional to the unpinning stress, it should be strain-rate sensitive, whereas a recent set of measurements on iron and steel[5] have shown that it is not.

In order to explain these discrepancies between the experimental results and Cottrell's theory, I have found it necessary to develop a modified form of the theory. This has involved a re-interpretation of the parameters σ_i and k_y. Since a full account of this theory will be published elsewhere, only an outline of the main conclusions reached will be given here.

It has been established that the parameter σ_i is the sum of two terms, $\sigma_i(\mathrm{I})$ and $\sigma_i(L)$, that is :

$$\sigma_i = \sigma_i(\mathrm{I}) + \sigma_i(L) \qquad (7)$$

where $\sigma_i(\mathrm{I})$ is a lattice friction stress due to impurities and $\sigma_i(L)$ is the stress required to propagate a Luders band through a single crystal having no lattice friction stress. The term $\sigma_i(L)$ is a function of the unpinning stress, σ_d, and of the work-hardening properties of the metal, and it is therefore strongly temperature dependent. The Peierls–Nabarro stress does not contribute significantly to σ_i. The parameter k_y is a measure of the work-hardening which occurs near grain boundaries during the propagation of a Luders band in a polycrystal. It is determined mainly by the work-hardening properties of the metal, but is also influenced by the unpinning stress, σ_d.

The treatment of brittle fracture and the ductile–brittle transition given in the theory is based on the observation that, at and above the transition temperature, a growing microcrack is unable to penetrate the region of forced slip near the boundary of the grain in which it is nucleated. The criterion for brittle–fracture is then :

$$\sigma_i + k_y d^{-1/2} + \Delta\sigma \geqslant \sqrt{\frac{2\gamma_e E}{\pi(d - d_0)}} \qquad (8)$$

Here $\Delta\sigma$ is the magnitude of the yield drop, γ_e is the effective surface energy for fracture, E is Young's modulus, and d_0 is the distance from the tip of an arrested crack to the grain boundary. The values of γ_e calculated from equation (8) vary from metal to metal and for a given metal depend on grain size. They lie in the range $8{\cdot}5 \times 10^3$ to $6{\cdot}5 \times 10^5$ ergs cm.$^{-2}$.

The interpretation of these values of γ_e leads to the conclusion that for a body-centred cubic transition metal to be relatively brittle it must have both strongly locked dislocations and a high work-hardening rate. The transition temperature comes out to be roughly independent of grain size for brittle metals, such as tungsten and molybdenum, but strongly dependent on grain size for relatively ductile metals, such as niobium and steel.

The theory has also been used to reinterpret existing experimental results on the hardening and embrittlement of mild steel[6] and molybdenum[7] by neutron irradiation. It is found that, as a result of irradiating mild steel near room temperature, both the friction stress, $\sigma_i(\mathrm{I})$, and the unpinning stress, σ_d, increase. In the case of molybdenum, only σ_d increases significantly. The deviation from equation (1) shown by irradiated molybdenum is shown to be the consequence of a combination of a particularly high unpinning stress and a high work-hardening rate. The theory predicts that the increase in transition temperature caused by irradiating mild steel should be greatest in specimens having a fine grain size, and that for large neutron doses the transition temperature should become independent of grain size.

CHEMISTRY

Electronic Properties of Phenazine

MANY organic compounds such as naphthalene, anthracene, etc., have extremely small, but detectable, electrical conductivities, which increase exponentially with an increase in temperature according to the equation $\sigma = \sigma_0 \exp(-E/2kT)$, where σ is the specific resistivity, σ_0 is a constant, E is an activation energy generally referred to as the energy gap and T is the absolute temperature. Since it is generally held that the conductivity is electronic rather than ionic, these substances have been termed organic semiconductors[1]. Lyons[2] has pointed out that a correlation exists between the magnitude of the energy gap and a number of molecular properties, such as the molecular ionization energy, the molecular electron affinity, and the excitation energy of the ground-triplet state transition. If it is assumed that the semiconductivity of organic compounds involves the formation of biradicals and hence participation of the triplet state in the conduction process, it becomes evident that the energy gap should be at least equal to the ground-triplet state excitation energy. Of particular interest is the fact that for a number of compounds the energy gap is roughly equal to (generally slightly larger than) the aforementioned excitation energy. Thus, the energy gaps[3] for anthracene, naphthacene, chrysene, pyrene, and anthanthrene are, respectively, 1·95, 1·64, 2·04, 2·06, and 1·58 eV., which are in fair agreement with the ground-triplet excitation energies of 1·82 [4], 1·26 [5], 2·45 [4], 2·08 [3], and 1·32 [3] eV.

We have now found that this relationship apparently also holds true for the heterocyclic compound phenazine. From the dependence on temperature of the resistivity (Fig. 1*a*) of phenazine in the range of 98–143° C., we determined the energy gap as 2·1 eV. This compares favourably with the ground-triplet excitation energy[6] of 1·9 eV. The resistivity was determined in an atmosphere of dry nitrogen on a disk of phenazine which was prepared by compaction

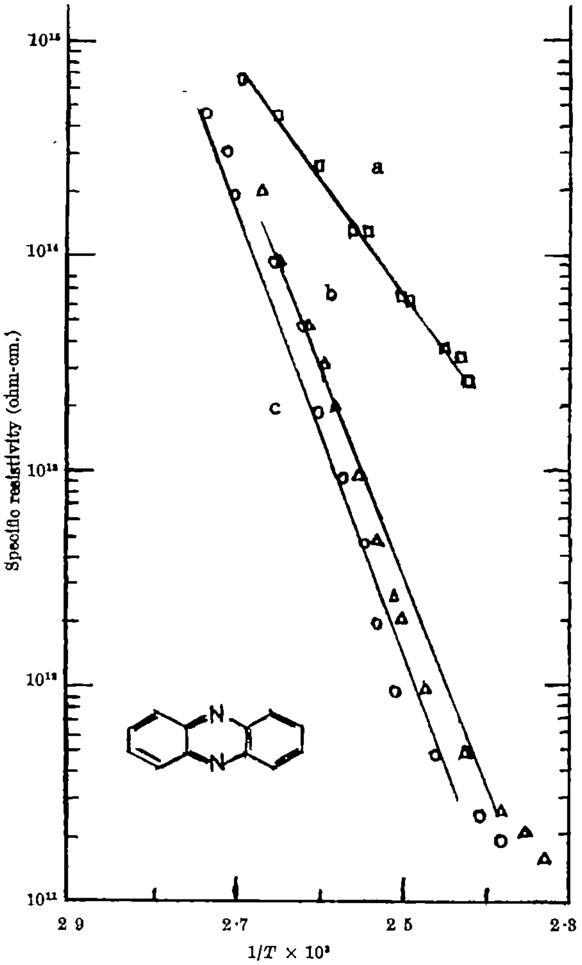

Fig. 1. Specific resistivity of phenazine: *a*, □, zone-refined, 94 and 940 V./cm.; *b*, △, two sublimations, 68 V./cm.; *c*, ○, three sublimations, 67 V./cm.

under high pressure and which was sandwiched between mercury electrodes during the measurements.

There is no *a priori* reason for suspecting that the energy gap obtained from measurements on a compacted polycrystalline material is different from that of a single crystal. Although the possibility of the presence of intergranular resistances in compacted specimens cannot be ruled out, these resistances should not be more serious than those possibly present in evaporated films. Northrop[3] has shown that whereas evaporated films of hydrocarbons have higher specific resistivities than single crystals, both have the same energy gap within experimental error. It is therefore apparent that reliable and theoretically significant energy gaps (albeit not specific resistivities) can be derived from measurements on suitably prepared void-free polycrystalline materials.

The phenazine was purified by chromatography on alumina and subsequent zone-refining, but estimation of the degree of purity was not attempted.

While the process of zone-refining in itself does not constitute evidence of 'hyperpurity', results obtained on conventionally purified phenazine lend support to the assumption that a specimen of high purity was on hand. Figs. 1*b* and 1*c* show, respectively, the resistivity of phenazine which, after chromatography, had been sublimed two and three times in a high vacuum. Both specimens display lower resistivities, particularly at the higher temperatures, and have energy gaps of 3·8–4·0 eV. As it is unlikely that the zone-refined specimen contained a larger number of inert impurities or physical voids than the sublimed specimens, it may be concluded that the higher specific resistivity and lower energy gap obtained in the former are consequences of its greater state of purity.

A detailed account of this work will be published elsewhere. It was supported by the Air Research and Development Command, United States Air Force, under Contract No. *AF* 33(616)–6908 monitored by the Materials Laboratory, Wright Air Development Division, Wright-Patterson Air Force Base, Ohio.

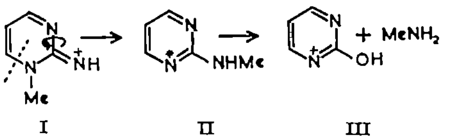
Apparent Migration of N-Methyl Groups in the Pyrimidine Series

The long-standing problem of how methyl groups migrate from nuclear to extra-nuclear nitrogen atoms in heterocyclic compounds has now been decided experimentally in the pyrimidine series.

Methyl iodide reacts[1] with 2-aminopyrimidine to give the hydroiodide of 1,2-dihydro-2-imino-1-methylpyrimidine (I). The free base may be liberated with cold sodium hydroxide, but if the alkaline solution is warmed, rearrangement to 2-methylaminopyrimidine (II) is complete in 10 min.[1,2]. Similar rearrangements are known to occur under both alkaline and acidic conditions in the pyrimidine[3–6], pyridine[7,8], pteridine[9], purine[10], and other[11,12] series.

Two facts of possible significance in connexion with the mechanism of such isomerizations are: (*a*) Rearrangement occurs only when the methyl group and the amino- or imino-group are attached to neighbouring nuclear atoms, and never when they are placed otherwise. (*b*) A nuclear-N-methylated methylaminopyrimidine failed[5] to yield a dimethylaminopyrimidine under conditions where this might reasonably be expected to happen. These facts suggest a hypothesis of hydrolytic ring fission followed by rotation and recyclization. Thus, for example, the rather polarized 1,6-bond in compound (I) would break, allowing rotation about the 2,3-bond and recyclization to the almost aromatically stable compound (II). If this hypothesis is correct, the extra-nuclear nitrogen atom in compound (I) would become a nuclear atom of compound (II).



I II III

To test the hypothesis by this means, 2-chloropyrimidine was heated with ammonia (enriched by nitrogen-15) in ethanol for 2 hr. at 120° C. to give 2-aminopyrimidine labelled in the amino group. This was treated with methyl iodide[1], and the resulting compound (I) (hydroiodide, of melting point 251° C. undepressed by admixture with unlabelled material) was rearranged[1] in hot alkali to 2-methylaminopyrimidine (II). Hydrolysis of the sublimed material (melting point 58° C.; published 59–60° C.) with *N* hydrochloric acid at 160° C. for 6 hr. gave 2-hydroxypyrimidine (III) (melting point 178° C.; published[13] 178–80° C.) and after making the residual solution alkaline, methylamine was isolated using steam-distillation and collected as its picrate (melting point 207° C., undepressed by authentic material). Mass-spectrometric examination of nitrogen samples prepared by burning compound (III) and the methylamine picrate showed a strong nitrogen-15 enrichment in nitrogen from the 2-hydroxypyrimidine, but none in nitrogen from the picrate. The rotation hypothesis for the mechanism of rearrangement was thus valid.

Mr. J. Harper and Mr. B. T. England assisted in the experimental work, and the mass-spectrometric examination was kindly made by Cmdr. J. Mason in the University of New South Wales.

The Sodium Silicate – Ferrous Hydroxide System

We have reported earlier[1] the occurrence of a point of inflexion at *p*H 10·75 on the hydrolysis curve of a 0·01 *M* sodium silicate solution which was attributed to the formation of the trihydroxy – *ortho*silicate ion, but we were unable to detect with certainty a point on this curve corresponding to the final decomposition of this ion to *ortho*silicic acid, $Si(OH)_4$. An investigation of the sodium silicate – ferrous hydroxide system has shed new light on this problem. It is known that controlled oxidation of ferrous hydroxide between *p*H 5·2 and 11·5 yields magnetite[2,3], and it has also been established[4] that silica prevents the formation of magnetite from solution. One could therefore expect a systematic investigation of the sodium silicate – ferrous hydroxide system over a wide *p*H range to assist in clarifying the behaviour of silicic acid.

The experimental procedure involved addition of sodium silicate solutions to 0·005 *M* suspension of precipitated ferrous hydroxide, yielding a final ratio of sodium silicate to ferrous hydroxide of 0·4 : 1 (excess ferrous hydroxide) and 1·5 : 1 (excess silicate) respectively, and subsequent oxidation of two-thirds of the iron present with 0·3 per cent hydrogen peroxide; *p*H of the mixture was varied between 5·1 and 13·8 and the entire operation carried out under a nitrogen atmosphere at 25 ± 0·02° C. Samples were tested for magnetic behaviour and submitted to X-ray analysis using the powder diffraction method.

We found that, below about *p*H 10·7, magnetite is not formed in any appreciable quantities, whereas above this point it is the major product together with some very finely divided α-ferric oxide. On the other hand, an analogous procedure in the absence of silicate ions led us to establish *p*H 5·25 as the lower limit for the formation of magnetite.

It would therefore appear that *p*H 10·7 marks the end of hydrolysis of the dihydroxy – *ortho*silicate ion in 0·002–0·007 *M* sodium silicate solutions:

$$(SiO_2(OH)_2)^{2-} + 2H_2O = Si(OH)_4 + 2OH^-$$

Such freshly formed silicic acid in aqueous solution, being in an active condition[5], will be readily adsorbed by ferrous hydroxide particles and thus prevent the formation of magnetite below *p*H 10·7. This finding can be related to a recent observation[6] that at *p*H 8·5 the formation of magnetite from solution is a solid phase reaction.

We wish to acknowledge a research grant from the National Coal Board and our indebtedness to Prof. H. Lipson and Dr. O. S. Mills for the loan of X-ray equipment.

Reaction of Phosphorylating Agents with 2-Methyl-Δ^2-Oxazoline

Degradation of esteratic enzymes which have been inhibited with di*iso*propyl phosphorofluoridate (DFP) yields serine phosphate[1], although serine itself is completely unreactive to DFP[2]. Kinetic and other evidence[3] suggests participation of the imidazole ring of a histidine moiety in the phosphorylation reaction, although it is not known if the ring is the initial site of phosphorylation or whether it catalyses phosphorylation of the serine. Rydon[4] has postulated that a Δ^2-oxazoline is present in the enzyme which on phosphorylation yields an O-phosphoryl serine residue. This hypothesis was based on the results of Porter *et al.*[5], who showed that 2-aminoethyl phosphate could be isolated from the reaction of 2-methyl-Δ^2-oxazoline (I) and DFP in aqueous solution. Since acylating agents[6] react with I to give stable N-acyl derivatives, and since 2-aminoethyl phosphate was isolated by Porter *et al.* following acid hydrolysis of the product (conditions under which N → O migration of phosphoryl groups is known to occur[7]) the reaction of I with phosphorylating agents was further examined.

An aqueous solution of I buffered at *p*H 8·2 with sodium bicarbonate reacted with an equimolar amount of di*iso*propyl phosphorochloridate (DClP) to give, after stirring for 24 hr. at room temperature, di*iso*propyl 2-acetoxyethylphosphoramidate in 51 per cent yield. Under these conditions no phosphorylated products were obtained with DFP. When the experiment was repeated with a three-fold excess of DFP under the conditions employed by Porter *et al.* (*p*H 7·8, 37°, 4 days with *iso*propanol added to homogenize the system[8]) two products were isolated from a chloroform extract by chromatography on Woelm IV neutral alumina followed by quantitative electrophoretic separation. They were identified as 2-aminoethyl di*iso*propyl phosphate (0·07 per cent) and 2-acetamidoethyl di*iso*propyl phosphate (0·08 per cent) by means of their infra-red spectra and their behaviour on paper chromatography and electrophoresis. Using these latter conditions the reaction of DClP with I gave di*iso*propyl 2-acetoxyethylphosphoramidate (20 per cent) and di*iso*propyl 2-hydroxyethylphosphoramidate (0·4 per cent). It was found that I was almost completely converted to N-acetyl ethanolamine (II) after 3½ days in water/*iso*propanol buffered at *p*H 7·8 with sodium bicarbonate. It therefore seemed feasible that the O-phosphoryl products obtained from an aqueous solution of I and DFP could have resulted from the side reaction of II with DFP. Experiments did in fact show that, under identical conditions, II reacted with DFP giving 2-acetamidoethyl di*iso*propyl phosphate (0·35 per cent).

These results indicate that the O-phosphoryl derivatives obtained from aqueous solutions of I and DFP are not formed by N → O migration during the isolation procedure. However, it is difficult to explain why DFP should react with I to give an O-phosphoryl derivative although DClP yields a stable N-phosphoryl derivative as would be expected from the analogous reaction of acylating agents. The reaction of II with DFP giving O-phosphoryl compounds may provide an explanation of the anomaly. These facts should be borne in mind while considering the hypothesis of serine being present in the active site of esteratic enzymes as an oxazoline ring.

Enhancement of Atomic Absorption in the Flame by Organic Solvents

ATOMIC absorption methods for the determination of many cations have attracted much attention[1,2] lately. The techniques so far described usually involve the use of a flame for the production of a population of atoms, but the method is of wider application than emission flame photometry and seems to be free of some, though by no means all, of the inter-element effects that bedevil emission methods. The sensitivities obtained are high, especially for certain elements, for example, magnesium, zinc, but for others, particularly in specialized applications, for example, calcium in biological materials, a higher performance is desirable, and it is therefore of interest to look for ways of enhancing sensitivity. We have found that an improvement of 100–1,000 per cent (depending on the element under assay) can frequently be achieved if the test solutions are made to contain a high (⋗ 50 per cent v/v) concentration of an organic solvent such as propanol or acetone.

Table 1 shows the effect of a variety of alcohols at several concentrations on the atomic absorption resulting from spraying a standard magnesium chloride solution containing 2·4 p.p.m. magnesium. It will be observed that the readings increase with increasing amounts of alcohol, but that the initial small additions have a proportionally greater effect. This initial effect is more marked as the chain-length increases.

Table 1

Organic solvent (per cent)	Organic solvent				
	MeOH	EtOH	PrOH	BuOH	AmOH
0	0·187	0·181	0·185	0 180	0·180
15			0·332	(8 per cent) 0·348	(2 per cent) 0·270
33	0·326	0 389	0·447		
50	0·390	0·448	0·447		
66	0·450	0·502	0·447		

Flame coal gas, 15 lb./sq. in. in air from cylinder. Slit width, 0 2 mm. Line, 2852 Å. 2·4 p.p.m. magnesium ions. Each series sprayed three times. Range of reading ± 3 per cent.

Similar results are found with other elements, and Table 2 shows the enhancement we have found, for the elements listed, in 50 per cent *iso*propanol solution. We have found this a convenient solvent to use because the enhancement reaches a plateau at this concentration of propanol or *iso*propanol, hence there is no point in exceeding it, but the flame stability was rather better with the branched-chain alcohol.

Table 2

Element sought	Line	Atomic absorption in 50 per cent *iso*propanol is enhanced by a factor of (approximately)
Ni	3414	2
Cs	8521	1·3
Ag	3281	2
Ca	4226	3
Fe	2483	8–10
Zn	2138	2

The reason for the increased sensitivity is not clear. It is not due entirely to surface tension and viscosity changes, for experiment shows that neither the spray-rate nor the spray efficiency (that is, the fraction of the spray going forward into the flame) changes by anything like the amount required to account for the enhancement, while the addition of 'Aerosol *T*', a proprietary surface-active agent, had no effect. Moreover, the effect is quantitatively different from one element to another.

It is well known that organic solvents similarly enhance emission in the flame, and this has been attributed to increases in flame temperature, which is, of course, much more important in emission than in absorption. There is also the possibility that the production of free atoms is favoured by the change in flame chemistry brought about by the introduction of the organic solvent. This would be effective both in absorption and emission. We have therefore carried out the following experiment. The standard apparatus used for this work (Hilger *H*.700 spectrophotometer with *H*.909 atomic absorption attachment) was modified so that the burner could be fed with the mixed aerosol from two atomizers. Then: (1) an aqueous solution was sprayed; (2) a solution in 50 per cent propanol was sprayed; (3) an aqueous solution was sprayed from one atomizer and propanol from the other. Conditions were adjusted so that the amounts of test element, water, and alcohol actually entering the flame were the same in (2) and (3). The expected enhancement was found in (2) but not in (3). Since the amounts of alcohol and water entering the flame were similar in (2) and (3) it is reasonable to suppose that chemical and temperature conditions were similar. Clearly the explanation of the enhancement must be sought elsewhere. It seems possible that it is to be found in some change in the transient conditions that exist as the solvent in the droplets evaporates in the flame; but further elucidation is required. In the meantime, there is no doubt that a useful increase in sensitivity can be achieved if it is possible to work with organic solvents similar to those described. Other classes of compound show similar effects, for example, hydrocarbons, but are not recommended as they tend to cause instability of the flame.

One of us (J. E. S.) is indebted to the Leverhulme Foundation for a research fellowship.

Isolation of L-Galactose-6-sulphate from a Seaweed Polysaccharide

Sulphated polysaccharides occur widely as major components of many seaweeds[1]. Until now, however, locating the sulphate hemi-ester groups in the polysaccharide structure has rested upon evidence from methylation data[2,3], supported in some cases by infra-red spectroscopy[4,5]. Here we report the application of the method of partial acidic hydrolysis to determine the position of sulphate residues in porphyran, the mucilage of the red seaweed *Porphyra umbilicalis*.

Our earlier work[6,7] has shown that porphyran contains residues of D-galactose, L-galactose, 6-O-methyl-L-galactose, 3,6-anhydro-L-galactose and ester sulphate respectively in the molar ratios 100 : 110 : 118 : 73 : 140. A similar polysaccharide has been isolated from *Porphyra capensis*[8]. The fact that the 3,6-anhydrogalactosidic linkages in these polysaccharides are very sensitive to hydrolysis in acid solutions[9,10] has prompted us to seek conditions under which glycosidic hydrolysis would proceed without the occurrence of any other changes in the polysaccharide structure. Degradation of the polysaccharide with 0·58 *N* sulphuric acid at 50 ± 1° C. for 10 hr. appeared to fulfil this condition. After this treatment, and neutralization with barium carbonate, the product was separated into fractions containing relatively high molecular weight and relatively low molecular weight substances. The fraction containing relatively high molecular weight products was isolated by precipitation from 90 per cent ethanol and subjected to further acid hydrolysis. Comparison of the rates of glycosidic and ester sulphate hydrolysis (Fig. 1) showed that after 5 hr., monosaccharide sulphates would be present in the hydrolysate, with very little contaminating oligosaccharides. It was calculated that about 27 per cent of the monosaccharide sulphate combined in the original polysaccharide could be recovered in this way. The sugar sulphate fraction was accordingly isolated from the hydrolysate by a combination of chromatography with thick paper[11], chromatography on a type of charcoal sufficiently active to retain sugar sulphates[12] and electrophoresis using a thick filter paper support and a volatile buffer[13]. The product, which was obtained as a syrup, was assigned the structure of L-galactose-6-sulphate on the following evidence: Equimolar quantities of galactose and sulphate were liberated on acid hydrolysis. The substance was shown to be a monosaccharide derivative by the method of Peat, Whelan and Roberts[14], and it moved as a single spot parallel to authentic D-galactose-6-sulphate on paper chromatography in a variety of solvent systems[11,15] and on paper electrophoresis. When treated with unbuffered sodium metaperiodate solution, 3·5 moles of oxidant[16] were consumed fairly rapidly, with no liberation of formaldehyde. This is identical with the behaviour of authentic D-galactose-6-sulphate[17]. Finally, the specific optical rotation $[(\alpha)_D = -47°$, sodium salt in water $c = 0{\cdot}15]$ was equal in magnitude, but opposite in sign, to the value for an authentic specimen of D-galactose-6-sulphate[11].

The fact that this 6-sulphate has been isolated as a hydrolysis product of porphyran cannot be taken as proof of its presence as a component of the original polysaccharide, unless it can be shown that sulphate ester migration has not occurred during hydrolysis. Although acyl migration of this type is well estab-

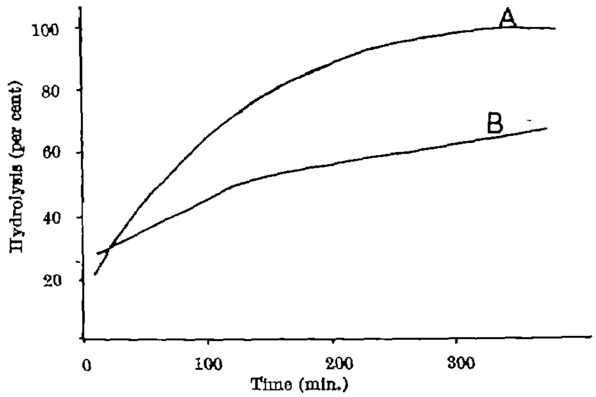

Fig. 1. Hydrolysis of oligosaccharide mixture with 0·24 *N* hydrochloric acid at 100° C. Increase in reducing power was estimated by the method of Somogyi (ref. 18) and sulphate liberation by the method of Jones and Letham (ref. 19)
A, glycosidic hydrolysis; *B*, sulphate ester hydrolysis

lished, for example, in the case of sugar acetates and sugar phosphates, it is considered unlikely here, in view of recent experiments in this laboratory with synthetic sugar sulphates. These experiments[20] have shown that when certain typical sugar sulphates (galactose-6-sulphate, galactose-4-sulphate, glucose-6-sulphate, and glucose-3-sulphate) are heated in dilute acid solution, the only reaction which can be detected by paper chromatography is the liberation of the parent sugar.

The analytical figures quoted above show that the number of sulphate ester groups present in the polysaccharide exceeds the number of L-galactose residues, and hence not all the sulphate in porphyran can occur as L-galactose-6-sulphate. Since only L-galactose-6-sulphate was isolated, it would seem that the other ester sulphates present are more acid labile. The inflexion in the curve representing the rate of sulphate release (Fig. 1) supports this view, and also suggests that more than half the total ester sulphate is liberated in the second phase of the hydrolysis at a slow rate, that is, is presumably released from the more acid-stable L-galactose 6-sulphate residues.

The conclusion is reached that L-galactose-6-sulphate is probably a major unit in the structure of porphyran. This recalls the speculations of Jones and Peat[21], to which attention has recently been directed by Hirst[1]. Jones and Peat pointed out that a simple intramolecular oxidation-reduction reaction would convert D-galactose-1-sulphate into L-galactose-6-sulphate, which could then be converted by base-catalysed sulphate elimination into 3,6-anhydro-L-galactose. Hirst has added that it is also possible to postulate a mechanism of this type for the biosynthesis of L-guluronic acid in algin.

We thank Prof. Stanley Peat for his interest and encouragement, and also Mr. T. P. Williams for the D-galactose-6-sulphate used as a reference compound.

BIOCHEMISTRY

Localization of Arginase in Rabbit Skin

ROGERS[1] has reported the induction of arginase in rabbit epithelium by the Shope papilloma virus. This conclusion was based on his findings of: (*a*) an increased uptake of arginine in papilloma tissue as compared to normal and hyperplastic whole skin; (*b*) the presence of appreciable quantities of arginase activity in papilloma tissue as compared to only trace amounts in extracts of normal skin.

We would like to propose an alternate interpretation of these findings on the basis of other data of arginase activity found in isolated tissues of the skin, interpreted in the light of the basic anatomy of the skin.

It is important to remember that the skin, exclusive of subcutaneous tissues, consists mainly of epithelium and connective tissue. The epithelial tissues, (epidermis, pilosebaceous follicles, and eccrine sweat units) constitute only a relatively small fraction of whole skin, the greater bulk being connective tissue (corium). Although arginase activity is detectable in whole skin[2,3], its localization is confined to the epidermis[4-7] and epidermal appendages[8]. It is not present in the corium, at least in amounts measurable by usual methods. In pathological conditions of human skin where the epidermis is both hyperplastic and hyperkeratotic (for example, psoriasis, verruca vulgaris, plantar callus), arginase activity in the epidermis is markedly increased[5,6]. In basal cell carcinoma, however, where the epidermis is hyperplastic but not hyperkeratotic, arginase activity has been found to be normal[6]. Activity of the enzyme in skin, therefore, seems to parallel the degree of epidermal keratinization.

The present work was performed to verify that the pattern of arginase activity in rabbit skin is similar to that found in the skin of man and other animals.

The trunk skin of a normal New Zealand albino rabbit was removed and cut into half-inch strips. The strips of skin were stretched tightly on a board with dissecting needles and the epidermis scraped from the underlying corium with a scalpel[9]. The removed epidermis contained no corium, although it was visibly contaminated with hair stubble. This material was lyophilized, defatted with ether, and ground in a Wiley mill fitted with a 60-mesh screen. Only 20 mgm. of dry, powdered epidermal material was obtained from the greater portion of the trunk skin. A specimen of whole skin (containing epidermis, epidermal appendages, and corium) was powdered in similar fashion, yielding several grams of material.

Arginase activity of each tissue specimen was microassayed as described previously[8]. In this assay approximately 1-mgm. samples of epidermis, weighed on a Kahn electrobalance, were used; 5-mgm. samples of whole skin were used. The enzyme was activated by incubating the tissue with 0·2 ml. of 0·05 M manganese chloride at 50° C. for 1 hr. Immediately thereafter 0·05 ml. of substrate, 1·7 M arginine (*p*H 9·5), was added and the suspension incubated for 1 hr. at 37° C. The reaction was stopped by the addition of 0·05 ml. of 1·2 M sulphuric acid. The urea formed was enzymatically hydrolysed by urease at *p*H 5·0; the ammonia was liberated from solution with saturated potassium carbonate and diffused to acid in the centre well of a Conway dish. The ammonia was Nesslerized and quantitated with a Beckman *DU* spectrophotometer at a wave-length of 420 mμ. The results are shown in Table 1.

Table 1. ARGINASE ACTIVITY IN RABBIT SKIN

Experiment No.*	Wt. sample (mgm.)	γ Urea nitrogen found after enzymatic reactions			Activity†
		Complete system	Boiled tissue system	Corrected	
Epidermis					
1	0·854	53 4	14·7	38·7	4,580
2	0 982	50 1	13 6	36 5	3,715
Whole skin					
3	5 3	84 5	41 7	42 8	790

* The results of each experiment are averaged values from two or more determinations.

† Expressed as milligrams urea nitrogen per 100 gm. dry, defatted tissue resulting from hydrolysis of arginine on incubation for 1 hr. at 37° C.

The values of arginase activity obtained indicate that the enzyme in rabbit skin is largely localized in the epidermis, and that the activity in whole skin is due to the epidermis and epidermal appendages thereof. Localization of arginase in rabbit skin is thus similar to that in the skin of man. In view of the fact that arginase activity increases in hyperplastic, hyperkeratotic human epidermis, it seems reasonable to expect a similar increase in papillomas of rabbit skin, which are also characterized by epidermal hyperplasia and hyperkeratosis. The conclusion that the Shope virus induces arginase in rabbit epidermis, therefore, seems unwarranted.

The significance of arginase in normal epidermis, as well as its elevated activity in hyperkeratotic epidermis, is nevertheless unexplained. Examination of normal human epidermis for the enzymes of the Krebs–Henseleit urea cycle has revealed that, of these enzymes, only arginase is present[10]. Thus, the role of arginase in epidermis does not seem to be the same as that classically ascribed to it in liver.

Multi-stranded Deoxyribonucleic Acid as determined by X-Irradiation

IT has been widely assumed that DNA from all sources is two-stranded. However, much of the available data are consistent with more complex structures. We wish to emphasize that only those methods which actually count the number of strands per molecule are valid for examining this question. Enzyme kinetics is such a method, and has been used to show that calf thymus DNA is approximately two-stranded[1]. We have recently carried out a detailed investigation[2] of deoxyribonuclease II kinetics, using as substrates DNA samples from a variety of sources. Two classes of DNA molecules were found : namely, unitary molecules (two-stranded) and biunial molecules (four-stranded). The existence of four-stranded molecules, or pairs of double helices, has been confirmed by electron microscopy[3]. New evidence is presented here in support of these findings.

The decay in molecular weight brought about by X-irradiation has been examined as a function of X-ray dose. The following equation, which has been derived elsewhere[2], was used to express the results :

$$\frac{1-R}{R} = m(\Pi B)p^n = m(\Pi B)(kD)^n = [m(\Pi B)k^n](D)^n$$

where R is the ratio of the weight-average molecular weight after a given dose to the initial weight-average molecular weight ; $(1-R)/R$ is the number of molecular cleavages caused by the given dose ; m is the number of internucleotide bonds per polynucleotide strand ; ΠB is a function which takes into account the possibility that molecular cleavage can occur even though the single-chain scissions are not directly opposite one another ; p is the cumulative probability that a given bond will be cleaved (in the present communication, p is proportional to X-ray dose, D) ; n is the number of polynucleotide strands per molecule. When log $[(1-R)/R]$ is plotted against log D, as in Fig. 1, the slope of the resulting line is n.

This equation was derived for random degradation ; it has been shown[4] that use of the equation when degradation is non-random leads to apparent values of n which are too low. The question is whether or not X-rays produce random degradation. It has been shown[4] that the X-ray degradation of DNA in solution is brought about indirectly by the free radicals formed in water. These occur in clusters having an initial diameter of about 20 Å. and containing about five pairs of radicals. Thus, any clusters formed in the immediate vicinity of a molecule could produce several simultaneous strand cleavages in the same region. A certain degree of non-randomness,

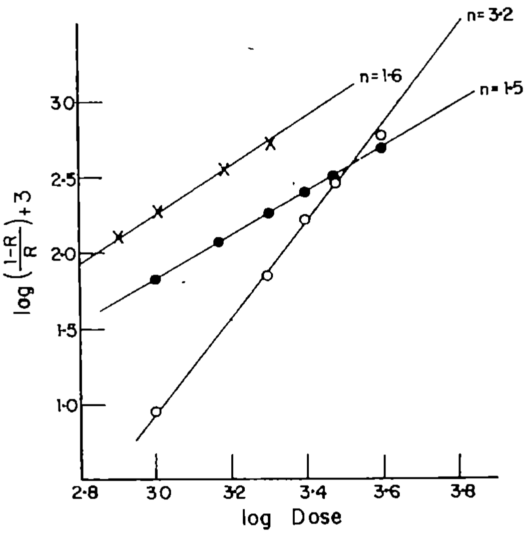

Fig. 1. Plot of log[molecular cleavages] versus log[dose], where the dose is given in rads. The slopes of the lines give values of n of 1 5, 1·6 and 3 2 for calf thymus, sea urchin sperm and *Pneumococcus* DNA respectively. The DNA samples studied have been designated as *OS*, *TS*-I and *LC*-II, respectively ; their initial molecular weights were 1·9, 2 2 and 1·6 million. The isolation and disaggregation of these samples are described elsewhere (ref. 5)

resulting in low values for the number of strands per molecule, is therefore to be expected.

Molecular weights were determined by light scattering. X-irradiation was carried out with a 180-keV. source, using a copper–aluminium filter, at a rate of 80 rads/min. The concentration of DNA was 0·1 mgm./ml., in 0·002 *M* sodium acetate. Solutions were made 0·2 *M* in sodium acetate immediately after irradiation and shaken with chloroform–octanol[5] before making light-scattering measurements, which were performed within 1–2 hr. Apparently no after-effects occurred under these conditions, since there was no change in molecular weight with time (up to about 24 hr.).

Fig. 1 shows that the number of strands (n) per molecule of DNA from calf thymus, sea urchin sperm and *Pneumococcus* appears to be 1·5, 1·6 and 3·2 respectively. For calf thymus and *Pneumococcus* DNA, n was previously found[2] by deoxyribonuclease II kinetics to be 1·7 and 4·2, ± 0·3, respectively, and sea urchin sperm DNA was predicted to be two-stranded[6]. The somewhat lower values obtained in the present investigation must be attributed to non-random attacks, and thus constitute minimum estimates; the previous work was shown to involve only random enzymatic attacks. The salient point is that n for *Pneumococcus* DNA is twice that for the other samples, all of which were undenatured and had the physical properties of stiff chains or double helices. Thus, the results of the present work support the conclusions reached earlier on the basis of enzyme kinetics and other evidence, that DNA molecules from non-proliferating sources are double helices, whereas molecules from proliferating sources consist of linked pairs of double helices.

This investigation was supported in part by funds from the National Cancer Institute, National Institutes of Health, Public Health Service (grant *CY*-3190), from the Atomic Energy Commission (Contract *AT*(30–1)–910), and from the American Cancer Society.

Interference in the Diphenylamine Procedure for estimating Deoxyribonucleic Acid

THE importance of deoxyribonucleic acid (DNA) in the control of cellular propagation is now well established. The amount in each somatic cell is constant for a particular species, deviations occurring with multinucleate cells or with polyploidy. With certain exceptions the DNA content of a tissue sample is directly related to the number of cells in that sample. This constancy has led to the widespread use of DNA as a standard of reference in biochemical investigations.

A general procedure for estimating DNA in tissue samples is the diphenylamine reaction; the variables of this reaction have been reviewed[1]. In most normal tissues this reaction satisfies the accepted criteria for a reliable assay method. The usual procedure is to extract the tissue with hot trichloracetic acid[2] and then to boil the extract with diphenylamine reagent for 5–15 min.; the resulting purple-blue colour is measured at 595 or 600 mμ. The extinction produced on boiling pure DNA with diphenylamine reagent increases rapidly with the time of boiling up to about 5 min., and then only slowly between 5 and 15 min.

Under certain conditions, the diphenylamine reaction is open to gross interference[1]; for example, the vivid green coloration produced by some plant extracts[3]. Dische[1] has proposed a multi-chromatic method for correcting such interference when the interfering chromagen has a sufficiently different spectrum from that of the colour produced by DNA. In general, however, such interferences are only specifically looked for when the visual appearance of the final diphenylamine colour is very different from the purple-blue of the DNA colour. The fact that interference may be considerable without appreciably affecting the visual appearance of the final colour, and the variation of such interference with time of boiling, do not appear to be sufficiently widely known.

Hot trichloracetic acid extraction of many tissues (and blood) solubilizes components other than DNA; these produce similar bluish colorations under the conditions of the diphenylamine reaction[4]. It is probable that these components are largely mucosaccharide in character[5]. After boiling with diphenylamine, the interfering chromagens have a main absorption maximum at 530 mμ and a smaller maximum at approximately 660 mμ (the exact position depends not only on the tissue but also on the time of boiling); these interfering colours develop more slowly on boiling with diphenylamine than is the case with DNA (ref. 4 and unpublished work). With many normal rat tissues, the amount of interference present is insufficient to produce appreciable error in estimations of DNA, providing the time of boiling is not longer than 10 min.; the extent of the interference increases rapidly with times of boiling in excess of 15 min.

With certain other tissues, however, there is considerably more interfering substance present, which produces a significant inaccuracy in estimations of DNA even when the time of boiling is 10 min. Fig. 1 shows the absorption spectra obtained by boiling a trichloracetic acid extract of involuting rat mammary gland with diphenylamine reagent for 4, 10 and 30 min. It can be seen that as the time of boiling is increased, the 530 mμ peak becomes more prominent; at the same time the extinction at 600 mμ also increases, unlike the behaviour of DNA itself. To assay DNA with any accuracy in such a tissue the time of boiling should not exceed 5 min. There is appreciably less interference present in mammary tissue at other stages in the lactation-cycle; the increased amount in involution appears to be largely the result of the accumulation of milk in the gland at this stage. The visual appearance of the final colour,

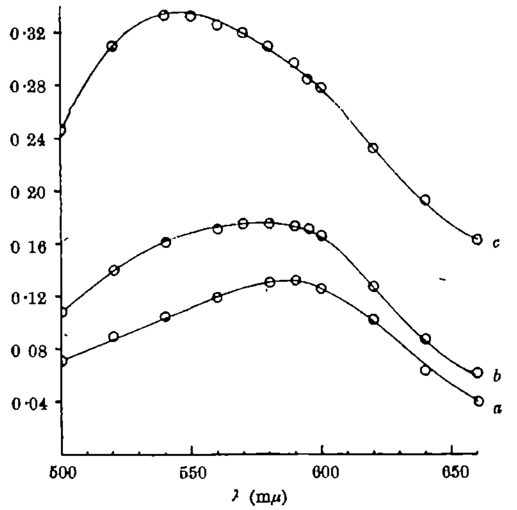

Fig. 1. Absorption spectra obtained after boiling trichloracetic acid extracts of rat mammary gland with diphenylamine reagent for varying times. Curves *a*, *b* and *c* obtained after boiling for 4, 10 and 30 min. respectively. The animal was in the first day of mammary involution, that is, the pups had been removed 24 hr. previously, at which time the rat had been in full lactation

even when considerable interference is present (as shown by a high 530-mμ peak), is not noticeably different from the colour produced by pure DNA.

Normal blood serum contains substances which interfere in the diphenylamine reaction for DNA by producing a peak at 530 mμ on boiling for long periods[3,7]. The concentration is raised in certain disease states, for example, inflammatory rheumatoid arthritis[4,6] and certain types of malignancy[7].

It is the purpose of this communication to point out that when the diphenylamine reaction is to be used for estimating DNA in tissues other than those already characterized (see refs. 1 and 2), or in which the diphenylamine reaction has been found to give results in agreement with alternative methods of assay, the variation in the absorption spectrum with time of boiling should be investigated to check the magnitude of possible interference with the time of boiling to be used. From the work on mammary gland and serum, it would appear that interference in the diphenylamine reaction can vary with the physiological status of the animal; care should therefore be exercised when using the diphenylamine reaction to compare DNA values under different physiological states when the concentration of interfering substance (mucosaccharide ?) may vary considerably.

I am grateful to Prof. C. Rimington and Dr. A. L. Greenbaum for their helpful comments.

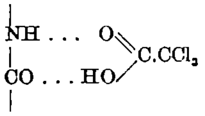
Binding of Trichloroacetic Acid by Protein

TRICHLOROACETIC acid (TCA) is widely used as a protein coagulant in the preparation of protein-free sera; but there is little information concerning its mode of action. Rowland[1] has shown that the complete separation of protein from milk requires a concentration of 8 per cent TCA at room temperature. We have determined the amounts of TCA bound by milk proteins at this concentration (Table 1).

Table 1. BINDING OF TRICHLOROACETIC ACID BY MILK PROTEINS

Protein	No. of samples examined	Trichloroacetic acid bound		
		Range	Average	
		gm. TCA/ 100 gm. protein	gm TCA/ 100 gm. protein	moles TCA/ 10^5 gm. protein
Casein	8	39–47	42	257
β-Lactoglobulin	2	92–102	97	594
Total whey protein	4	70–83	77	—

In 10^5 gm of whole casein[2] and β-lactoglobulin[2] there are 107 and 120 cationic side-chain groups respectively. If all these were available for binding TCA there remains a considerable number of sites at which the acid must be bound to account for the figures quoted above. We consider that these sites are provided by peptide bonds, the TCA being held in the following manner:



The elimination of bound water and its replacement by the strongly non-polar $Cl_3C.C$— radical destroys the solubility of the protein in water and tends to render it soluble in non-polar solvents. TCA–protein complexes dissolve to a varying degree in absolute alcohol or acetone, and the soluble fraction can be transferred to benzene and chloroform[3]. The alcohol-solubility of the TCA–protein complex varies over a narrow range for any particular undenatured protein and is related to the degree of binding of TCA by the protein (Table 2).

Table 2. SOLUBILITY IN ABSOLUTE ALCOHOL OF THE VARIOUS MILK PROTEINS AFTER PRECIPITATION WITH TCA

Protein	No. of samples examined	Final concentration of TCA	Solubility in alcohol	
			Range (per cent)	Average (per cent)
Casein	14	0·5 *M*	2 87– 5·38	3·95
β-Lactoglobulin	4	,,	69 0 –75·0	72·0
α-Lactalbumin	2	,,	36 0 –41·0	39·0
Globulins	1	,,	10·0	10 0
Proteose	1	,,	9 0	9·0

In the case of TCA–casein the alcohol-solubility is unaffected by particle size and the fraction dissolved contains all the known casein fractions in approximately the same ratio as they are present in native casein. A reduction in the number of TCA binding sites reduces the alcohol-solubility of the TCA–protein, and we have used this index of solubility to follow protein denaturation, protein–protein interaction and protein–sugar interaction in both model systems and in heated milk.

Diglyceride Kinase and Phosphatidic Acid Phosphatase in Erythrocyte Membranes

WE have recently provided evidence that in the avian salt gland sodium is pumped by a mechanism which we have termed the phosphatidic acid-cycle[1,2]. In this mechanism phosphatidate functions as a sodium ion carrier in the membrane; the phosphatidic acid-cycle consists of two enzymes—diglyceride kinase, which forms phosphatidate from diglyceride and adenosine triphosphate, and phosphatidic acid phosphatase, which hydrolyses phosphatidate to yield diglyceride and orthophosphate. If the phosphatidic acid-cycle is a general mechanism for active sodium transport one would expect to find the enzymes of this cycle in all membranes which actively pump sodium. This preliminary report is concerned with the presence of these enzymes in erythrocyte membranes.

Membranes were prepared from hæmolysed human erythrocytes[3] and were incubated with an adenosine triphosphate-γ-phosphorus-32 generating system[4]. Under these conditions, phosphatidic acid became labelled with phosphorus-32; no other radioactive phosphatides were seen on chromatograms of the total lipid extracts. The radioactivity found in the phosphatidic acid spot on the chromatograms accounted for 80–100 per cent (uncorrected for breakdown of phosphatidic acid during chromatography) of the total radioactivity in the lipid extract (Table 1). These results indicate that phosphatidic acid is formed from adenosine triphosphate in the erythrocyte membrane.

Addition of diolein to the incubation system markedly increased the formation of phosphatidic acid; this indicates the presence of diglyceride kinase in the erythrocyte membrane. In the presence of added diglyceride the diglyceride kinase was stimulated by potassium, the optimum potassium concentration being 60–80 m.equiv./l. Sodium was on average about one-fifth as effective as potassium. No stimulation by sodium was observed in the presence of optimum concentrations of potassium.

Table 1. DIGLYCERIDE KINASE IN ERYTHROCYTE MEMBRANES

Exp. No.	Cation concentration (m equiv./l)		Diolein added	Radioactivity in phosphatides (counts/min./mgm. dry weight of ghosts)	
	Sodium	Potassium		Total extract	Phosphatidic acid
1	60	30	0	375	298
			10 μl.	1,420	1,400
2	0	0	10 μl.	667	
	0	20	10 μl.	820	
	0	40	10 μl.	951	
	0	80	10 μl.	1,180	
	0	120	10 μl.	1,180	
	16 5	0	10 μl.	835	
	31	0	10 μl.	920	
	62	0	10 μl.	945	
	93	0	10 μl.	910	

1 2 mgm. (dry weight) of erythrocyte ghosts were incubated in 0 25 ml. of incubation medium for 1 hr. at 37° C. After incubation the radioactivity of the total lipid extract and phosphatidic acid were determined as described previously (ref. 4). The incubation medium consisted of the following (expressed as final concentrations): imidazole–histidine–*tris* buffer, *p*H 7·1 (0·025 *M*), magnesium sulphate (0 002 *M*), *tris* carbamyl phosphate-^{32}P (0 0035 *M*), dialysed carbamate kinase from *S. faecalis* (0 3 units/ml.), *tris* fluoride (0 01 *M*), *tris* adenosine diphosphate (0·0004 *M*). The specific activity of the carbamyl phosphate-^{32}P was 2 5 × 10^6 counts/min./μmole.

Incubation of erythrocyte membranes with phosphatidic acid yielded orthophosphate (Table 2), indicating the presence of phosphatidic acid phosphatase. Two types of phosphatase activity were present in the membrane, one of which was independent of the presence of magnesium and one which was dependent on the presence of magnesium. The optimum concentration of magnesium was about 1 m.equiv./l. Sodium ions inhibited somewhat the magnesium-independent phosphatase but stimulated the magnesium-dependent phosphatase. In some experiments the magnesium effect was seen only in the presence of sodium, but in others a partial stimulation by magnesium occurred in the absence of sodium. Preliminary experiments indicate that the dependence of the magnesium effect on the presence of sodium develops with ageing of the preparation.

Table 2. PHOSPHATIDIC ACID PHOSPHATASE IN ERYTHROCYTE MEMBRANES

Exp. No.	Cations added*	Total phosphatidic acid phosphatase (mμmoles of ortho-P formed per mgm. dry wt. of ghosts)	Mg^{++}-dependent phosphatidic acid phosphatase (mμmoles of ortho-P formed per mgm. dry weight of ghosts)
1	None	5·1	
	Mg^{++}	5·1	0
	Na^+	3·1	
	$Na^+ + Mg^{++}$	9·1	6·0
	Li^+	4 9	
	$Li^+ + Mg^{++}$	9·2	4 3
	NH_4^+	4·1	
	$NH_4^+ + Mg^{++}$	6 1	2 0
	K^+	5·1	
	$K^+ + Mg^{++}$	6·2	1 1
	Cs^+	5 3	
	$Cs^+ + Mg^{++}$	5 2	0
2	None	4 6	
	Mg^{++}	9 1	4 5
	Na^+	4·0	
	$Na^+ + Mg^{++}$	13 2	9·2

* The final concentration of magnesium was 0·8 m.equiv./l. and the final concentration of each of the monovalent cations listed was 155 m.equiv./l.

5·5 mgm. (dry weight) of erythrocyte ghosts were incubated in 1·0 ml of incubation medium at 37° C. for 1 hr. The incubation medium contained the following (expressed as final concentration): *tris* dioleyl phosphatidate-^{32}P (0·002 *M* in experiment 1 and 0·003 *M* in experiment 2) and imidazole–histidine–*tris* buffer, *p*H 7 1 (0 03 *M*). The *tris* phosphatidate ranged in specific activity from about 10 counts/min./mμmole to about 120 counts/min./mμmole After incubation 0·05 ml of 10 per cent crystalline bovine albumin was added to the incubation vessel, followed by 1 ml. of 10 per cent trichloracetic acid. After centrifugation the trichloracetic acid extract was washed three times with wet ether, and a 1-ml. aliquot of aqueous phase was dried on a planchet and counted. An incubation with boiled ghosts was used as the blank. All values are averages of triplicate incubations

The combined actions of diglyceride kinase and phosphatidic acid phosphatase results not only in the synthesis and breakdown of phosphatidic acid but also in adenosine triphosphatase activity. Adenosine triphosphatase activity has been shown to be closely related to the action of the sodium–potassium pumps in both nerve[5] and erythrocyte[3] membranes. This adenosine triphosphatase is dependent on the presence of both sodium and potassium and also requires magnesium. Since the combined activities of the two enzymes of the phosphatidic acid-cycle require sodium, potassium and magnesium, it is possible that this cycle may be identical with the adenosine triphosphatase activity related to the sodium–potassium pumps.

Lecithin-splitting Enzyme of *Vibrio* El Tor

IT was known that *Vibrio cholerae* and *Vibrio* El Tor excrete a lecithin-splitting enzyme in their culture medium[1-3], but the nature of this enzyme was not properly ascertained. The present communication is concerned with the characterization of the enzyme excreted by *Vibrio* El Tor with special reference to some of its important properties. The enzyme was isolated from the culture filtrate of the organism, which was grown aerobically in surface cultures using peptone–water medium for 48 hr. The culture filtrate was fractionated by ammonium sulphate and the precipitate obtained between 50–75 per cent saturation contained all the enzyme activity. This was dissolved in 0·01 *M* phosphate buffer and after dialysis against the same buffer was kept frozen at − 15° C. for about four weeks, up to which time no loss of enzyme activity has been noticed. Addition of glycerol is not necessary for its storage.

The enzyme has been found to attack only lysolecithin molecules liberating acid-soluble phosphorus and acid-labile choline compounds without any liberation of free choline and is inactive towards purified lecithin. The incubations were performed in 10-ml. stoppered centrifuge tubes into which the requisite amount of lipid substrate in chloroform solution (usually 0·75 μmole) was added. The solvent was removed *in vacuo* at about 40° C. and the lipid was then mixed up in buffer solution (50 μmoles barbital buffer of *p*H 8·0, which has been found to be its optimum *p*H). The enzyme equivalent to approximately 0·15 mgm. protein was then added and the total volume of the incubation mixture was kept 1 ml. The incubations were made at 37° C. for 1 hr., after which the reaction was stopped by the addition of trichloracetic acid solution to a final concentration of 5 per cent in the presence of bovine serum albumin (5 mgm. per flask). This was centrifuged, the centrifugate was extracted once with three volumes of a mixture of chloroform and *iso*butanol (2 : 1, v/v) and was again centrifuged. The aqueous portion which was separated was analysed for the reaction products. It has been noted that there is a decrease in the fatty acyl ester group and simultaneous increase in acid-soluble phosphorus, and these are in quantitative proportion with the release of acid-labile choline compound. This choline compound has been identified as glycerophosphoryl–choline with the help of paper chromatography according to the method described by Dawson and Rowlands[4]. The enzyme is therefore characterized as 'phospholipase *B*'.

Unlike any other phospholipase *B* from *Penicillium notatum*[5], *Aspergillus niger*[6] or from any animal tissue such as pancreas[7] and liver[8], this enzyme has a *p*H optimum of 8·0 and is fairly stable towards heat denaturation. It is destroyed only on heating at 100° C. for 15 min., and heating for 5 min. at that temperature causes about only 50 per cent inactivation. It is fairly insensitive towards metal ions, and when used at a final 1 m*M* concentration only zinc causes about 40 per cent inhibition, whereas copper, manganese, calcium and magnesium have practically no effect. Of the inhibitors studied at 10^{-3} *M* final concentration, cyanide, azaguanine and chloramphenicol have no effect, azide and dinitrophenol inhibit the enzyme to the extent of about 15–20 per cent, whereas sodium fluoride, versene and *p*-chloromercuribenzoate individually cause about 45 per cent inhibition. The inhibition by versene and by *p*-chloromercuribenzoate can be fully reversed by the addition of calcium and glutathione respectively. It has further been observed that glutathione and also cysteine bring about some stimulation of the enzyme. Work on the properties and also on the mechanism of excretion of this enzyme by both *Vibrio cholerae* and *Vibrio* El Tor is in progress.

We wish to thank Prof. B. C. Guha for his advice and interest in this work, and also Dr. R. M. C. Dawson, Cambridge, England, for his gift of a sample of glycerophosphoryl choline.

Immunity of Bee Keepers to Some Constituents of Bee Venom : Phospholipase-*A* Antibodies

FOR many years bee venom has been used in the treatment of arthritis and rheumatism, but with little evidence of its value[1]. Bee venom contains three important constituents : the main toxic fraction I, and the enzyme fraction II, containing phospholipase and hyaluronidase. Each enzyme has been isolated in pure form[2,3]. The hæmolytic effect of the venom on blood corpuscles is caused directly by the toxic fraction I, and indirectly by the phospholipase-*A* activity[4]. Among other effects of phospholipase-*A* is retardation of egg yolk coagulation[5].

Antibodies against the toxic fraction have not been found ; those against the enzymatic part of the venom have been demonstrated in the sera of mammals injected with bee venom for a long time[6,7]. We have therefore examined the sera of bee keepers to ascertain whether they contain antiphospholipase bodies.

Samples of blood from bee keepers were taken as test samples, and from ordinary men as control samples. The blood was left to clot at room temperature, then placed in a refrigerator overnight. Serum, obtained by centrifuging and decanting, was kept in a refrigerator until required. Natural bee venom was dissolved in physiological saline (0·85 per cent) in concentrations of 1 : 1,000, 1 : 2,000 and so on up to 1 : 64,000.

To 0·05 ml. bee keeper serum were added 0·05 ml venom solution and, after at least 15 min. at room temperature, 2 ml. of egg yolk diluted with physiological saline in the proportion of 4 : 6. The mixture was shaken, heated for 1 hr. in a water-bath at 37° C., and the tubes then plunged into boiling water and the time of coagulation recorded with a stop watch. The emulsion was considered to coagulate when no traces of the egg yolk adhere to a thick glass rod inserted repeatedly into the tubes containing the mixture. Two control experiments were carried out in the same way, one with normal serum and the other with saline instead of serum.

The methods of calculation were as follows:

Venom end concentration: 0·05 ml. venom was added to 0·05 ml. serum and 2·0 ml. egg yolk; the final dilution was 0·05 : 2·1 = 1 : 42. When original venom concentration is 1 : 2,000, the end concentration is 1 : 84,000.

Serum end concentration: 0·05 ml. serum was added to 0·05 ml. venom and 2·0 ml. egg yolk; the final dilution was 0·05 : 2·1 = 1 : 42. Serum itself was used without original dilution, therefore its end concentration is the same as the final dilution = 1 : 42.

Serum in ml. : Venom in gm.: 1 : 42/1 : 84,000 = 2,000 : 1.

Effect of serum of normal men: This is considered as activity if the time of coagulation is more prolonged, and as inhibition if time is shorter, than time of control; for example, average control saline = 24·8, average control serum of normal men = 26·3; effect of normal serum

$$= \frac{26 \cdot 3 - 24 \cdot 8}{24 \cdot 8} \times 100$$

= 6 per cent activation.

Effect of serum of bee keepers: The effect was related to the effect of serum of normal men; for example, average control serum of normal men = 26·3, average test serum of bee keepers = 21·6; effect of bee keepers serum

$$= \frac{26 \cdot 3 - 21 \cdot 6}{26 \cdot 3} \times 100 = 18$$

per cent inhibition.

The results obtained in a series of experiments are summarized in Table 1.

Table 1. Effect of Sera from Bee keepers and Control on the Coagulation-time of Egg-yolk

	Venom original concentration	Control saline	Control serum	Test serum
	1 : 2,000			
Mean coagulation time (min.)		24·8	26·3	21·6
Standard error of mean		4·28	4·88	4·56
	1 : 4,000			
Mean coagulation time (min.)		9·8	10·1	9·7
Standard error of mean		0·4	0·26	0·88
	1 : 8,000			
Mean coagulation time (min.)		4·8	4·9	3·0
Standard error of mean		0·57	0·30	0·41
	1 : 16,000			
Mean coagulation time (min.)		2·7	2·0	1·7
Standard error of mean		0·41	0·28	0·16

The above figures represent the averages for 4 saline controls, 6 normal sera controls and 10 bee keepers sera.

From Tables 1 and 2, it is clear that normal serum has no antiphospholipase effect against high final concentration of venom (1 : 2,000, 1 : 4,000 or 1 : 8,000). In the first two concentrations the activity of the enzyme was increased. Serum from bee keepers showed an inhibitory effect on the enzyme at previous concentrations; it reached more than 40 per cent in concentrations of 1 gm. venom to 4 litres serum.

Table 2 shows that phospholipase-*A* of bee venom was activated by serum of normal men when the concentration of the latter to that of venom was 2,000 : 4,000 : 1, and 8,000 : 1. Very dilute concentrations of 16,000 : 1 were inhibited by normal serum. Serum of bee keepers inhibited the phospholipase-*A* effect in all concentrations used.

Table 2. Quantitative Comparison of Inhibition of Phospholipase-*A* Activity by Sera of Normal Men and Bee keepers

Venom end concentration	Serum end concentration	Serum : Venom (ml. : gm.)	Effect of serum of normal men	Effect of serum of bee keepers
1 : 84,000	1 : 42	2,000 : 1	activation, 6 per cent	inhibition, 18 per cent
1 : 168,000	1 : 42	4,000 : 1	activation, 3 per cent	inhibition, 4 per cent
1 : 336,000	1 : 42	8,000 : 1	activation, 2 per cent	inhibition, 39 per cent
1 : 672,000	1 : 42	16,000 : 1	inhibition, 25 per cent	inhibition, 15 per cent

In low concentrations of venom, such as 1 : 16,000, both normal serum and bee keepers' serum showed an inhibition of phospholipase-*A*; the latter being about 10 per cent more inhibitory.

We thank the Council for Combined Units for facilities in obtaining blood samples from bee keepers working in its apiaries; Dr. K. A. Forster, for providing carefully dried bee venom prepared by Mack Company, Illertissen, Germany; Blood Bank of Ain Shams University, for samples of normal blood of different blood groups; and Dr. M. Shabrawi for useful help.

PHYSIOLOGY

Effect of Urinary *p*H on 5-Hydroxytryptamine Excretion in the Rat

Urinary *p*H influences the excretion-rate of some weak acids and bases[1,2], a more rapid excretion of weak acids occurring in alkaline urine and of weak bases in acid urine. Most of the known compounds which behave in this way are not found naturally

Female white Wistar rats of 200–250 gm. body-weight were depleted of sodium chloride by the dietary method of Milne *et al.*[4]. Two rats, matched for weight, were used in each experiment. One was injected intraperitoneally with 10 ml. isotonic sodium sulphate ('acid rat' – urine pH 5·5–6·0 throughout experimental period) and the other with 10 ml. isotonic sodium bicarbonate containing 10 mgm. acetazolamide ('alkaline rat' – urine pH 8·0–8·5 throughout experimental period). The injection solutions also contained 30 mgm. per kgm. body-weight of β-phenyl*iso*propylhydrazine ('Cavodil'). One hr. later an indwelling catheter was placed in position under pentobarbitone–ether anæsthesia which was continued throughout the experiment. After 1·5 μc. DL-^{14}C-5-hydroxytryptophan (exps. 1–5) or 1·5 μc. ^{14}C-5-hydroxytryptamine (exps. 6–8) had been injected intraperitoneally, hourly collections of urine were made. Bladder washings of 3 × 1 ml. isotonic sodium chloride, obtained at the end of each hour, were added to urine excreted during that hour.

Specimens of urine were analysed for total number of counts and portions were also extracted (refs. 5, 6) and assayed for ^{14}C-labelled 5-hydroxytryptamine or 5-hydroxyindoleacetic acid using a thin end-window Geiger counter.

in the body. The only endogenous substances so far described, the excretion-rate of which is dependent on urinary pH, are ammonia[3] and indoleacetic acid[4]. We present evidence here to show that the rate of excretion of 5-hydroxytryptamine (5HT) is similarly influenced by pH, being higher in acid urine (Table 1).

Data from man indicate that 5HT is normally present in the urine in low concentration[7], although larger amounts are found after parenteral administration of 5-hydroxytryptophan (5HTP)[8] and in patients with certain tumours[9]. The level probably depends to an appreciable extent on the amount of 5HTP presented to the kidney for direct renal decarboxylation. In rats used in experiments described here, the rate of 5HT excreted was greater after 5HTP injection than after 5HT (Table 1). Presumably most of the free extra-renal 5HT was either rapidly metabolized or absorbed by platelets. In these animals monoamine oxidase had been blocked with β-phenyl*iso*propylhydrazine to prevent further renal metabolism of 5HT. The absolute amounts of 5HT labelled with carbon-14 used were probably insufficient to interfere with renal hæmodynamics.

It will be seen (Table 1) that there was a fairly wide variation in 5-hydroxyindole excretion between experimental groups, which may be accounted for, to some extent, by differences in such variables as depth of anæsthesia. Anæsthesia and environment of the pair of animals used in each single experiment were similar however, so that despite the between-group variation, the tendency of the 'acid rat' to excrete 5HT more rapidly than the 'alkaline rat' (Fig. 1) is probably significant.

After 5HTP administration, increased rate of 5HT excretion in the 'acid rat' is complemented by a decrease in 5-hydroxyindoleacetic acid (5HIAA) excretion and vice versa (Table 1). However, as 5HIAA is known to have an active transport mechan-

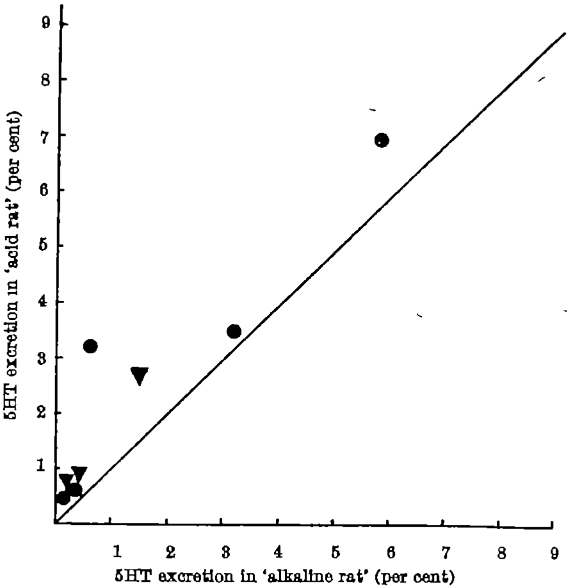

Fig. 1. Excretion of 5-hydroxytryptamine (5HT) in acid and alkaline urine expressed as percentage of total counts injected. ▲, 5HT administration; ●, 5HTP administration

ism for its renal elimination[4,10] these changes presumably reflect the absolute amounts of 5HT involved; if more is excreted by the kidney, less is available for conversion to 5HIAA. In experiments 6–8, however, in which 5HT itself was administered, the concentrations of urinary 5HT probably form too small a fraction of the total excretion of 5-hydroxyindole metabolites to produce any experimentally obvious reciprocal change in 5HIAA values. The mechanism of 5HIAA production under conditions of heavy monoamine oxidase blockade, which has been observed by many workers, is not understood.

From theoretical considerations[1], it is rather surprising that such a lipid-insoluble compound as 5HT[11] is excreted by a non-ionic diffusion mechanism. Elucidation of this problem must await further study. But one practical implication of the work that we have described is that investigations in which urinary 5HT measurements have been used as an index of 5HTP decarboxylase activity[12,13] will probably need re-evaluation.

We are grateful to Benger Laboratories, Ltd., for generous supplies of 'Cavodil'.

Influence of Sodium on the Transport of Magnesium across the Intestinal Wall of the Rat *in vitro*

SINCE the first description of hypomagnesæmia in adult cattle by Sjollema and Seekles[1] there have been numerous investigations into the underlying causes of this condition. Herbage analysis of the pasture where the disease has occurred shows that it is not usually due to an absolute dietary deficiency, although Norwegian workers[2] have shown that this may occasionally be so. It has been suggested that the absorption of magnesium may be impaired when cattle or sheep are suddenly moved to rapidly growing young pastures. Head and Rook[3] have suggested that this may be due to the accumulation of ammonia in the rumen, and Kemp and 'T Hart[4] have provided evidence which has incriminated high levels of potassium in the pasture at this time.

In an attempt to find out more about the factors which influence the availability of magnesium to the animal, a series of experiments has been undertaken using an *in vitro* preparation of rat small intestine[5] in which oxygenated Krebs's bicarbonate saline[6] containing 0·5 per cent glucose is circulated through the intestinal lumen, and the water and solutes which are transported to the serosal surfaces are collected below. Magnesium has been estimated, using a slight modification of the method of Mann and Yoe[7], and sodium, using an EEL flame photometer.

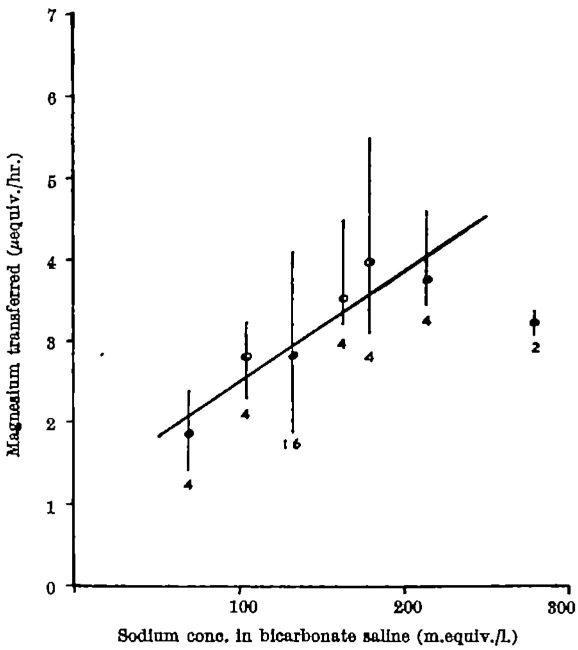

Fig. 1. Relation between magnesium transferred per hr. and sodium concentration in the bicarbonate saline. Vertical line shows range of results. Number below indicates number of experiments. Points are arithmetic means. ○, young rats; ●, old rats.

The amount of magnesium (μequiv./hr.) transported to the serosal surface was found to vary when the circulating concentration of sodium chloride was altered. This is shown graphically in Fig. 1, where the regression line for 36 readings has been drawn (magnesium transferred = 0·015 sodium concentration − 0 92; correlation coefficient $r = 0{\cdot}65$; $P < 0{\cdot}001$). The concentration of the other ions in the bicarbonate saline remained unaltered. The two experiments in which the concentration of sodium was highest (280 m.equiv./l., that is, an increase of 137 m.equiv./l. over Krebs's bicarbonate saline) have been omitted when the regression line was calculated. At this concentration the volume of water transported was reduced from a normal value of 2–7 ml. to less than 1 ml./hr., confirming the findings of Smyth and Taylor[5] on the effect of increasing osmotic pressure on such a preparation.

Two groups of rats were used in the experimental work, and it will be seen from Fig. 1 that the mean values for the younger group (about 12 weeks old) invariably fell above the regression line, but the means for the older group (about 20 weeks old) were below the line. This suggests that the younger group were the more efficient at transporting magnesium to the serosal surface.

The effects on magnesium transport of the addition of ammonium chloride, and increasing the potassium concentration in the circulating solution (from a normal value of 5·9 m.equiv./l.) by the addition of potassium chloride, are shown in Table 1, and are compared with the results for Krebs bicarbonate saline. It will be seen that neither of these salts

Table 1

Concentration in bicarbonate saline (m.equiv./l.)	Magnesium transported (μequiv./hr.)	No. of experiments
K^+ – 27	2·97	3
K^+ – 40	2·72	2
K^+ – 84	2·72	1
NH_4^+ – 20	3·01	2
NH_4^+ – 100	2·82	1
Krebs's bicarbonate saline K^+ – 5·9 ; NH_4^+ – 0)	2·81	16

appears to influence the transport of magnesium under these conditions. The influence of sodium chloride on magnesium transport is therefore probably due to the sodium rather than to the chloride ion, since the chloride was common to all three salts.

It is interesting to note that the association between sodium and magnesium transport across the intestinal wall, reported here, is similar to that recently described for the human kidney[8], where the rate of excretion of magnesium was found to vary directly with the concurrent excretion of sodium chloride.

The relation of these findings to ruminant hypomagnesæmia is difficult to evaluate, since the conditions in this *in vitro* preparation of rat small intestine are very different from those of the ruminant gastrointestinal tract, although it does suggest that attention should be given to the influence of varying sodium-intake on magnesium absorption in the intact animal.

This work was carried out during the tenure of a Vitamealo research fellowship awarded by the Animal Health Trust. I wish to thank Mr. A. A. Wilson for his advice and encouragement.

Clinical Application of a Serological Method for the Determination of Human Chorionic Gonadotrophin

It was early observed that prolonged administration to animals of gonadotrophic hormone from human pregnancy urine was accompanied by gradually diminished effects[1]. This phenomenon has been found to be due to the formation of an anti-gonadotrophic factor demonstrable only by its capacity to impair the gonadotrophic reaction in rodents[2]. Previous to our earlier report[3], there had been no demonstration of the antigonadotrophic factor by serological *in vitro* methods. Precipitating and complement-fixing antibodies had been obtained by immunization of rabbits with gonadotrophic hormone prepared from human pregnancy urine[4,5]. These antibodies, however, were shown to be due to contaminating, antigenically active substances[6].

In contrast to these investigators, we have been able to demonstrate that human chorionic gonadotrophin can stimulate the production, demonstrable *in vitro*[3], of antibodies against itself. This was accomplished by the inoculation of a purified human chorionic gonadotrophin preparation (Gonadex-Leo, supplied by courtesy of Dr. Högberg, AB Leo, Halsingborg, Sweden) together with an adjuvant into a heterologous species (rabbit). The presence of human chorionic gonadotrophin antibodies in the rabbit sera was demonstrated with the complement fixation test. With these antisera, human chorionic gonadotrophin could then be determined in serum as well as in the urine of pregnant women by means of this serological test. Two other reports, in principle confirming our results, have since been published. These showed that the estimation of human chorionic gonadotrophin in urine was possible with the precipitin test[7] and the hæmagglutination inhibition reaction[8].

In further experiments we have been particularly interested in evaluating the sensitivity and specificity of our serological procedure for the determination of human chorionic gonadotrophin with a view to its clinical applicability. From practical as well as physiological considerations, we have preferred to analyse serum rather than urine.

Preparation of antisera. Twelve rabbits were immunized, each with 12,500 I.U. of human chorionic gonadotrophin in adjuvant (10 parts of the hormone in saline, 8·5 parts paraffin oil and 1·5 parts 'Arlacel *A*', the mixture containing 10 mgm. of finely powdered *Mycobacterium butyricum* per 100 ml.) administered in a total volume of 20 ml. on three occasions at intervals of three weeks. The mixture was given at four sites subcutaneously and intramuscularly. A booster injection of 3,000 I.U. of the hormone in saline was given intravenously four to six weeks after the last inoculation. Blood was withdrawn by cardiac puncture one week after the booster injection. Serum was separated, heated at 56° C. for 30 min. and stored at –20° C.

Serological technique and standardization of antisera. The rabbit sera were tested for the presence of human chorionic gonadotrophin antibodies in complement fixation tests against the hormone dissolved in sera from non-pregnant individuals. The tests were carried out as 'chess-board' titrations according to the plate technique of Fulton and Dumbell[9] as modified by Svedmyr, Enders and Holloway[10]. Twofold serial dilutions were employed with barbiturate buffer as diluent. Simultaneous complement titrations with antigens, antisera and diluent were included in each experiment to rule out false positive reactions due to anticomplementary effects.

All antisera were tested against sera from non-pregnant women. Most rabbit sera gave negative results. With a few antisera positive reactions in low-antiserum titres of the type described earlier were encountered[3]. These reactions could be completely overcome by means of a simple absorption procedure[3].

The antisera were then tested with a solution containing 1,500 I.U. of the hormone; its concentration was checked against the international standard. A typical 'chess-board' titration is shown in Table 1. The hormone solution diluted 1/6,400 still gives positive reactions, which implies that with this anti-

Table 1. 'CHESS-BOARD' TITRATION OF HUMAN CHORIONIC GONADOTROPHIN WITH SERUM FROM RABBIT IMMUNIZED WITH THE HORMONE

Antigen	Dilution of antigen	Dilution of antiserum 8	16	32	64	128	256	512
Human chorionic gonadotrophin 1,500 I.U. per ml.	50	+	+	+	+	−	−	−
	100	+	+	+	+	+	−	−
	200	+	+	+	+	+	+	−
	400	+	+	+	+	+	+	−
	800	+	+	+	+	+	+	−
	1,600	+	+	+	+	+	+	−
	3,200	−	+	+	+	+	+	−
	6,400	−	−	+	+	−	−	−
	12,800	−	−	−	−	−	−	−

serum 0·25 I.U. of human chorionic gonadotrophin per ml. can be determined. The maximal titres of the hormone solution varied from 3,200 to 12,800. From Table 1 it is apparent that antiserum diluted 1/32 is suitable for carrying out quantitative determinations of the hormone in a routine procedure. This has also been confirmed in 'chess-board' titrations with specimens from pregnant women.

Clinical investigations. Blood samples were collected from 194 patients. Serum was separated, heated at 56° C. for 30 min. and stored at −20° C. until examined. 148 women were pregnant. Pregnancy was diagnosed by gynæcological examination and in early cases by biological pregnancy tests[11]. (The biological pregnancy tests were performed at the Hormone Laboratory of the Department of Obstetrics and Gynæcology, Karolinska Sjukhuset.) As all samples were collected 3–7 months before testing, all cases were also checked by follow-up. With the serological determination procedure of chorionic gonadotrophin, all specimens from pregnant women gave positive results. No false positive reactions were found. Fig. 1 illustrates the quantitative results obtained with sera from pregnant women varying in gestational stage from 5 to 42 weeks. The titres vary from 2 to 1,024 corresponding to 0·7 to 340 I.U. of hormone per ml. serum. The highest titres were observed during the first trimester. High values were, however, also found late in pregnancy.

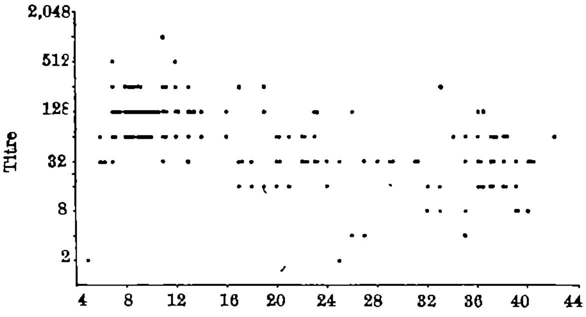

Fig. 1. Results of serological determination of human chorionic gonadotrophin in serum of 148 pregnant women. (According to standardization tests, a minimal amount of 0·35 I.U. of the hormone per ml. could be determined with the antiserum used)

These results indicate that the serological procedure presented here is a sensitive and specific method for the determination of human chorionic gonadotrophin. Its suitability for the diagnosis of pregnancy seems apparent. The fact that the test can be performed on serum increases the clinical importance of the quantitative data obtained. Work is now in progress on quantitative serological analyses of human chorionic gonadotrophin in serum in various pathological conditions. We are also planning simultaneous quantitative biological and serological determinations of the hormone.

Subjective Analysis of Saccadic Eye Movements

IN the course of an investigation into the mechanics of eye movements, using mainly electrical recording methods[1], some of the findings have been checked by a simple subjective method. This enables an observer to examine his own saccades, which he sees traced out before him in the form of displacement-time curves.

The subject views, from a distance of about 50 cm., a cathode ray oscilloscope, on which is a straight horizontal line, generated by a time-base running at a velocity between 20 and 50 cm./sec. When small downward vertical saccades of a few degrees extent are made, a tracing of the type shown on the left of Fig. 1 is seen, and when upward vertical movements are made, the tracing is usually that shown on the right. An explanation of how the effects are produced follows that given by Crookes[2], to explain the visual sensations accompanying saccadic movements across a television screen.

The effects are best seen in a darkened room, and are particularly clear for downward movements which start a few centimetres above the line, and end on the line, in which case the overshoot is seen just above the level of the line. If much larger saccades, of about 30°, are made, starting above the oscilloscope and ending on the line, the overshoot is seen to be only slightly larger than for 3° saccades (average values ½° and ½° respectively). With a double-beam instru-

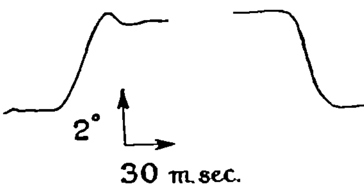

Fig. 1. Vertical saccades recorded with capacitance gauge

ment, two parallel curves appear to be traced out by the two spots.

When observation is made by reflexion in a mirror, so that the oscilloscope spot appears to travel from right to left, the traces are now reversed. Horizontal eye movements can be examined by either tilting the head, leaving the instrument fixed, or by rotating the oscilloscope so that the line is vertical.

Twelve subjects have perceived the effects, without difficulty, and have been able to estimate the duration of their own saccades and the dependence on the amplitude of the saccade. Reports differ slightly in the amount of overshoot, but agree that it is larger in downward movements, and that its magnitude is largely independent of the extent of the movement. In horizontal saccades this asymmetry appears to be less pronounced.

These subjective observations, in which there is no interference with the eye in any way, are consistent with my own experimental results, and with those of Byford[3], who has recorded eye movements by attaching a lamp to a contact lens. They do not support the model of saccadic eye movements put forward by Westheimer[4], on the basis of his own measurements.

A detailed analysis of the overshoot phenomenon is to be reported elsewhere.

Breakdown of Seminal Glycerylphosphorylcholine by Secretions of the Female Reproductive Tract

IN the course of experiments on the metabolism of glycerol by ram spermatozoa, the seminal plasma was found to contain high concentrations of a substance estimating as glycerol[1]. This was identified as a glycerol complex, namely, glycerylphosphorylcholine, which was shown to occur in ram seminal plasma in a concentration of more than 1 per cent, and in the semen of the bull, goat, stallion, man and rabbit in lesser amounts[2]. Despite its high concentration in the seminal plasma, however, ram spermatozoa are unable to metabolize glycerylphosphorylcholine[2], and its physiological significance has hitherto been unknown.

On the other hand, it is well established that ram spermatozoa can utilize free glycerol, or phosphoglycerol, under aerobic conditions with the formation of lactic acid, which can be further oxidized to carbon dioxide and water[1,3]. It occurred to us, therefore, that there might be an enzyme in the secretions of the female tract capable of splitting choline from the glycerylphosphorylcholine molecule and thus liberating glycerol or phosphoglycerol that could be utilized by the spermatozoa, since conditions in the female tract are believed to be essentially aerobic[4]. This has proved to be so and the evidence is outlined in this preliminary communication.

Secretions were expressed from the uterus and Fallopian tubes of freshly slaughtered ewes, or washed out with Ringer solution. When 0·5 ml. of this fluid was incubated at 37° C., either overnight (7 experiments) or for 3 hr. (14 experiments), with 0·1–0·5 ml. of ram seminal plasma, a highly significant ($t = 5{\cdot}2$, d.f. $= 12$, $P < 0{\cdot}001$; and $t = 4{\cdot}5$, d.f. $= 26$, $P < 0{\cdot}001$ respectively), though somewhat variable, increase in free choline, as estimated by methods previously described[2], occurred. On the average, about 30 per cent of the glycerylphosphorylcholine was broken down in 3 hr. and about 50 per cent overnight. Thus appreciable quantities of metabolizable end-products (namely, glycerol or phosphoglycerol) are likely to be produced following the introduction of seminal glycerylphosphorylcholine into the female tract. The variability in free choline liberated is not unexpected, since it was only possible in these preliminary tests to calculate the results in terms of the volume of fluid washed from the female tract rather than on the basis of dry weight or protein content. Large variation in the composition of the uterine fluid itself might also be expected, depending on the stage of œstrous cycle[5].

No significant increase in free choline was found when the secretions of the reproductive tract of the ewe, or the seminal plasma of the ram, were incubated separately. The increase in free choline on mixing the secretions followed a fairly linear course during 3 hr., and could be almost exactly accounted for by the disappearance of glycerylphosphorylcholine. Thus, in three experiments a mean of 426 μgm. of free choline was liberated per ml. of incubation medium and 392 μgm. of glycerylphosphorylcholine–choline lost.

The liberation of free choline is clearly not due to bacteria, since it was unaffected by bacteriostatic concentrations of a mixture of penicillin and streptomycin. On the other hand, the increase in free choline was completely abolished by heating the secretions of the female tract for 5 min. at 100° C., suggesting that an enzyme, probably a diesterase similar to that found in the liver[6], is responsible. Similar investigations have shown that the enzyme is also present in the secretions of the reproductive tract of the cow and the sow.

In view of the apparent widespread occurrence of this enzyme in the female secretions, it is suggested that glycerylphosphorylcholine might be an important source of energy for spermatozoa in the female tract after copulation, despite the fact that spermatozoa themselves may not be capable of breaking down the intact molecule. It is interesting in this regard to compare glycerylphosphorylcholine with the better-known seminal constituent, fructose[7]. This sugar, which is readily utilized by spermatozoa, is produced by the seminal vesicles or prostate and is not normally mixed with the spermatozoa until after ejaculation[7]. Glycerylphosphorylcholine, on the other hand, is chiefly found in the epididymal fluid of the larger species[2], and, although always in intimate contact with the spermatozoa, can only be utilized by them after the semen has come into contact with the female secretions. The occurrence of a glycerylphosphorylcholine-splitting enzyme in the female secretions would seem to constitute a rather novel method of ensuring that spermatozoa have an additional source of energy available to them in the female tract.

The enzyme is now being further characterized, and full details of the work will be published elsewhere.

We are indebted to Prof. C. W. Emmens for his interest in this work, and to Mr. P. Bryden of

the New South Wales State abattoirs for his co-operation in obtaining experimental material. The work has been supported by grants from the Planned Parenthood Federation of America and the Wool Research Fund.

Lipoprotein Composition of the Film lining the Lung

SMALL bubbles (~ 50μ diam.) in air-saturated water usually contract and disappear within a few minutes. In similar circumstances, however, small bubbles derived from animal lungs are stable. This is due[1] to their surface tension being reduced to 0·05 dyne/cm. or less by an insoluble surface film. This film is derived from the original film lining the lung alveoli; its (oven-dry) mass is about $6 \cdot 4 \times 10^{-7}$ gm./cm.[2]. *In situ* it annuls the tension of the sharply curved alveolar surface, which would otherwise give rise to transudation from the blood or to atelectasis[2]. For various reasons the film was at first thought to consist of mucoprotein.

Specimens of the substance lining the bubbles have now been isolated. Water was forced down the main bronchus into the excised lung of a cow, and was then allowed to well out, laden with bubbles. These bubbles were then washed with ten changes of water, so as to remove all dissolved matter and suspended solids. A sample of the washed froth, dried at 40° C., left a pale brown solid of waxy consistency.

This residue was examined in the form of a cast film on a potassium bromide plate by infra-red absorption spectroscopy, a model 137 Perkin–Elmer spectrophotometer being used. The spectrum, and that of a mixture of purified egg lecithin (95 per cent) and gelatin (5 per cent) for comparison, are shown in Fig. 1. Qualitatively, the curves are identical. The relative intensities of the ester carbonyl bands at 5·75μ and the amide bands at 6·1μ and 6·5μ in the two spectra suggest that the proportion of protein in the bubble lining is about 1 per cent. The presence of small amounts (< 1 per cent) of other lipids or of carbohydrates cannot be excluded, but it is clear that the lining film consists in the main of a lecithin–protein complex; the very low value of the protein content suggests that some of the lecithin present may be adventitious.

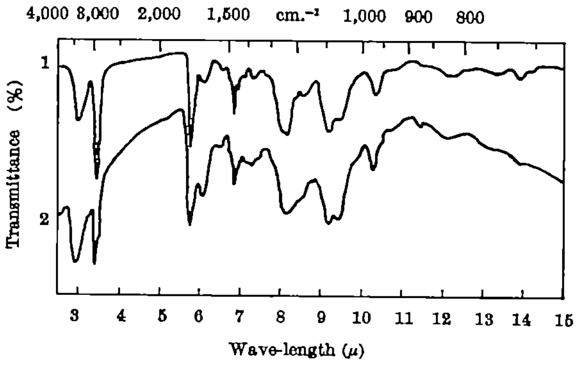

Fig. 1. Percentage transmission (on arbitrary scale) of infra-red radiation through (curve 1) lung bubble lining substance and (curve 2) mixture of 95 per cent lecithin and 5 per cent gelatin

Small stable bubbles have also been obtained from other sources. They are formed, for example, when dry powders of a bacterial lipopolysaccharide[3], of thromboplastic lipoprotein[4], or of acetone-washed egg yolk, are wetted. They may also be obtained by wetting acetone-dried or freeze-dried tissues (muscle, brain, etc.).

Lipoprotein complexes are known to form readily[5,6]. When, for example, lecithin (4 gm.) and gelatin (1 gm.) are ground to a paste with water, and the paste is dried with acetone, a leathery porous substance results; this, when wetted and squeezed under water, yields stable bubbles. It may therefore be that some of the bubble-stabilizing substances found in dried tissues are artefacts which are not present *in vivo*.

Effect of Exposure to Sun and Exercise on Heat Tolerance Coefficient in Murrah Buffalo Calves

IN continuation of our previous work[1], this experiment was designed to find out the effect of exposure to sun and exercise on heat tolerance coefficient. Eight Murrah buffalo calves, varying between 8 and 12 months of age, constituted the experimental material. These calves were randomly divided into two groups of four each. One group was exposed to sun, while the other ran at a speed of four miles per hour as recorded by the distance covered in a given time. The calves in each group acted as their own control. These experiments were conducted at 12 noon for half an hour on six consecutive hottest days in the month of May. The atmospheric temperature during test hours ranged between 92 and 105° F. and relative humidity between 28 and 47 per cent. The conditions of management of these calves has been given in detail[2].

The heat-tolerance coefficient was calculated daily for each animal, as control and after exposing them to sun or exercise, by Rhoad's formula[3]. The variations were analysed statistically[4].

Table 1 indicates mean value, variance, standard deviation, and coefficient of variation of the atmospheric temperature, relative humidity and heat-tolerance coefficient. There seems to be a degree of consistency in the mean values of the controls of the

Table 1. Heat Tolerance Coefficient

	Temperature		Humidity		First group		Second group	
	Under shade	In sun	Under shade	In sun	Control (in shade)	Exposed to sun	Control (in shade)	Put to exercise
Mean	93 66	98 00	42·00	32 66	92·38	80·80	94·04	65·00
Variance	1·48	16·40	10·40	43·48	62·14	68·86	19 52	185·78
Standard deviation	1·21	4·04	3 22	6 52	7·88	9·31	4·42	13·62
Coefficient of variance (per cent)	1·29	4 12	7·66	20·11	8·53	11·5	4 90	20 95

two groups, but F value indicates ($F_{24,24} = 3 \cdot 1$; $P_{1\%} = 2 \cdot 66$) that the variation between the controls of the two groups is significant. As such these values could not be pooled together to test the differences between the two different groups. However, the variance ratio in the first and the second group when compared with their own controls were 1·39 and 9·51 respectively ($F_{22,22}$ 5 per cent $= 1 \cdot 98$). Since variance of heat tolerance coefficient in the first group was not significant, the t test was applied for testing the differences between the two means ($t_{24} = 2 \cdot 39$; P_{24} 5 per cent $= 2 \cdot 06$). These two mean values were found to be significant.

Table 2 indicates that there were significant differences in heat tolerance coefficient of the calves before and after exposure to the sun. The calves of the other group when put to exercise showed significant differences in their heat tolerance between themselves, between days and between treatment. Every animal behaved differently for its capacity to withstand the thermal stress on different days to the exercise given.

Table 2. Analysis of Variance

Sources of variation	*d.f.*	Mean square	
		First group Effect of exposure to sun	Second group Effect of exercise
Between animals	8	158 58	61·40*
Between days	5	187 08	375·38*
Between treatment	1	1,598 52*	10,120·84*
Between animal × days	15	43·62	29·21*

Between days × treatment	5	13·62	403 45*
Between animal × days × treatment	15	76 65	7 23

* Significant at 1 per cent level.

The buffalo calves after exercise were observed seeking the shade and in distress characterized by licking, panting and general restlessness. Drooling appeared when the increased respiratory activity proved unsuccessful in stabilizing body temperature. These are physical homœothermic mechanisms which ease the burden of heat load on the animal[5]. The ability of the buffalo calves to withstand the tropical heat, especially when exposed to the sun or put to exercise, seemed to decrease, perhaps because of the increased heat production and absorption[6]. The black pigmented hide absorbs the infra-red rays of solar radiation and thus limits the animal's adaptability to exposure to sunlight. In the shade, however, the black coloration aids heat dissipation[7]. Adaptation to hot humid climate is characteristic of the buffaloes. The thick skin of the buffalo calves may prevent heating of the body from hot air and by radiation from the sun or hot ground. The buffalo calves, although surviving in hot zones when humidity is high, essentially require shade and cooling systems for their comfort[8].

HÆMATOLOGY

A Notation for the Gm Groups

The following met in Rouen in April 1960 to discuss notation and other matters regarding the Gm serum protein groups of man: A. Eyquem, Institut Pasteur, Paris; H. Fudenberg, Rockefeller Institute, New York; R. Grubb, Bacteriological Institute, Lund; M. Harboe, Institute for Thrombosis Research, Oslo; S. Lawler, Galton Laboratory, London; J. Moullec, Centre National de Transfusion Sanguine, Paris, represented by C. Henry; L. Podliachouk, Institute Pasteur, Paris; C. Ropartz, Centre Départemental de Transfusion Sanguine, Rouen; A. Steinberg, Western Reserve University, Cleveland; A. Tiilikainen, Department of Serology and Bacteriology, University of Helsinki. The following statement has been prepared.

It is increasingly apparent that the Gm system is complex and our aim is to minimize confusion originating in differing nomenclature or standards.

To be accepted as part of the Gm system a character must be shown to be contained in the gamma-globulin fraction, and its relationship to the known Gm factors demonstrated by genetical and/or population studies.

The characters to be considered at the present state of knowledge are Gm(a), Gm(b), Gm(x) and Gm-like as originally described in references 1–6 respectively.

Symbols for genotypes and phenotypes should be clearly distinguishable. In conformity with the suggestions of Ford[7], we will adhere for Gm notation to the two following rules: (1) the use of italics for gene symbols and the use of ordinary type for phenotypes; (2) the use of suffixes for genes, but not for phenotypes. Example: Gm^a for the gene, Gm(a +) for the phenotype.

The use of gene symbols containing the suffixes a_1 and a_2 for specified characters has been suggested[8]. This proposal is now withdrawn. At the present state of knowledge no further suggestions for the gene symbols seem warranted.

The notation which will be used for the phenotypes now known is as follows: Gm(a + b + x +), Gm(a + b + x −), Gm(a + b − x +), Gm(a + b − x −), Gm(a − b + x +) (Henningsen, unpublished observations confirmed by Harboe), Gm(a − b + x −), Gm(a − b − x −). The type Gm(a − b − x +) has not yet been encountered. This notation can readily be expanded to adopt new phenotypes as they may be found and/or be included in the Gm system. To denote the Gm-like character, Gm-like (+) or Gm-like (−) is added; for example, Gm(a + b + x −) Gm-like (+). The term Gm-like is regarded as temporary. So-called intermediates may be signified by ± ; for example, Gm(a ±). The gamma-globulin-levels in sera of unusual phenotypes should be determined and given.

The terms anti-Gm(a), anti-Gm(b) and anti-Gm(x), to which the classical noncommittal term 'reagin' may be added, will be used to denote the specificities of the substances (usually, if not always, macroglobulins) causing the agglutination of red cells coated with human incomplete antibodies.

Samples of normal human sera of at least some of the known Gm-types, which can be used as standards, will be supplied on request by me. Standard Gm-like (+) and Gm-like (−) samples are obtainable from A. Steinberg, Department of Human Genetics, Western Reserve University, Cleveland 6, Ohio, U.S.

Formation of Hæmosiderin and its Relation to Ferritin

Support for the hypothesis that the protein moiety of hæmosiderin is the same as that of ferritin can be found in the literature[1,2]. Iron tetrad (or, more recently, 'hexad'[3,4]) structures in a protein matrix characteristic of ferritin have been reported in electron photomicrographs of tissue sections variously interpreted as ferritin, hæmosiderin, aggregates of ferritin, etc.[3,5,6]. It is not uncommon, therefore, to consider both ferritin and hæmosiderin as being more or less identical. However, the results of our biochemical and histochemical work lead to opposite conclusions[7,8].

Before commenting further, it should be emphasized that in biochemical terms, as originally defined by Laufberger[9], the fundamental property that distinguishes ferritin from hæmosiderin is the solubility of ferritin in water. It must also be recognized, despite the common misconception to the contrary, that ferritin does take the Prussian blue stain[10]. Failure to recognize and to apply these principles introduces the possibility that 'hæmosiderin' in tissue sections might consist partially or entirely of ferritin.

We have observed with biochemical and histochemical techniques that, as the water-extractable iron (ferritin) of rabbit liver approaches 200 mgm. per 100 gm. of tissue, Prussian blue-positive granules (hæmosiderin) form in the parenchymal cells. This phenomenon is clearly observed when the iron is administered as iron dextran; with saccharated iron oxide, the phenomenon is also reproducible relative to the parenchymal cells. In the Kupffer cells, there is in addition, with the latter preparation an accumulation of stainable insoluble iron at an early stage. This Kupffer cell iron differs in several respects from that of the parenchymal cells; it is not under consideration at present.

At levels of iron load just preceding that at which the typical Prussian blue-positive hæmosiderin granules appear, the formation of several intracytoplasmic vacuoles in the parenchymatous cells adjacent to the portal regions can be observed. These vacuoles are 1–2μ in diameter, have irregular borders, tend to be in proximity to the nuclei and, most important, give a faint blue homogeneous colour on staining for iron. As the iron load is increased, the larger of these vacuoles begin to show typical dense, dark-staining Prussian blue granules. At this point, one can still identify faint light blue-staining material at the periphery of these vacuoles. With increasing iron load, only typical Prussian blue-positive hæmosiderin granules are evident. The light blue material observed at earlier stages can be removed by water extraction of cubes of liver (1–2 $mm.^3$). The quantity of iron recovered in the extract corresponds closely to the ferritin content of the liver, as determined by biochemical methods. The dense, dark blue-staining granules remain unaltered. We have recorded these events by colour photomicrography; this work will be published elsewhere.

From the above, the lack of clear-cut distinction between hæmosiderin and ferritin by electron and/or light microscopy on tissues which have not had the ferritin removed by water extraction can be explained. For example, a recent electron photomicrograph by Bessis and Breton-Gorius[11] shows sections composed of electron-dense particles in a matrix, linearly arranged in a crystal lattice. This, as well as publications by Richter[12] and Kerr and Muir[3], also show aggregates of electron-dense iron particles with little or no matrix. They are variously interpreted as being ferritin crystals, different forms of hæmosiderin, aggregated ferritin, etc. As our work on granules isolated after extraction of ferritin indicated that the two compounds were chemically distinct, we submitted our preparations to Dr. G. W. Richter for electron microscopy. The electronmicrographs showed closely aggregated electron-dense particles, but neither ferritin crystals nor even isolated 'tetrads' were evident. This collaborative work is being extended and will be published separately.

These observations indicate that hæmosiderin and ferritin are not only chemically but are also structurally dissimilar. They also suggest strongly that the hæmosiderin granule, at least of the rabbit liver parenchymal cell: (1) is a relatively amorphous condensation of electron-dense iron particles into an essentially protein-free aggregate; (2) that it consists mainly of ferric hydroxide; (3) that it originates in liver cell vacuoles through a process of degradation of the protein matrix of ferritin; (4) that the linearly arranged iron particles in a matrix correspond to the faint blue-staining material we have observed histochemically in parenchymal cell vacuoles. Because of the water-solubility of the latter material, we conclude it represents ferritin. This concept leaves room for intermediate stages between native ferritin and the apoferritin-free aggregates of ferric hydroxide particles.

Therefore it is recommended, in order to bring anatomical and biochemical nomenclature into agreement, that the term 'hæmosiderin' should be applied only when the compound under investigation is known to be water-insoluble. This division may be arbitrary in an anatomical sense, but it is easily and accurately applied and will preclude the misconception that hæmosiderin and ferritin are identical.

This investigation was supported in part by grant No. *AT*(04–3)–77 from the U.S. Atomic Energy Commission. Support was also received from the Donate Once Club of North American Aviation, Inc., Los Angeles, and Lakeside Laboratories, Milwaukee, Wisconsin.

An Attempt to produce Hæmolytic Disease in Lambs

RENDEL[1] attempted to produce hæmolytic disease of the new-born lamb by injecting 8 pregnant ewes with blood taken from the rams to which they were mated. As a result, 4 of the ewes produced immune antibodies which reacted with the red cells of their mates; but their lambs did not develop hæmolytic disease even though at least 2 of them ingested colostrum-containing antibodies which reacted weakly *in vitro* with their respective red cells. In these cases, no antibody could be detected on the lambs' red cells, and Rendel concluded that if hæmolytic disease occurred in lambs it must be rare.

This communication describes an experiment carried out on similar lines to those of Rendel. A ewe was chosen which one year previously had been immunized with the blood of a certain ram and which had made a strong immune antibody to the ram's red cells. This ewe was mated to the ram, and during the later stages of pregnancy was given a booster injection of the ram's blood which resulted in a sharp rise in serum antibody titre from only a trace reaction to a titre of 1/16,000. Twin female lambs were born to the ewe after the normal pregnancy time, and blood samples were taken from them before they had sucked, and at 4, 7, 10 and 24 hr. after sucking and at intervals thereafter. In addition, blood serum and milk samples were taken from the ewe before and after parturition.

Both the serum and colostrum samples taken from the ewe at the time of parturition were titrated against the lambs' precolostrum red cells, using a simple hæmolytic test. To 1 drop of a 2 per cent red cell suspension in saline, 1 drop of the serum or colostrum at the appropriate dilution was added. These were mixed and left for 15 min. when 1 drop of undiluted rabbit complement (rabbit serum, absorbed with sheep red cells) was added. The test was left at 32° C., shaken at hourly intervals and read after 4 hr. The highest dilution of antiserum showing definite hæmolysis was taken as a measure of the strength of the antibody. Using this test, it was found that the dam's serum and colostrum reacted with the red cells of both lambs to a titre of about 1/8,192–1/16,384. The samples of red cells taken from the lambs were therefore tested to see whether they were 'sensitized'. They were washed once in saline and to 1 drop of a 2 per cent saline suspension of the red cells, 2 drops of rabbit complement diluted ½ were added and the test incubated at 32° C. Readings were taken after 1 hr. No hæmolysis was observed in the precolostrum or 4-hr. red cell samples; but the red cells taken from the lambs 7 and 10 hr. after sucking showed partial hæmolysis. The 24-hr. samples showed complete hæmolysis as did samples taken 5 days after birth. Nine days after birth the lambs' red cells again showed partial hæmolysis on the addition of complement and by the seventeenth day there was no evidence of sensitization. The hæmatocrit of the blood samples fell sharply during the first 5 days after birth (from 44 to 27 per cent in one lamb and from 47 to 25 per cent in the other lamb); but a similar drop was observed in blood samples taken from control lambs during the first week after birth, so this was considered to be of no significance. An osmotic fragility[2] test was made on the red cells of one of the lambs taken 5 days after birth, that is, at a time when the cells were well coated with antibody, but there was no evidence that their fragility was in any way different

Table 1. ANTIBODY TITRES AGAINST LAMBS' RED CELLS

—, Not tested. * Titre expressed as the reciprocal of the highest dilution of antiserum giving definite hæmolysis.

from that of the red cells of the control lambs of comparable age. Both lambs in fact showed no abnormal symptoms and grew and developed normally.

When the lambs were about 2 months old, their red cells were tested against titrations of their own sera, and against their dam's serum, and colostrum samples taken during the first days after birth. Table 1 shows the results. Antibody appeared in both lambs' sera at about the same time that their red cells began to show sensitization, reached maximum levels at 10 hr. and then declined in titre until by the ninth day none was detectable.

0·4 ml. of red cells from one of the 2-month-old lambs was labelled with chromium-51 (ref. 3), incubated for 20 min. at 37° C. in 8 ml. of a 1-in-4 dilution of the dam's serum taken at parturition, washed and injected back into the same lamb. A blood sample taken 5 min. after the injection showed only a trace of radioactivity, indicating that the injected red cells had all been quickly eliminated from the circulation. This experiment was repeated, only this time the lamb's red cells were incubated in a 1-in-4 dilution of its own serum taken 1 day after birth when it had an antibody titre of 1/64. The red cells were again quickly eliminated from the circulation.

The situation was therefore found where two lambs failed to show any symptoms of hæmolytic disease even though their red cells were strongly sensitized by antibodies ingested from the dam via the colostrum. A similar condition was reported in calves by Chavez[4], who fed a calf with colostrum to which had been added anti-ox antibody produced in rabbits, and demonstrated that its red cells became coated with antibody. The calf showed no symptoms of hæmolytic disease. Kiddy, Stone, Tyler and Casida[5] isoimmunized cows with a bull's blood; but although the dams' sera and colostra reacted with the calves' red cells in their experiments, no antibody to the calves' own red cells could be found in the calves' sera and no antibody could be detected on their red cells. From these findings they suggested that the mechanism protecting the new-born calf was the absorption or neutralization of ingested antibodies by tissue or soluble antigens, thus preventing the antibodies from reaching the calf's erythrocytes and causing their destruction. This could not be the explanation of the failure to produce hæmolytic disease in the lambs, for not only were the red cells coated with antibody, but at the time at which there was maximum *in vivo* sensitization there was also free antibody circulating in the plasma. The fact that the lamb's red cells when sensitized with this free antibody were rapidly eliminated from the circulation of the lamb when it was 2 months old would suggest that the protective mechanism might lie in the mode of action of the reticulo-endothelial system of the newly born lamb or a deficiency in some serum factor which causes destruction of sensitized cells.

RADIOBIOLOGY

Strontium-90 in Human Teeth

THE ultimate concern in strontium-90 fall-out monitoring is the amount of the nuclide assimilated in man. Several world-wide studies have been made to determine the concentration of this fission-product in human bone. Kulp[1] defined the strontium-90 content of bones of children and adults up to 1959, while Bryant published similar United Kingdom bone results for 1958 [2,3] and early 1959 [4].

Since bone is usually obtained at autopsy, sample collection is limited and complicated for local studies. Strontium-90 analysis of human teeth, especially deciduous teeth, is simpler from the point of view of collection and preparation.

Kalchar[5] first suggested a world-wide deciduous tooth radiation census. He stated that strontium-90 assays of teeth would reflect the fall-out level at or near the time of birth. There is some evidence that teeth may also reflect, to a lesser degree, fall-out levels up to the time of removal. Armstrong[6] and other investigators found calcium-45 and phosphorus-32 in mature animal teeth shortly after administration of the radionuclides. The relative amounts of uptake of these radionuclides were: bone > dentine > enamel.

The growth chronology of deciduous and permanent teeth was reported by Wheeler[7]. Each type of tooth has a different chronology, and there are also variations between individuals. Deciduous teeth begin to form before birth, but enamel and roots are not completed for many months. Permanent teeth are not completely calcified for several years after eruption.

Only a few teeth analyses have been reported, due to insensitive methods of analysis and relatively small amounts of strontium-90 in teeth formed in the early 1950's. The highest result of three analyses reported by Hardy[8] was 0·79 ± 0·12 μμc. strontium-90/gm. calcium.

Bryant[9] recently reported the strontium-90 content of sound 9- to 13-year permanent premolars and 16- to 21-year third molars. The strontium-90 concentration for both groups lay in the range 0·1–0·4 μμc./gm. Although there was a rough inverse correlation with age, he reported that the material was too limited to be biologically significant.

The method used by Bryant is typical of most strontium-90 procedures used to date. After addition of strontium carrier, the strontium-90 and natural calcium from 40-gm. batches of teeth were precipitated as oxalates and then as carbonates. Strontium was separated from calcium by repeated precipitations as nitrate. Strontium carbonate was finally precipitated and mounted for counting.

Teeth results reported here were obtained by an improved method of analysis. One hundred and twenty-one teeth were collected in late 1959 and combined to 81 samples before analysis. After a minimum of analytical steps, the final strontium-90 content was determined by counting carrier-free yttrium-90. The method was thoroughly investigated and reported in a previous general fall-out survey[10]. Preparation of teeth included an initial 3-min. soaking in 1 : 10 hydrochloric acid to remove surface film, followed by rinsing with distilled water. Fillings were removed and teeth were air-dried overnight before weighing.

Initial experiments proved that direct dissolution of teeth and co-precipitation of calcium and strontium as oxalates were preferable to ashing. Teeth were dissolved in 50 ml. of 1 : 1 hydrochloric acid. After complete solution, the sample volume was increased to 600 ml. by addition of distilled water. Three grams of oxalic acid were added, and the solution was heated to 80–90° C. Oxalates were precipitated by gradual addition of 1 : 1 ammonium hydroxide, while stirring, to *p*H 5–6. After overnight digestion, the precipitate was separated by vacuum filtration through Whatman No. 42 filter paper. The oxalates were fired to oxides in a muffle furnace at 650° C. The final solid was then dissolved in 50 ml. of 0·08 *N* hydrochloric acid, prior to strontium-90 analysis.

Strontium-90 analysis was obtained by counting the carrier-free yttrium-90 daughter, after an extraction procedure. The 50-ml. sample was first stripped of yttrium-90 by two extractions with equal volumes of 20 per cent di-2-ethylhexyl phosphoric acid in toluene. The yttrium-90 daughter of strontium-90 was allowed to build up to the equilibrium-level over a period of two weeks and was then extracted from the original sample with 5 per cent di-2-ethylhexyl phosphoric acid. Yttrium-90 was removed from the organic layer by extraction with 3 *N* nitric acid. The acid was then evaporated and plancheted. All samples were counted two or more times in a low-background counter to verify the yttrium-90 decay.

Results of this preliminary analysis are shown in Table 1. Due to the small number of samples in each age-group, the types of teeth were not reported. The large errors shown in the last column are due to analyses of individual teeth weighing as little as 0·1 gm. This experience indicates that further sample composites should weigh not less than 2 gm.

Table 1. STRONTIUM-90 ANALYSES OF 121 HUMAN TEETH

Age of donors	No. of teeth	No. of assays	d./m. ^{90}Sr/gm. tooth		
			Maximum	Minimum*	Average†
4	5	4	4·4	1·0	2 6 ± 0 6
6	6	8	4·7	0·2	2 1 ± 2 1
7	12	8	6 2	neg.	1·6 ± 0 8
8	17	7	8 2	0·1	1 5 ± 0·8
9 and 10	19	12	6 0	neg.	0·8 ± 0·4
11 and 12	11	9	2 8	neg.	0 8 ± 0 8
13 and 14	7	5	3 1	neg.	0 8 ± 0 2
15–18	5	5	1 4	0·2	0·8 ± 0·3
19 and 20	8	7	0 8	0 1	0·5 ± 0·3
21–30	17	11	1·8	neg.	0 5 ± 0·3
31 and up	14	10	1·3	neg.	0·4 ± 0·2

* Negative assays are those that counted equal to or less than reagent blanks.

† The standard 120-min. counting error is reported for the average assay.

d./m., Disintegrations/min.

A statistical analysis indicates that there is a definite inverse correlation between strontium-90 concentration and age. The significance test for linear correlation ($r = -0{\cdot}32$), based on 81 independent paired observations, reveals that the probability is less than 0·01 that this inverse relationship does not exist. The trend is expressed better, however, in an exponential form of the type :

$$S_c = B \exp(-kA)$$

where : S_c = strontium-90 concentration ; A = age ; B and k = constants.

The strontium-90 results for teeth are compared with those of bone in Fig. 1. The disintegrations/min. values were corrected to μμc./gm. calcium by assuming 40 per cent calcium in teeth. The trend is similar to the probable distribution of strontium-90 in Western man as reported by Kulp[1], and also to the results obtained by Bryant for bone collected in 1958 [2,3].

A New Effect of Ionizing Radiation on Nucleoprotein

An aqueous solution of nucleoprotein, concentration 12 mgm./ml., prepared from calf thymus by the method of Kay, Simmons and Dounce[1], was irradiated with high-energy electrons to a dose of 4 × 10^6 rads. The dose was given in 4 min., and was assumed to be delivered to an oxygen-free solution, the initial 2 per cent of the dose using up all dissolved oxygen[2]. It was noted that immediately following irradiation a white suspension had been formed, and this afterwards collected at the bottom of the tube on standing. When the irradiated and control solutions were analysed it was found that in addition to producing a precipitate, irradiation had degraded amino-acids, purine and pyrimidine bases and deoxyribose sugar. Details of these degradations will be published elsewhere; the present report is concerned with the nature of the precipitate.

No precipitate had been observed when calf thymus deoxyribonucleic acid (DNA) was irradiated under similar conditions[3]. The precipitate was not 'denatured protein' since no precipitate was formed when an aqueous solution of calf thymus histone was irradiated under similar conditions. It was possible that the precipitate could be 'cross-linked' material derived from both the protein and nucleic acid moieties. This possibility would be checked most suitably by irradiating a mixture of histone and DNA solutions. Unfortunately, mixing solutions of DNA (5 mgm./ml.) and histone (7 mgm./ml.) leads promptly to precipitation, presumably of a nucleoprotein complex[4]. As a substitute experiment, a solution containing histone and a mixture of deoxyribonucleotides was prepared and irradiated as described above. No precipitate was observed after irradiation, suggesting that cross-linking did not produce the precipitate obtained on irradiating nucleoprotein.

The most notable property of the precipitate obtained from irradiated nucleoprotein was its insolubility in water, N hydrochloric acid, N sodium hydroxide and $2M$ sodium chloride. The possible nature of the precipitate was discussed with Dr. K. S. Kirby, who suggested, in the light of his work with P. M. Frearson[5], that the precipitate was an acidic protein, and further that it may have small amounts of nucleotides attached to it. The precipitate was analysed as described here, and Kirby's predictions were confirmed. The precipitate contained an acidic protein with purine and pyrimidine bases attached, and so it is not derived from the bulk of the protein present (histone) in the nucleoprotein, but from a residual protein of the type originally described by Mirsky and Ris[6]. The production of this precipitate by ionizing radiation confirms the presence of an acidic protein in the structure of nucleoprotein. Further, in view of the possible role of the acidic protein in maintaining the structure of nucleoprotein[6], and as a site for enzymatic action[7], precipitation of the protein would affect profoundly the structure and function of the nucleoprotein in an irradiated cell.

Solutions of nucleoprotein, after irradiation, were spun, in a bench centrifuge, in the cold, and the clear supernatant solution decanted off. The precipitate was shaken in distilled water, and re-centrifuged. After washing five times the precipitate was freeze-dried. A weighed sample of the dried precipitate was hydrolysed in perchloric acid (72 per cent) at 100° C. for 1 hr. and analysed for phosphorus[8] and for purine and pyrimidine bases[9]. Large amounts of phosphorus were found (Table 1), and assuming it is present as phosphate, accounts for 70 per cent, by weight, of the precipitate. Small amounts of adenine, guanine, cytosine and thymine were found in the hydrolysate (Table 1). The base ratios were different from those of calf thymus DNA, amounts of guanine and cytosine being relatively greater (double) in the precipitate.

A second sample of the precipitate was hydrolysed in $6N$ hydrochloric acid, at 110° C. for 24 hr. and the hydrolysate analysed for amino-acids by two-dimensional paper chromatography. When the chromatograms were dipped into a solution of ninhydrin a large number of ninhydrin-positive spots appeared, their pattern being identical with that obtained when a sample of unirradiated nucleoprotein was analysed in the same way. The ninhydrin-positive spots were eluted and the amounts of amino-acids determined spectrophotometrically[10]. The relative amounts of amino-acids were similar to those for an unirradiated solution of calf thymus nucleoprotein except that the amounts of glutamic and aspartic acids were approximately 50 per cent greater in the precipitate than in the control. The total amount of amino-acids was approximately that given in Table 1, this value being the remainder when the weight of the purines and pyrimidines, as nucleotides, and of phosphorus, as phosphate, was subtracted from the weight of the precipitate.

Table 1. ANALYSIS OF PRECIPITATE FROM IRRADIATED NUCLEOPROTEIN

		μM/mgm.
Bases:	Adenine	0 05
	Guanine	0·08
	Cytosine	0·07
	Thymine	0·08
	Total	0·28
Phosphorus		6·74
Amino-acids (molecular weight = 127)		2·2

The results obtained for the precipitate are consistent with Kirby's postulate[11] of an acidic protein attached to the nucleic acid moiety. The source of the large amounts of insoluble phosphate in the precipitate is not clear at present. It is Kirby and Frearson's experience that the acidic protein is insoluble and will remain in solution only when combined with DNA. If ionizing radiation severs the link between the acidic protein and the DNA, or breaks the DNA chain within a few nucleotides of the acidic protein, precipitation will promptly follow. There are two ways in which this can occur. Radiation can break the DNA chain, randomly along its length, and the acidic protein will be precipitated when breaks occur sufficiently close to it. In this case the G-value (molecules per 100 eV.) for formation of precipitate will be lower than the G-value for chain breaks by a factor which depends on how close to the protein a break needs to be for precipitation to occur. Alternatively, if energy introduced into DNA by ionization or excitation can migrate along DNA, as discussed recently by Prof. J. S. Mitchell[12], the migration will stop at the discontinuities which the acidic protein must represent in the regular structure of DNA. If the transferred energy is sufficient to break the nucleic acid chain, the acidic protein will be precipitated. If energy is readily transferred along the DNA, acidic protein will be precipitated by low doses of radiation.

Dounce[13] has recently discussed data which show that a residual protein is firmly bound to DNA, as first demonstrated by Mirsky and Ris[6]. While the nature of the binding has not been established, Kirby[14] and Dounce[13] have shown that the bonds are not ionic. Transition-group metals may be involved in a chelation-type bond between the acidic protein and the DNA (ref. 14), and the relatively large amounts of guanine are consistent with a bond of the type suggested by Kirby[14].

The amount of dried precipitate obtained was 0·5 mgm./ml. As 20 per cent of this is protein (see Table 1) the precipitate contains approximately 1·4 per cent of the total protein originally present. Before a G-value for formation of the precipitate can be calculated, it is necessary to determine how the yield of precipitate varies with dose, and also to obtain some estimate for the molecular weight of the acidic protein. Whatever the G-value may be, it is likely that this precipitation will play an important part in the biological effects of ionizing radiation, since it would alter so profoundly the structure and function of the nucleoprotein. Kaufman *et al.*[15] have studied several properties of nucleoprotein of onion roots, *Drosophila melanogaster* and calf thymus, before and after irradiation, and demonstrated degradation of the nucleoprotein with a few hundred r. of X-rays. More recently Hagen[16] has reported that whole-body irradiation of rats labilizes the thymus nucleoprotein. The precipitation described above is a possible mechanism for this labilization. Since Hagen obtained labilization with doses as low as 50 r., precipitation of the acidic protein would be an extremely radiosensitive reaction.

I am indebted to Dr. K. S. Kirby for his help in determining the nature of the precipitate. This investigation has been supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the Medical Research Council, the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service. Financial support was also granted by the William Shepherd Fund.

'Nitric Oxide—and Oxygen Effect' in X-irradiated *Shigella flexneri*

IN a number of cases, for example, bacteria and ascites tumour cells, it is known that nitric oxide increases radiation damage in anoxic conditions to a level comparable with that found in the presence of oxygen. The so-called oxygen effect is thus simulated by nitric oxide.

The starting point of the present investigations was the fact that the chemically very active gas nitric oxide has some effect on cell constituents, and the belief that this possibly, indeed probably, might become manifest after removal of free gas and subsequent X-irradiation. It appeared from the literature that the effect of an exposure of aqueous suspensions of bacteria to nitric oxide, followed by its removal prior to irradiation in oxygen-free nitrogen, had not been tested. While the present work was in progress, Howard-Flanders and Jockey[1] published results showing that this experiment had been carried out independently by them. However, their results obtained with the bubbling technique differ from the present ones obtained in a closed system in various respects not only in regard to the pre-treatment effect but also in some other points.

The results of the present series of experiments may be very briefly summarized as follows:

(*a*) Radiation sensitivity in the presence of nitric oxide is increased over that in nitrogen by a maximal factor of 3·2. A similar enhancement is found in oxygen and these results are in agreement with those of Howard-Flanders and Jockey.

(*b*) If the cells are pre-treated in nitric oxide for 30 min. at room temperature and irradiated in nitrogen after removal of free nitric oxide, sensitivity is again greater than in cells not pre-treated.

(*c*) Radiation sensitivity varies with the concentration of nitric oxide applied (up to a maximum value at 10 per cent nitric oxide in nitrogen), during or prior to irradiation. The minimal dose for 10 per cent survival is about 15 k.rads in the presence of the gas compared with about 20 k.rads after pre-treatment. For nitrogen controls this figure is 49 k.rads.

(*d*) Increasing duration of pre-treatment increases the subsequent radiation sensitivity.

(*e*) Cells kept in nitrogen (maximum period about 2 hr.) after pre-treatment with nitric oxide show a constant sensitivity.

(*f*) The pre-treatment effect is not due to residual free nitric oxide because of the evidence quoted in paragraphs (*c*) and (*d*) and also because of the high degree of consistency obtained for the radiation sensitivity in nitrogen.

The conclusion to be drawn from the present results is that the 'nitric oxide' effect seems largely caused by some latent, irreversible injury to unknown constituents of the cells with which nitric oxide may have combined. This injury is revealed on subsequent irradiation. The nitric oxide effect is thus different from the 'oxygen effect', which is only seen when irradiation occurs in the presence of the gas. Furthermore, the effect of time of contact with, and of the concentration of nitric oxide during, pre-treatment does not support the equivalence of nitric oxide and oxygen in their role in enhancing injury by radiation.

A detailed account of this investigation will be published in due course.

Adaptation of a Chromatographic Technique for Autoradiography

A QUALITATIVE chromatographic technique has been previously described[1] which enables the investigation of simple compounds and their distribution in plant tissues to be accomplished without the immediate necessity of preparing extracts (for example, ether–water or alcohol). This method can be further extended by its use with radioactive isotopes and subsequent autoradiography.

Five day-old seedlings of *Phaseolus vulgaris* L., variety Improved Canadian Wonder (with radicles approximately 4–5 cm. long) were injected with 10 µl. of a solution containing 0·4 mc./µl. of sucrose uniformally labelled with carbon-14. In one batch of seedlings (*a*) the sucrose was injected with a micro-syringe into the thickest part of the radicle, and in another batch (*b*) it was injected into the distal end (with respect to the embryo) of one of the cotyledons. The injected seedlings were then allowed to continue to grow normally, each batch being sampled at 1 hr., 2 hr., 4 hr., 1 day, 2 days and 4 days after injection. The sample seedlings were subjected to the chromatographic technique on Whatman No. 3 chromatography paper. After development, using conventional methods and solvents, the chromatograms were dried and placed with sheets of Ilford *G* X-ray film in cassettes and allowed to remain in contact with the films for 3–4 weeks. After this time, radioactive compounds were detected by developing the X-ray plate and could be compared with the compounds on the chromatograms after these had been treated with specific reagents (in this case, ninhydrin to detect amino-acids followed by benzidine–trichloracetic acid to detect the saccharides).

The results showed that in the case of the embryo-injected seedlings (*a*), the sucrose pool in the embryo became labelled and also the pool of reducing sugars, glucose and fructose. Various amino-acids were rapidly labelled and also (high molecular weight) material which did not move from the starting line of the chromatogram. Eventually, after four days, only small amounts of the labelled saccharides and amino-acids remained although considerable quantities of these compounds (unlabelled) were still evident on the chromatograms (that is, in the embryo). The majority of the radioactivity was found to be associated with the material at the starting line of the chromatogram. In the case of the cotyledon-injected seedlings (*b*), the cotyledon sucrose pool was labelled, but the evidence suggested that only amino-acids and 'high-molecular weight' material became further labelled; no reducing sugars became labelled. However, there is little reducing sugar in the cotyledons during germination (approx. 0·05–0·1 per cent dry wt.)[2].

In both cases (*a*) and (*b*), the labelled sucrose was found to appear in the other parts of the plant as well as in the injected part, but to a lesser extent in case (*a*) than case (*b*). This observation could possibly mean that sucrose can be translocated in both directions in the plant (that is, cotyledons to embryo and vice versa); this is consistent with the findings of Rabideau and Burr[3], of Chen[4], and of Palmquist[5] who observed that solutes can be translocated in both directions in the stems of *P. vulgaris* and other plants. Nevertheless, the net flow of sucrose was in the direction cotyledons to embryo as would be expected.

In case (*b*), injected cotyledons, as well as the labelled sucrose which appeared in the embryo, labelled glucose and fructose appeared in the reducing sugar pool of the embryo. This could be consistent with the fact that an invertase (optimal activity at *p*H 5·0) can be extracted from this part of the plant at these stages of germination (ref. 2 and Cooper, R. A., and Greenshields, R. N., unpublished results, 1960).

It is proposed in future work to inject other carbon-14 containing compounds into this plant, for example, galactose-^{14}C and raffinose-^{14}C, to determine the fate of these compounds on germination. The raffinose family of oligosaccharides (namely, verbascose, stachyose, raffinose and sucrose) occur in this plant[6] and rapidly disappear on germination, leaving only sucrose in the cotyledons and sucrose, glucose and fructose in the embryo (that is, no galactose)[2]. Thus the fate of the galactose might be determined.

Although effects due to 'cut-respiration'[7] cannot be overcome, because the pattern and changes of the saccharides in untreated plants is the same as in treated plants, the effects due to 'cut-respiration' are probably very small. Furthermore, in the case where injected radioisotopes are translocated to other parts of the plants, for example, sucrose appearing in the embryo after injection in the cotyledons, 'cut-respiration' would not complicate the interpretation of the results.

Thus it can be seen that this technique might provide a useful tool in helping to solve translocation problems and also to indicate possible reactions that occur *in vivo*. Although purely qualitative, the technique indicates lines along which quantitative work might be pursued.

Effect of pH on the Sensitiveness of Trypsin to Ionizing Radiation

ALTHOUGH oxygen usually increases the sensitivity of biological systems to ionizing radiations, it was found that with the enzymes chymotrypsin[1] and trypsin[2], in dilute aqueous solutions, the presence of air as compared with vacuum diminished the sensitiveness by a factor of about 3. In these experiments the enzyme was dissolved in 10^{-3} *N* hydrochloric acid, in which it was believed to be most stable. We have now, in the case of trypsin, examined the effect of varying the *p*H of the solution in which it is dissolved and find that the effect of oxygen is markedly dependent on the *p*H. Some typical figures of the specific inactivation dose to 220-kV. X-rays are given in Table 1 (in rads/gm./ml.).

Table 1

Solvent	0·1 *N* HCl	0·01 *N* HCl	0·001 *N* HCl	Water
*p*H (approximate)	1	2	3	6
D_{37}/c. in air ($\times 10^{-4}$)	0·3	1·0	1·5	1·0
D_{37}/c. *in vacuo* ($\times 10^{-4}$)	0·25	0·4	0·6	1·0

It can be seen that the difference between the sensitiveness *in vacuo* and in the presence of air is a maximum at about *p*H 3 and diminishes both in more and in less acid solutions. Increasing the chloride ion concentration without changing the *p*H had little effect.

In order to explain this behaviour we must consider the reactions:

$$H + O_2 \rightarrow HO_2 \qquad (1)$$

$$HO_2 \rightarrow H^+ + O_2^- \text{ (}pK\text{ between 2 and 3) (ref. 3)} \qquad (2)$$

$$H_2 \rightarrow H^+ + H \text{ (}pK\text{ between 1 and 3) (ref. 4)} \qquad (3)$$

It can be seen that at $pH > 3$ (approximately) HO_2 will be present under equilibrium conditions mainly as O_2^-, which, like H, is a reducing agent. In so far as we are concerned with oxidation-reduction effects, no great change will be brought about by the presence of oxygen. At $pH < 3$, HO_2, which is an oxidizing agent, will be present in an undissociated form, and it is evident that this is less effective than H or O_2^- in causing inactivation of the enzyme. At still lower pH (~ 2), the formation of H_2^+ begins to be effective, and in this region there will be a competition between H^+ and O_2 for the available H radicals, so that the amount of HO_2 will be diminished. As H_2^+, like H, is a reducing agent, it follows that the effect of oxygen may be expected to be diminished again at low pH.

This investigation has been supported by grants as in ref. 2.

BIOLOGY

Survival of Cutaneous Homografts after Transplantation of Lymph Nodes immunized against the Host

Up to now, two main experimental methods have been established to overcome tissue incompatibility in genetically different individuals. One of them is the acquired tolerance in embryogenesis or shortly after birth[1,2], and the other consists in X-ray irradiation of the host with the lethal dose and a life-saving bone-marrow transplantation[3].

In this communication I should like to demonstrate a new approach to overcome tissue incompatibility by influencing the regional lymphatic system with the transplantation of lymph nodes immunized against the host.

I have experimented on rabbits (chinchilla and albino breed) weighing 2,000–2,500 gm. Experiments were performed on three groups within one year. Each group comprised 15 rabbits, five of them being recipients of skin (rabbit *A*, chinchilla), 5 donors of nodes immunized against the recipient (rabbit *B*, albino) and 5 donors of skin (rabbit *C*, albino) (Fig. 1).

From the left ear of the future recipient (*A*) a skin flap 2 cm. × 2 cm. was grafted on the ear of the lymphatic node donor (*B*). One week after the skin graft I extirpated the lymph node from the collecting area of the ear, cut it in thin slices and transplanted it subcutaneously into the base of the recipient's ear (*A*) and, at the same time, grafted the skin of the donor's ear (*C*) on that site.

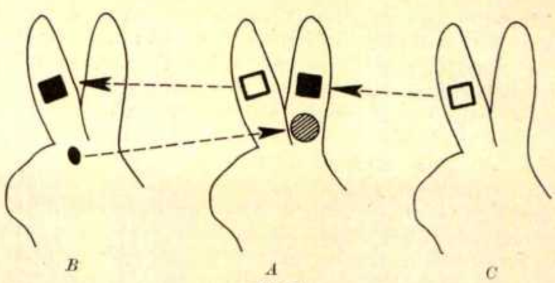

Fig. 1

I have studied the survival of the graft only macroscopically because it differed in colour from the skin of the host. I assessed the result statistically with a *t* test against the control groups in which I simultaneously transplanted on host *A* the node without antibodies against the host and a graft from donor *C*.

The results are summarized in Table 1. In all cases I was able to achieve a statistically extraordinary long survival-rate of the graft. In controls, the graft was rejected between the eighth and the thirteenth day. In the groups after treatment of the regional lymphatic system of the host by antibodies against the host with a transplanted regional lymph node the grafts were rejected in twelve cases between the fifty-fourth and the eighty-sixth day. In three rabbits the graft survived practically permanently.

Table 1. Survival-Rate of Skin Homografts on a Rabbit's Ear

Control group	Influencing of the host with antibodies against the host	Control group	Influencing of the host with antibodies against the host
8	54	12	70
8	58	12	70
9	62	12	79
10	62	12	86
10	63	13	187 (+)
10	67	13	350 (still alive)
11	69	13	746 (still alive)
11	70		
Average : 10·9 ± 0·3	average of the first 12 animals 67·5 ± 2·5		

In one rabbit from the first group, the graft has survived to this day, that is, two years since November 1958 (Fig. 2). In another rabbit from the second group the graft survived macroscopically for six months in perfect condition before the rabbit died of pneumonia. A third graft from the last group is surviving in one-quarter of the original graft for almost one year now in a good condition, that is, since December 1959.

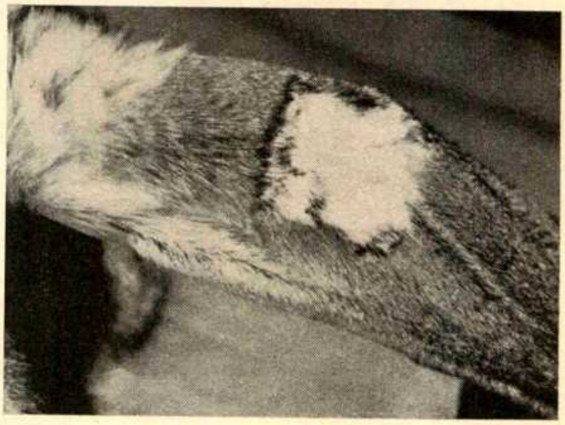

Fig. 2. A homograft two years after the transplantation

The importance of the lymphatic system for achieving transplantation immunity has been differently interpreted in the literature. While the majority of papers stress the changes of the regional lymphatic system after homografts[4] there are also papers categorically denying its importance[5]. In an earlier paper I have attempted to point out the importance of the regional lymphatic system in establishing transplantation immunity. After extirpation of the regional lymphatic system or its destruction by means of *TS* 160 (nitrogen mustard), the survival-rate of the graft could be prolonged for 15–65 days[6].

The results of treatment of the regional lymphatic system with antibodies against the host seem to be important for a new approach to overcome tissue incompatibility.

A Method of determining Embryonic Orientation in the Hen's Egg

I wish to report a successful attempt at detecting embryonic position in the hen's egg using, so far as it is known, a previously untried technique. It consists of X-raying the incubated egg to determine the skeletal morphology of the embryo. With the egg held in a horizontal position the embryo's longitudinal position can be easily detected. On rotating the egg through a 90° angle, exposing it a second time, and then viewing the X-ray plates in the order of taking, the direction in which the head is turned can be accurately determined.

In this way, not only can the normal orientation of embryos be studied but also the lethal nature or hatchability of certain conventional malpositions about which controversy[1] has arisen in the past, since the technique does not involve the death of embryos.

Fig. 1 shows the normal position adopted by embryos approximately 36 hr. before hatching is completed; the long axis of the embryo coincides with that of the egg and the head and beak are turned to the embryo's right across the breast towards the broad end of the egg and in close proximity to the air cell (clearly defined dark area). In Fig. 2 the longitudinal position of the embryo is reversed so that the head is seen towards the small end of the egg away from the air cell, into which it is normal for the embryo's beak and head to enter during the process of hatching.

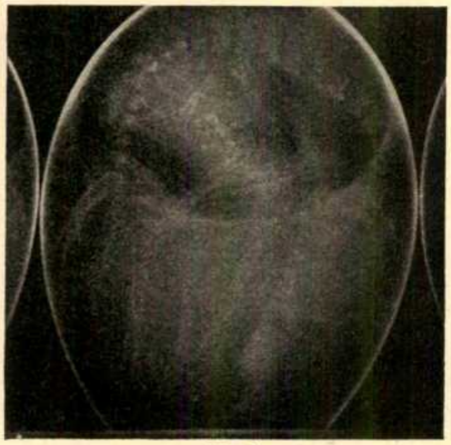

Fig. 1

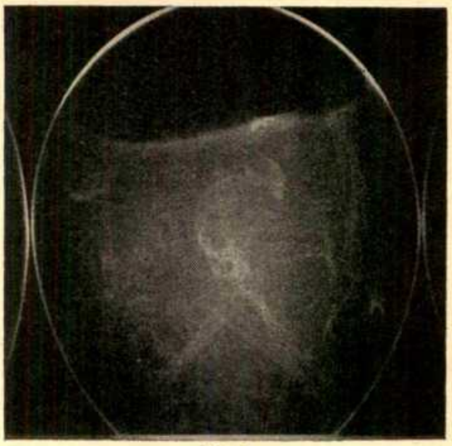

Fig. 2

Detailed results of this work will be reported in the near future; but, for the present, work has shown that (*a*) the head-between-thighs position of malposition I should be regarded as a transitional stage in the normal orientation of embryos to the hatching position rather than a cause of death or failure to hatch, and (*b*) embryos adopting malposition II (head in the small end) or malposition III (head to left) have, respectively, a slightly better than one in two and one in five chance of hatching.

Effect of Temperature and Grafting on Vegetative Growth Phases of Algerian Ivy

The closely similar English and Algerian ivies, *Hedera helix*, Linn. and *Hedera canariensis*, Willd., do not flower until the juvenile vining type of growth changes into a stiff erect form. This mature type of growth has entire, ovate to lanceloate leaves, and the round stems rarely produce aerial roots. The juvenile trailing stems are somewhat flattened, frequently produce aerial roots, and the leaves are palmately lobed. Both stems and petioles frequently have red pigments. Doorenbos[1] was able to produce many reversions to the juvenile form by grafting the mature fruiting form of English ivy on juvenile two- or three-year seedlings or on juvenile plants grown from cuttings. Plants of adult ivies grown on juvenile understocks for approximately a year outdoors in a lath house in the relatively cool coastal climate of west Los Angeles did not exhibit the reversions described by Doorenbos. Preliminary experiments indicated that mature budded plants on juvenile understocks all reverted to the juvenile form when grown for more than a year at 80° F. but produced few reversions at lower temperatures.

Table 1. GROWTH RESPONSES IN THREE ENVIRONMENTS

Environment	Total plants observed	Plants with adult characters	Plants with juvenile characters	Total No. of shoots	Average shoot length (cm.)
Lath house	66	45	21	155	23·55±1·04
Glasshouse, 60° F.	60	51	9	165	24·45±1·18
Glasshouse, 80° F.	60	0	60	96	25·94±1·52

Closely similar results were obtained in a more extensive experiment started on February 19, 1959, using budded plants of Algerian ivy. The plants were distributed among the three environments on April 20. The glasshouses were air conditioned with automatic controls. On May 4 the natural buds of the stocks were excised to force growth from the inserted buds. On September 14 the plants in both the lath house and the 60° F. glasshouse were predominantly adult and were showing flower buds, but in the 80° F. glasshouse the growth was largely juvenile. The plants were headed back on September 29 to about 6 in. above the bud union. Final results were taken on November 16 and are shown in Table 1. The highest temperature did not increase the length of shoots appreciably, reduced the number of shoots, and promoted reversions to the juvenile type of growth. During this experiment, 26 own-rooted, cutting-grown plants of the mature form of the same clone were kept in each of the same three environments. No changes in type of growth occurred, except that in the glasshouse kept at 80° F. two plants produced shoots with some juvenile characters. On own-rooted mature plants, reversion shoots occasionally appear and are nearly always produced close to the level of the soil.

The amount of mature scion wood initially in the graft combination also influenced the responses. This was demonstrated in an experiment with a clone of Algerian ivy grafted or budded on a juvenile clone of the same species. The plants were started on August 24, 1959, and were placed in the three environments used in the preceding experiments. Buds were excised from the understocks on November 17 in order to force top growth. Growth of the plants in the lath house was slower, but the shoot growth was closely comparable in the two glasshouses. The plants were classified on March 25, 1960. The results are shown in Table 2. These responses show that the greater quantity of the mature type of wood on the scion in grafting diminished the reversions to juvenile growth.
